Suspended in the C & C shaft at the 2500-ft. level are two vertical turbine pumps which were manufactured by the Byron Jackson Co. and are driven by two General Electric 200-hp. 440-volt motors. Each unit has a capacity of 2200 gal. per minute. One of these units is in constant operation and the other is held as an auxiliary in case of accident to the operating unit. About 1500 gal. of water per minute is pumped from the 2500-ft. level to the 2310-ft. station.

station pump directly to the upper Riedler tank which is the feed tank for the Riedler pumps. By this change the continuous use of these air-lifts has been eliminated and an economy affected thereby.

The scope of the work being done by the Pumping Association may be judged by the following weekly report. The Riedler pumps on the 2000-ft. station ran as follows: No. 1, 119 hours, 35 minutes; No. 2, 146 hours; No. 3, 59 hours, 50 minutes. The centrifugal pumps on the 2310-ft. station ran as follows: No. 1, 165½ hours; No. 2, 99¼ hours; No. 3, 65 hours. The shaft pumps on the 2500-ft. level ran as follows: No. 1, 56 hours; No. 2, 109 hours.

The 2500-ft. north drift, started from the winze

station at a point 565 ft. east from the shaft station, was cleaned out, and repaired a distance of 10 feet. Three tunnel sets of timbers were put in at the connection with the southwest drift. At this point the ground is badly caved, and must be thoroughly timbered before work can be continued. Total length in repair from the winze station is 455 ft., and the total distance from the shaft station is 1020 ft., the face being in caved ground. The ventilation of the 2500-ft. drift is greatly improved since the

VERTICAL TURBINE PUMP USED AT 2500-FT. LEVEL.

connection was made with the southwest drift. Water was held at all points.

Following is a statement of the cost of operation from December 1, 1912 to June 1, 1913:

Month.	Regular expense.	Extra expense.	Total expense.
December	\$16,581	\$3,138	\$19,720
January	17,393	3,000	20,393
February	15,850	2,209	18,058
March	15,363	870	16,233
April	14,437	841	15,278
May	13,712	1,944	15,656

The items comprising the regular operating expenses include salaries, labor, supplies, power, water, hoisting, compressed air, all repairs on the pumps and the pumping system, and the general expense of maintaining the Association. All supplies used, with the exception of the ladders, which were taken from the Ward shaft, have been charged in the above account. The extraordinary and installation expenses comprise such items as the cost of the Mexican-Ophir winze winches, damages through personal injury, cost of removing hydraulic elevator, repairing and preparing the C & C shaft for the lowering of the 2500-ft. turbine pump, testing and installing this pump, repairing the 2500-ft. station and east drift, etc. The principal cause of the greatly re-

duced expense since my appointment on January 25, 1913, is the fact that the efficiency of labor has been raised and the work conducted with fewer men. Many changes have also been made in the operation of the pumps which were along the lines of economy.

Included in the statement of costs is a water bill which amounts to \$2500 per month. The water contract gives the Association the use of 200 miners inches of water, which was consumed when the Association operated the Evans hydraulic elevators. As soon as the electrically driven turbine pumps were installed on the 2310 and 2500-ft. stations the operation of the elevators was discontinued, and there is no immediate use for this pressure water.

Progress at Panama

The grand total of canal excavation to July 1 was 203,383,539 cu. yd., leaving to be excaevated 14,812,-034 cubic yards.

The total excaevation for the month of June was 2,659,424 cu. yd., as compared with 2,339,770 cu. yd. for the corresponding month last year, and 2,646,442 cu. yd. in June 1911. The dry excaevation for the month amounted to 1,152,299 cu. yd., entirely by steam-shovels. The dredges removed 1,507,125 cu. yd., nearly attaining the total of the previous month, 1,525,493 cu. yd., which was the highest of record on the canal. In the Atlantic division, the total excaevation was 814,980 cu. yd. Of this amount, all but 388 cu. yd. consisted of material dredged from the Atlantic entrance and approach to Gatun locks. The total excaevation in Central division territory was 878,300 cu. yd., 57,274 cu. yd. of which consisted of hydraulic excaevation, back of Gold hill, performed by the forces of the Fifth division. Central division shovels removed 821,026 cu. yd., as follows: 805,109 cu. yd., classified as primary excaevation from Culebra cut; 13,017 cu. yd. charged to plant excaevation, and 2900 cu. yd. from the drainage ditch between Empire and Culebra on the west bank. The total excaevation from the Culebra cut section in June 1912 was 1,348,780 cu. yd. In the Pacific section, the total excaevation was 966,144 cu. yd., 330,-885 cu. yd. by steam-shovels, and 635,259 cu. yd. by dredges. The dry excaevation consisted of 229,894 cu. yd. from the canal prism, south of Miraflores locks, and 100,991 cu. yd. from the terminal site. The wet excaevation consisted of 604,080 cu. yd. from the Pacific entrance, between the dike and the sea, and 31,179 cu. yd. from the terminal basin.

H. D. Avis' patent for coating aluminum or its alloys for soldering is as follows: Chlorides of tin and zinc are mixed in the ratio of 2 to 3 parts of the former to 1 of the latter. The mixture is heated and excess of hydrochloric acid is expelled. On cooling, the mass becomes of a pasty consistence, after which a small amount of powdered tin is added. To tin the surface of the aluminum this paste is applied and the parts are heated below redness. When the proper temperature is reached, the aluminum is coated with the oxide of tin and zinc, which on removal with a brush or other means leaves a bright film of tin. The soldering is a simple matter.

Metallurgy at Broken Hill

By J. MALCOLM NEWMAN

*At the recent meeting of the Australasian Institute of Mining Engineers at Broken Hill, many valuable mining and metallurgical papers were read, especially on the subject of metallurgy. Broken Hill mines have produced a total of \$360,000,000 to date, and paid \$87,000,000 in dividends, of which the Broken Hill Proprietary has contributed 50 and 65%, respectively. The nominal capital of companies contributing is about \$28,000,000. It is as well, perhaps, at the outset to describe the average Broken Hill ore. The unaltered ore consists of a mixture of galena, blende, quartz, rhodonite, garnet, calcite, and pyrite. The galena is almost pure argentiferous lead sulphide, while the blende is an impure zinc sulphide, combined with sulphides of iron and manganese. The percentages of rhodonite and calcite vary at different points along the line

in jigs, tables, and vanners, producing high-grade galena concentrate, and as by-products, zinc, middling, tailing, and slime.

1901 to 1907.—Mechernich magnetic process, treating rich zinc middling produced by water concentration for the recovery of the following products: (1) garnet, rhodonite product, waste; (2) blende product, a marketable concentrate; (3) galena, blende, quartz products, which on further treatment on wet concentrating tables and vanners, produced lead concentrate, zinc concentrate, and waste quartz product. The wet mill tailing and slime were not treated by this process.

1901.—Experiments on flotation by frothing conducted at the Central mine without commercial results.

1901 to 1902-3.—Potter and Delprat processes.

INTERIOR OF REFINERY.

MOLDING MARKET LEAD.

of the lode. For instance, the north end of the North mine, the south end of the South mine, and the whole of the South Bloeks mine yield calcite ores, and contain less than 5% of rhodonite. The rhodonite percentage on the other mines varies from about 15% in the Proprietary to 45% in the Junction North.

Concentration Problems

The higher specific gravity of galena ore enables a large percentage of that mineral to be recovered by jigs, concentrating tables, and vanners, but owing to the fact that the specific gravity of blende differs very little from that of garnet and rhodonite, it is impossible to make a separation of these minerals by water concentration alone. The Broken Hill garnet has a specific gravity of about 4.2; the blende, about 4.0, and the rhodonite about 3.6. James Hebbard, of the Central mine, submitted a historical account of nearly twenty years' struggle to solve the problem of segregating the lead, zinc, and silver of the ores into products capable of being marketed and smelted commercially. The chronology is as follows:

From 1895 to present date.—Water concentration

In these, hot solutions, containing sulphuric acid and salt cake (acid sodium sulphate) respectively, are applied to fine granular ore or tailing, producing carbon di-oxide gas, which floats off the galena and blende, leaving the quartz and rhodonite behind. This process has been commercially successful in treating middling and tailing but will not without modification treat slime. It is limited also to the rhodonite ores, containing only a small percentage of calcite, because of the solubility of calcite in sulphuric acid.

Cattermole Process

1904 to 1905.—The Cattermole or granulation process, consisting in the agitation of a mixture of pulped ore, oil, and water, containing a suitable acid or an alkali with soap or other emulsifying agent, so as to agglomerate the oil-coated particles into granules. The oil was thus employed in a state of emulsion in water in the presence of an emulsifying agent, such as soap. After agitation, the mixture was passed into an up-current separator or classifier to remove the lighter non-oil-coated particles from the agglomerated masses of oil-coated particles. The lighter sand having been eliminated, the pulp passed to a second series of agitators to increase the size of granules, and thence

*Abstract from *Australian Mining Standard*.

to a second classifier for the removal of the heavy sand. From the bottom of this second classifier some granulated concentrate was recovered, but the heavy sand from the overflow also carried over with the up-current a large amount of granulated mineral. This mixture of granulated mineral and heavy sand passed then to a third series of agitators, and thence to a shaking table, where the granulated mineral, rendered more buoyant by directing on to the surface of the moist pulp jets of compressed air, was buoyed to the surface of the water, and floated off the bottom of the table, while the gangue sank and was delivered over the end of the table. The plant for this process consisted of: (1) grinding apparatus; (2) vat for emulsifying various oils; (3) set of six mixers in series; (4) up-casts for separating sand and float; (5) second set of mixers for further aeration; (6) up-casts for further separation of sand and float; (7) third set of mixers for re-aeration; and (8) Wilfley tables for the separation of coarse sand from granulated sulphides.

This process is especially noticeable as being the first process to treat slime successfully.

Mineral Flotation

1905 to 1906.—Frothing process (flotation), developed in connection with the granulation process. It was found that by lowering the percentage of oil a mineral froth was produced as distinct from the granules produced with a higher percentage of oil. Based on this fact, Messrs. Sulman, Picard, and Ballot took out their patent under which finely powdered ore suspended in acidified water is mixed with a small proportion of an oil substance, such as oleic acid, amounting to a fraction of 1% on the ore, and agitated until the oil-coated minerals form into a froth which can be separated from the gangue by flotation. Heat may be applied to facilitate oiling, and either shaking tables or spitz boxes may be used to separate the frothy mineral from the sand and the gangue slime. This was followed by Mr. Chapman's patent, under which, (1) the ore, suitably crushed, is agitated with acidified water in the first mixer and heated, (2) oleic acid is subsequently added in the second vessel; (3) the pulp is maintained at the desired temperature in the third and following mixers with violent agitation in each mixer to ensure complete and thorough emulsion.

1907.—A slime plant, started at the Central mine, treating accumulated dump material, closed down after treating 40,000 tons.

1908 to 1911.—A Minerals Separation plant treated 710,000 tons of Central mine accumulated tailing.

1909 to present date.—Zinc department added to the wet mill on the Central mine, treating all the by-products of the wet mill. It may be mentioned that up to January, 1913, this plant has treated 1,225,011 tons of ore, and recovered 239,408 tons of lead concentrate and 399,090 tons of zinc concentrate. In addition to the progress described by Mr. Hebbard, the following, which was done at mines other than the Central, have had far-reaching results, namely:

1903 to present date.—The Broken Hill Proprietary Co. has worked the Potter-Delprat process on a large scale, treating old accumulated and current mill tailing, but not slime. The capacity of the plant is 12,000 tons per week.

1907 to 1912.—The Elmore vacuum oil process worked at the Zinc Corporation treating old tailing with a capacity of 700 tons per day. It was also in operation on the British mine. On both these properties the Elmore has been replaced by the Minerals Separation process.

1910 to present date.—The Amalgamated Zinc (De Bavay) Co. is treating 11,000 tons of tailing per week by the De Bavay skin float process, which depends on the property of greased particles of sulphides floating as a film on the surface of the water. This process, though entirely successful on granular material, does not treat slime.

1911 to 1912.—Bradford's slime process at Broken Hill Proprietary mine. A modified Potter acid process, depending on the principle of enclosed agitation and aeration. This process treated accumulated slime dumps, and had a capacity of 2500 tons per week.

The foregoing is then the history of the struggle, the net result of which has been the large increase in recovery of metals stated by Mr. Hebbard to be as follows: recoveries in 1895, silver, 45%; lead, 65%; zinc, 7%; and, recoveries in 1912, silver, 92.7%; lead, 94.1%; and zinc, 91.8 per cent.

Central Mine

Based on these recoveries, the figures given by Mr. Hebbard, summarizing the work done in the Central mill during the twelve months ended December 28, 1912, show a metal value extracted from the ore of over \$33.60 per ton of ore at recent metal prices. Allowing, say, \$16.80 for Broken Hill costs and profits, it is shown that \$16.80 per ton of ore, or \$33.60 per ton of combined lead and zinc concentrate, is required to cover the smelting charges and smelting losses. It is well known that smelting, of zinc ores in particular, is expensive, and that some metallurgical loss is unavoidable in all smelting operations, but \$33.60 per ton of concentrate strikes one as an exceptionally high figure. The spelter convention and metal brokers can, no doubt, be blamed to a certain extent, but of course the great source of loss lies in the fact that the various Broken Hill concentrates are still complex in composition, with the following results: (1) The lead concentrate contains from 6 to 10% of zinc, which not only is not paid for by the smelting companies, but is charged for in their returning charges; (2) the silver in the zinc concentrate is subject to a big reduction from the assay, the remainder only being paid for at about 50% of its value; and (3) the lead in the zinc concentrate is subject to deduction from the assay, and the remainder is then also only paid for at about 50% of its value.

Further treatment of slime is to be done by the selective or preferential flotation processes.

Gold production of Queensland in May was 23,509 fine ounces.

Precipitation of Gold in Orebodies

Some interesting experiments on the condition of gold occurring in quartz have been made by P. Von Veimarn, who reports in *Zeitz. Chem. Ind. Colloide*, Vol. 11, p. 287, that by mixing equal volumes of 0.1 to 1% solution of NaAuCl and Na_2SiO_3 there was a gradual change in color from the yellow of AuCl_3 to colorless, then rose, lilac, and blue. A precipitation began to appear after about one year; coagulation being very slow and the solution remaining colored for a long time. This is explained as due to the formation of an unstable gold silicate which suffers self-reduction. The colorless filtrate from the precipitation of colloidal gold on evaporation to dryness gave a purple-red colored layer of silicic acid. Ultramicroscopic examination shows that the dispersed gold is so intimately mixed with the silicic acid that it cannot be recognized in the form of separate submicrons. It is quite possible that the natural occurrence of gold in quartz may be explained by such a series of changes.

In studying the secondary precipitation of gold in orebodies, Albert D. Brokaw (*Journal of Geology*, Vol. 21, p. 251) concludes that ferrous compounds derived from the oxidation of sulphides are the most important substances in causing precipitation of gold. In most deposits sufficient pyrite, or other iron-bearing sulphides are present in the primary ore to precipitate any gold that may be brought in. Less commonly siderite or iron-bearing calcite may be important. Siderite is readily attacked by acids and yields iron salts. In rare cases when gold is in a solution containing manganese salts, contact with the country rock may neutralize the acids present and allow the manganese to reduce the gold. Rhodochrosite resembles siderite in its action except that no precipitation of gold can occur if solutions are strongly acid, while in the case of siderite acidity does not prevent the reduction.

Influence of Metallic Minerals on Precipitation

A more elaborate study of the rôle of certain metallic minerals in precipitating silver and gold has recently been made by Chase Palmer and E. S. Bastin, of the United States Geological Survey, and appears in the *Bulletin* of the American Institute of Mining Engineers, page 843 (1913). Their preliminary experiments show that certain sulphides, arsenides, and sulph-arsenides of copper, nickel, and cobalt precipitate metallic silver very efficiently from dilute aqueous solutions of silver sulphate. As the waters descending through the upper portions of most sulphide orebodies are known to be sulphate waters, similar precipitative actions would be expected under certain natural conditions. The frequent association of silver in ore deposits with chalcocite and bornite, and particularly with niccolite and cobaltite, minerals which in these experiments were among the most efficient precipitants, warrants the belief that such reactions are of importance in secondary enrichment of orebodies.

The more common sulphides, such as pyrite, galena, and sphalerite, are relatively inactive as pre-

cipitants of silver from aqueous solutions of its sulphate.

The quantitative results obtained with niccolite and chalcocite indicate that the essential chemical changes in reactions of this type are due to oxidation through the hydrolytic action of water. It is apparent, therefore, that certain water solutions may act as potent oxidizing agents below the ground-water level.

Unlike gold, silver forms a large number of natural compounds. It is probable that the presence of certain other substances in the vein solutions, notably arsenic and antimony, may so modify the reactions that silver is precipitated not as native metal but as a compound such as polybasite or proustite. The conditions under which such compounds are made forms an allied and very important field of research.

The experiments indicated that nearly all of the sulphides and arsenides common in ore deposits were capable of reducing gold from a solution of its chloride, although the important differences in the rapidity of the precipitation were observed with different minerals. Most of the minerals that are especially efficient as precipitants of silver are also effective precipitants of gold, and a number of other minerals, such as galena, pyrite, stibnite, and millerite, that are inefficient in precipitating silver are efficient in depositing gold.

Chloride-Bearing Waters

It is known that the waters descending through the upper portions of sulphide orebodies universally carry chlorides, and it is probable that these chlorides have effected the solution of the gold. It is probable, therefore, that phenomena similar to those exhibited in the experiments with gold chloride solution play an important part in secondary enrichment in gold.

While the phenomena described find their most immediate application in secondary enrichment, it is perfectly possible that such reducing effects of the sulphides may be responsible in part for the primary association of the precious metals with certain sulphides in preference to others. It is recognized, of course, that certain mineral associations in ore deposits are probably the result of processes analogous to differentiation in rock magmas, but it is quite possible that other associations, such as the apparent preference of gold for chalcopyrite and tetrahedrite rather than for pyrite in deposits carrying these three minerals, may be due to differences in the reducing power of these sulphides themselves. Light could probably be thrown upon this point by the investigation of the reducing effect of various sulphides upon silver and gold salts dissolved in solutions having the composition of certain deep mine waters. The effect of increase of temperature on the reactions should also be studied.

It is a generally recognized fact that the purity of alluvial gold is greater than that of the veins in the neighborhood. This superiority in fineness has generally been explained by the well known fact that silver is more readily soluble in natural waters than gold, and is by them removed from the natural alloy, thus increasing its purity. Waldemar Lindgren

has recently discussed this matter at some length in a report on the Tertiary gravels of California,* and has presented a large number of statistical data leading to the same conclusion. It has been thought by certain geologists that this refinement of the gold was accomplished by solutions circulating through the gravels themselves, but Mr. Lindgren states that "so far as the Tertiary gravels of California are concerned, the conclusion of the writer is that solution and precipitation of gold have played an absolutely insignificant part." Under the conditions of the experiments here reported it was found that nearly all of the metallic minerals common in precious metal deposits were capable of precipitating gold, while a much smaller number, and these not the most common ones, were active precipitants of silver. When it is remembered that the source of the placer gold is the oxidized zone of the original deposit, and that the gold may have been dissolved and redeposited several times within the vein before erosion carried it into the alluvium, it seems probable that such selective precipitation may be a factor in this natural refining of gold.

Mineral Production of New York

The following table shows the output in 1912, this being valued at \$36,519,382, an increase of 17% over the total for 1911, according to John M. Clarke, state geologist:

Product.	Value.
Clay materials	\$11,947,497
Stone from quarries	5,718,814
Cement (4,783,535 bbl.)	3,631,097
Iron ore (1,277,677 long tons).....	3,349,095
Salt (10,502,214 bbl.)	2,597,260
Petroleum (782,661 bbl.)	3,220,647
Natural gas (6,564,659,000 cu. ft.) }	
Gypsum (506,274 tons).	

Among the minor industries, in some of which the state of New York has a prominent place by reason of its abundant natural resources, are those of talc, garnet, graphite, pyrite, mineral waters, millstones, feldspar, slate, and sand. Their record for the year was not attended by any unusual features.

Oil, Gold, and Coal Production of the Dutch East Indies

The production in 1912 of the oil wells in Dutch East Indies was as follows, in tons of 1016 kg., or 2239 lb.: Java, 184,809; North Sumatra, 379,014; South Sumatra, 259,215; and Borneo, 671,662.

The following figures give the production of the principal gold mines: Redjang Lebong (Sumatra), \$1,223,925; Simau (Sumatra), \$764,040; Ketahoen (Sumatra), \$233,600; Totok (Celebes), \$208,040; and Paleleh (Celebes), \$368,637.

The production of the Government coal mines at Ombilien, Sumatra, was 408,204 tons, as against 406,508 tons in 1911. An electric plant for the bunkering of steamers at Padang has been installed and is working satisfactorily.—*Consular Report*.

Stoping Drills at Sudbury, Ontario

By ALBERT E. HALL

*A stoper is cheaper to operate, since it can be handled by one man instead of two, as required on a large machine. In some cases a helper is assigned to two or three stopers, but as a rule this is not advisable. In addition, the use of stopers permits a larger proportion of the total time to be spent in actual drilling. With a big drill, much time is consumed in setting up after a blast or after moving to a new working place; with a stoper, on the other hand, the preparations for drilling are simple. As a rule, a stoper can be rigged up and set to work 30 to 40 minutes earlier than a big drill. One disadvantage of the stoper, when used for shrinkage stoping, is its tendency to create a large amount of shattered and partly loosened rock on the roof and walls of the working place. The men must first scale off this loose ground, which takes from 30 minutes to an hour. With a sufficient number of working places, however, this scaling can be done by a special gang, while the machine men are drilling in a previously sealed place.

As a result of the extra time applicable to drilling, and also of the more rapid drilling, stopers make an average of 30 to 40 linear feet of hole per shift, while a large drill will make 20 to 30 ft. As a rule, stopers work on a bench in the back. When necessary, a bench is created by taking out a diamond cut, and is then followed across the stope. The holes are made about 6 ft. deep. The amount of powder used (40% dynamite) as computed from several groups of holes, averages 0.63 lb. per cubic yard of ore. The amount of air consumed by a stoper is estimated to be about two-thirds of that used by the largest drills.

Some workmen object to the stopers on the ground that stoppages for small repairs are too frequent. It is true that the dust, which is a disadvantage in itself, from the runner's standpoint, sometimes clogs the valve and prevents the extension leg or standard from working properly, but only a few minutes are needed to clean out the valve, and if a screen or a bit of waste be put into the hose, this trouble is almost eliminated. Water sprays can also be used. On the basis of total repair bills, the stopers do not compare unfavorably with the larger machines.

In many places it is impracticable to use a stoper, and a big drill becomes necessary; for example, in hard rock, where the light drill makes little or no headway; but in shrinkage stoping the smaller machine does excellent work. The stoper has one advantage which is probably realized fully only by the men working underground: this relates to the matter of block-holding. Where the muck is being drawn off through chutes, the size must be fairly small so as not to block the chute and so hinder tramming and hoisting. With small stoping drills, the ground is generally broken small enough to pass readily through chutes, and very little block-holing is required. With large machines, on the other hand, considerable block-holing is necessary.

*From Columbia School of Mines Quarterly.

Periodicity of the Stock Market

About the most dependable movement of stocks annually is the advance of prices which almost invariably takes place around and after the middle of the year. It is commonly called the August rise, although a part or all of that month is not always included in the advance and may be regarded as a tribute of appreciation paid to the fact that crops are growing whether the promise be altogether satisfactory or not. In years of financial derangement or deficient harvests, or when politics is unsettling, the movement referred to has often been succeeded by a greater or less decline. In the years which are commonly spoken of as normal, the years such as it is usually our happy lot to enjoy, stocks are likely to go to still higher levels after the August upturn. The interesting fact of it all is, however, the regularity with which the August up-swing occurs. The following table, which is based on a well known set of statistical averages, shows the advances in the periods denoted since the beginning of the present century:

1900.....	June 23 to Aug. 15.....	5.20
1901.....	Aug. 5 to Aug. 26.....	5.81
1902.....	June 24 to July 27.....	5.53
1903.....	Aug. 8 to Aug. 18.....	7.32
1904.....	May 17 to Dec. 3.....	25.85
1905.....	May 22 to Aug. 25.....	9.56
1906.....	July 10 to Sept. 30.....	13.32
1907.....	Aug. 21 to Sept. 15.....	5.37
1908.....	June 22 to Aug. 10.....	12.43
1909.....	June 21 to Aug. 14.....	10.07
1910.....	July 26 to Aug. 17.....	8.84
1911.....	(No advance of any consequence.)	
1912.....	July 12 to Sept. 30.....	6.45

In twelve years out of the last thirteen, this movement has made its customary appearance. It has, of course, been affected by various circumstances antecedent or concurrent. In 1907 it was nothing more than a temporary rebound induced by chronological influences, and in 1904 the prolonged and sustained character of the advance was owing to the protracted liquidation which began in 1903 and carried over to the next spring, when stocks were almost as low as they were in the panic three years later. The average of all the August advances noted in the thirteen years analyzed is almost 9 points.

Now there may not be anything very prophetic in this, but it has a certain application to the course of the stock market since decline terminated on June 10 last. From the low average reached on that day to the high level achieved toward the end of last month, the recovery amounted to about 7¾ points. It can accordingly be said that stocks have already accomplished something like the average of rise which was to be expected around this season. One is not surprised, keeping in mind the customary tendencies of the stock market after the mid-year, to find that there has been this recovery. On the other hand, it would probably not be reasonable to look upon the recovery as necessarily significant of the further course of prices. As in other years, that will depend on developments in politics and finance and on the fortunes of the crops. So far as concerns values, the riddle of the future is yet to be read.—*New York Sun.*

The An-Chi Ironfield

By C. Y. WANG

The ironfield of the An-ehi district, Fukien province, China, is about 60 miles from the coast and outcrops over an area about 17 miles square. There are several localities in which iron ore is found, but I only had time enough to visit one of these localities, named Pun-tien, about 27 miles northwest of Hu-tao. The ore consists of hematite and magnetite and was probably formed through processes similar to those which yielded the deposits of the Lake Superior region. The structural relationship is thus diagrammatically represented:

A rough measurement of the deposit gives 2000 ft. long, 1000 ft. wide, and 500 ft. high. This corresponds to 100,000,000 tons of ore, as a rough estimate. In C there are found pieces of ore that show the quartz grains very distinctly. The following shows the analysis of the ore:

	SiO ₂	Mn	Fe	S	P
Sample 1	0.71	2.40	66.13	0.117	0.009
Sample 2	0.43	0.74	70.95	0.076	0.005
Sample 3	0.96	2.86	66.02	0.088	0.005
Sample 4	0.66	0.72	68.43	0.058	0.010

Wages on the Rand

The *South African Mining Journal* of July 5 published an interesting table of wages paid to white employees at the mines and mills on the Rand, which are as follows:

Machine stopping:	Per day.	Machine-shop, etc:	Per day.
Contract	\$6.88	Foremen fitters	\$5.94
Day's pay	5.34	Fitters	4.84
Hand stopping:		Machinists	4.92
Contract	6.46	Ropes and riggers...	4.92
Day's pay	4.64	Boilersmiths	4.84
Machine development:		Plumbers	4.84
Contract	8.48	Blacksmiths	4.84
Day's pay	4.84	Drill sharpeners:	
Hand development:		Contract	6.36
Contract	6.60	Day's pay	4.95
Day's pay	4.56	Carpenters	4.80
Shaft sinking:		Masons and bricklayers	4.84
Contract	12.10	Engineers:	
Day's pay	6.00	Hoists	5.14
Other miners	3.18	Stationary engines..	4.68
Other underground employees:		Air-compressors	4.50
Shift bosses	6.04	Locomotives	4.80
Timbermen	5.00	Mills:	
Pipemen	4.72	Foreman	5.44
Fitters	4.80	Amalgamators	4.40
Plate-layers	4.46	do assistants.....	3.22
Drill-packer and carriers	3.14	Tube-mill men.....	3.40
Bankmen	3.50	Millwrights	4.96
Skipmen	3.78	Fitters	4.90
Trammers	3.36	Cyanide foremen....	5.40
Pumpmen	4.50	Cyaniders	4.02
Engineers on hoists.	4.90	Slime plant	3.48
		Tank-men	2.80
		Fitters	4.84

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Working Costs at the Standard Consolidated

The Editor:

Sir—I have read with interest the article by C. E. Grunsky, Jr., in the issue of May 31, on the cost of working thin veins in the Standard Consolidated mine at Bodie, California. I have in my note-books some hitherto unpublished figures giving working costs, etc., at the same property, taken from the annual report for the year ended January 31, 1906. This report was never printed, as the documents were all destroyed in the San Francisco fire. The figures herewith were taken from it before the report was sent down to San Francisco from Bodie.

STOPING COSTS

Vein.	Average width, in.	Cost per ton.
Bullion	14	\$ 2.760
Bechtel	20	2.567
East vein, Bullion tunnel	24	1.732
Alpha	30	1.560
West ledge (spotty ore).....	12	6.321
East vein	30	1.851
Fiat ledge	10	1.964
New vein	40	3.444
East Graham	2½	7.620
Bruce (old fills).....	..	12.834
Incline	12	6.062
East vein	3	10.246
San Antone	12	3.217
Hobart	4	11.256
South vein	irregular	9.006

DEVELOPMENT COSTS

	Total per foot.
Driving	\$4.378
Cross-cutting	5.155
Raising	3.655
Sinking shallow winzes varied from \$5.55 to \$8.75.	
Cleaning out old filled drifts	1.746
Cleaning out old filled cross-cuts	1.435
Average cost per foot of development:	
Labor	\$2.802
Supplies	1.114
Total	\$3.916

It will be seen that the average cost per foot of development work has been brought low by the footage of old drifts and cross-cuts cleaned out, which were charged against this account.

It was found profitable to work over the filling in some of the old bonanza stopes, and when this was done the coarse waste was sorted out and all the fine material sent to the mill for ore. The foot-wall hitches were all carefully cleaned out and the foot-wall swept down with brooms. The metal in the old fills came from what the miners had carelessly left on the foot-wall and in the foot-wall hitches in the bonanza days. The stuff that was finally sent to the mill from some of these old fills sometimes ran as high as \$50 to \$60 per ton. In a number of veins it was found profitable to go through the old bonanza stopes and seale off a few

inches from the hanging and foot-walls to get the metal that had impregnated the wall rock outside of the veins.

No less than 120 veins and separate stringers have been mined in the Standard property. It will be realized what a 'honeycomb' the property now is, as many of these veins were only a few feet apart. The ground was rather soft, but it stood well, as otherwise a great deal of the work that has been done would not have been possible.

During 1905 there was 12,141 tons of waste hoisted, 18,542 tons of ore mined, and 18,521.5 tons milled. Of this, 4056 tons of ore was produced from development work. In the same period eighteen sets of timber were replaced in the Standard shaft, which has three compartments, at a total cost of \$1287.47.

ALL COSTS

	Per ton.
Mining:	
General labor	\$2.081
Development (labor and supplies).....	1.246
Stoping (labor and supplies).....	2.170
Distributed costs	0.583
Milling:	
Labor	0.625
Supplies	0.314
Distributed costs	0.466
Bullion charges	0.106
Cyaniding:	
Total, including redemption of capital.....	4.167
Total	\$11.761

In the mill the following battery supplies were used to crush and amalgamate 18,521.5 tons of ore: 65 hammered shoes, weighing 11,180 lb. 81 hard white iron dies, weighing 10,953 lb. 14 front mortar liners, weighing 784 lb. 15 back mortar liners, weighing 1635 lb. 25 end mortar liners, weighing 475 lb. 10 stems were broken during the year. 237 30-mesh punched tin screens were used, and 8346 oz. of quicksilver.

From the beginning of operations with the Moore process plant, stamping was done in weak cyanide solution, in order to save dewatering the mill pulp. It was hard on the copper plates, but was the cheapest thing to do.

It will be noticed that the cyaniding costs were high. This was largely because the period covered was the one in which the original Moore process plant started operations, and the costs include expenditures on account of the various troubles incident to starting up a new plant, in which some of the machinery was especially designed for the work and built out of local scrap.

The original installation of the filter plant was modeled after the original Moore plant at the Mercur mill in Utah, and was one of the first movable-leaf filter plants that was a commercial success. Mr. Dorr had this plant in operation at the Lundberg, Dorr & Wilson mill in South Dakota a few months before the Standard Consolidated plant was ready to run. The Standard plant cost about \$65,000 and the cyaniding cost, as given, includes amortization charges for a five-year redemption period at 5 per cent.

The most satisfactory period of Moore plant operations during 1905 was that of August, September, and October, and the cost per ton treated for these three months was \$2.349, divided as follows:

General expense, including distributed costs.....	\$1.220
Regrinding	0.572
Agitating and filtering	0.314
Precipitation	0.261
Total	\$2.349

Some idea of the troubles experienced in starting this plant may be gathered from the following:

A 5 by 22-ft. tube-mill was furnished us with 1¼-in. smooth white cast iron liners which I was assured would last us six months. They were kept in place in the tube-mill by arching only, and were not bolted to the shell. After about two weeks of running, a heavy load came suddenly on the motor running the whole plant. I opened up the tube-mill and found that all the lining had dropped out and that the plates were practically worn through. No other lining had then been ordered, so as a makeshift I took 6 by 8-in. white pine timbers and sawed them into blocks about 6 in. long and made a lining of these blocks set endwise. A number of such lining were used up, as they lasted only about two weeks. I also tried one set of mountain mahogany, a hard wood which was gathered at considerable expense in the high Sierras, thinking this would be better and last longer; but this was a disappointment. As there was a lot of old machinery around Bodie, Cornish pump-rod straps, which were 6 and 8 in. wide by 1 in. thick, were tain mahogany, a hard wood which was gathered at stalling them lengthwise so that the inner section of the tube-mill was a polygon. The straps were bolted to the shell, and leakage was prevented at the bolts by putting under the washers what our millwright assured us was a 'gommet.' These linings did excellently well and were still in use when I left the Standard in 1906.

During the periods that the tube-mill was shut down I sent the stamp-mill pulp straight through to the filter vats, in which were installed agitators. It was not long before the coarser sand had cut out the bottoms of our filter leaves, which did not add anything to our gaiety, and, as A. D. Foote has well said, "we learned, slowly, something more."

The cost of operating the power-plant, which generated from 350 to 400 hp., for the year was \$8582.62. Of this, the labor amounted to about \$4200. The rate of pay for all labor was the same in 1905 as that given by Mr. Grunsky.

EDWARD H. NUTTER.

San Francisco, July 25.

Nevada Metal Output

The total value of the mine output of gold, silver, copper, lead, and zinc in Nevada in 1912, according to V. C. Heikes, of the United States Geological Survey, was \$38,358,732, against \$33,952,529 in 1911, showing an increase of \$4,406,203, or nearly 13 per cent.

The total production of gold in 1912 was 650,942.70 oz., valued at \$13,456,180, a decrease of \$4,737,217, or 35% less than the 1911 production. Of the gold output, 11,206.21 oz. came from placers (mainly in Nye county), 608,132.85 oz. from silicious ores, 23,511.61 oz. from copper ores, and 8092.03

oz. from lead, zinc, and copper-lead ores. Silicious ores yielded over 93% of the entire gold production. From bullion in gold and silver mills was recovered 533,611.94 oz., concentrate produced 63,344.08 oz., and crude ore shipped to smelters contained 36,996.68 oz. The largest production of gold was from Esmeralda county, which was \$7,014,559 in 1912, against \$11,198,602 in 1911. Of this production the Goldfield district yielded \$6,239,747, a decrease of \$4,047,328, or over 39%, from the output of 1911. Nye county produced \$3,123,935 in gold in 1912, against \$3,617,276 in 1911. The Tonopah mines yielded \$2,223,878 in gold, a decrease of \$142,617, or over 6% less than in 1911. The Comstock mines produced \$855,494 in gold, against \$977,349 in 1911.

The silver production of Nevada in 1912 was 14,369,063 oz., valued at \$8,836,974, against 13,184,601 oz., valued at \$6,987,839, in 1911. Of the 1912 output, 13,135,677 oz., or over 91%, came from silicious ores, 841,733 oz. from lead ores, and 173,545 oz. from copper ores. Bullion at gold and silver mills produced 10,002,279 oz., concentrate 2,301,694 oz., and crude ore sent to smelters contained 1,546,220 oz. Nye county produced 10,210,296 oz. of silver in 1912, against 10,918,263 oz. in 1911. Of this output the Tonopah district yielded 10,144,987 oz., or 70.6% of the entire silver production of Nevada in 1912. Storey county (Comstock) produced 806,853 oz., against 618,006 oz. in 1911.

Copper production increased in Nevada from 67,377,518 lb., valued at \$8,422,190, in 1911 to 86,477,494 lb., valued at \$14,268,787, in 1912. This increase was due to the operation of the Mason Valley plant, which smelted ores from the Yerington district and other mining districts in Nevada. This smelter and the Steptoe plant in White Pine county produced, from the treatment of ores and concentrates, 83,389,088 lb., of 96.4% of the entire state production. Concentrates yielded 64,979,228 lb. of copper, and crude ore sent to smelters 21,423,801 pounds.

The production of lead in Nevada in 1912 was 19,500,100 lb., valued at \$877,505, against 3,263,657 lb., valued at \$146,865, in 1911, an increase in quantity of about 497%. The mines of Lincoln and Clark counties, the largest producers, yielded 17,315,250 lb., an increase of 15,230,189 lb. over the 1911 production. The mines of Eureka county produced 230,710 lb. in 1912 and 61,136 lb. in 1911. This increase is accounted for by the operation of the railroad which was washed out in 1910. Crude ore shipped to smelters contained 6,558,003 lb. of lead, concentrates 5,913,188 lb., and old tailing 7,028,909 pounds.

The zinc production of Nevada was 13,322,988 lb., valued at \$919,286, in 1912, against 3,548,032 lb., valued at \$202,238, in 1911. The entire production of 1912 was derived from Clark and Lincoln counties from ores shipped to smelters containing 4,669,816 lb. and from concentrates containing 8,653,172 pounds.

There were 702 producers of gold, silver, copper, lead, and zinc in Nevada in 1912, compared with 661 in 1911. The total quantity of ore sold or treated in Nevada in 1912 was 4,763,965 short tons.

Special Correspondence

MELBOURNE, AUSTRALIA

FUTURE OF AUSTRALIAN MINING.—A SILVER-LEAD-NICKEL-TIN PROSPECT.—TIN-LEASE APPLICATION.—MOUNT CARRINGTON.

Before bidding farewell to Australia, W. J. Loring, one of the partners in the firm of Bewick, Moreing & Co., mining engineers, who is now on his way to England, gave in newspaper interviews his opinion upon the state of mining in the island continent. With an eye to the improved methods of treating lead, zinc, and copper-bearing ores, he looks for great development in the mining industry. He emphasized the fact that the Broken Hill was no longer to be looked upon as merely a silver and lead field, and that of those metals extraction was much higher than used to be the case. It is not surprising, in view of his firm's connection with the Company, that he illustrated his argument by the operations of the Zinc Corporation. Only seven years ago, he said, an extraction of 72% of the lead and 55% of the silver was considered remarkably good. Now the recovery is up to 85.3% lead and 68.6% silver, and an extra 2.3% lead is obtained from the treatment of the zinc middling, the total lead recovery constituting a world's record on this class of metal.

Some attention is being directed to the purpose of the Great Zeehan Dundas Silver Lead Mining Co., N. L. The Company holds an area of 33 acres near the town of Zeehan, near the west coast of Tasmania. Though it is called a silver-lead mining company, its purposes are not confined to these two metals, but extend also to nickel and tin. There are running through the property three lodes which are being prospected by another company whose property adjoins on the south. One of the lodes contains copper and has not as yet been properly opened; one is a pyritic lode 10 ft. wide on the surface, and another contains galena, on which most of the work done has been concentrated. A fourth lode, previously unknown, has lately been opened, and this, where cut in the adit driven into the hill to cross-cut the other three lodes, averages 63% lead, 7% copper, and 50 oz. silver per ton. This was narrow at first, but has since widened to 4 ft., 25% of it consisting of solid metal and the balance of good second-class ore. Still later, in the southwest portion of the Company's property, a promising lode has been discovered. It occurs in a large ironstone formation, is 20 ft. wide, and assays 3.5% tin, according to the mine manager, who states that the formation extends into the highest part of the range, and, so as to include all possible extensions, he staked another claim for the Company. It may be worth while to quote his words: "Here the ironstone outcrops in immense boulders and appears to be chains wide; in fact, the mountain appears to be one mass of iron, which stands out boldly from the surrounding country, and is about 900 to 1000 ft. above the point where I first found the formation, and distant about 60 chains. If we get the same metal values in the ore in the mountain as we got in south section, this will stand equal to Mt. Bischoff, as we have the quantity, and now we have to prove the metal content." There is a peculiar tone about this which is not quite convincing; but, in spite of that fact, it seems probable that something fairly big and good has been found. It is to be hoped so, for the sake of Tasmanian mining, which has not been so flourishing of late.

The Ardlethan tin boom has meant a good thing for the Mines Department of New South Wales. During the year ended June 30, no less than 1200 applications for titles on the field were received. In view of the fact, it is not surprising that the Department's revenue during the year amounted to over \$658,000, nearly \$73,000 in excess of the previous best year on record, and some \$276,000 in excess of the expenditure. Unless another boom starts, the receipts for the current year are bound to show a great shrinkage.

Undeterred by the failure, none the less marked because unacknowledged, of the Victorian State coal mine, the New South Wales Minister for Mines is said to have the in-

tention of putting on the state's estimate of expenditure a sum of several thousand pounds for the establishment of a state coal mine in this state. The public does not look forward to the outcome with confidence, but, after all, there is a considerable distance between the intention to do this and the actual business of putting the money down. Nor is it too certain that the present New South Wales government will continue to hold office.

F. B. Powell, a well known mining engineer, has reported upon the Mount Carrington, a copper mine near Tenterfield, New South Wales. In his opinion, the adit which was driven into the hill on which the mine is situated was disappointing in its results, because it was driven on the hanging wall of the Pioneer lode and left the lode standing. He thinks that, this being so, there is from 200 to 250 ft. of backs immediately available for development at a low cost. As to the Company's other main lode, the Carrington, he recommends the testing of the ore by the Minerals Separation flotation or Murex magnetic process, either of which he thinks should produce a high-grade concentrate. On the whole, Mr. Powell considers the mine more than an ordinary good mining gamble.

JOHANNESBURG, TRANSVAAL

OPERATIONS OF THE GOERZ GROUP.—PRESENT CONDITION AND FUTURE OF THE MINES CONTROLLED.

Although the Goerz group of mines is the most insignificant as regards scale of operations among the mining groups on the Rand, still the individual mines controlled by that group possess today several features of more than ordinary interest. At the recent annual meeting of shareholders here, the chairman of directors drew attention to several interesting features because the mines controlled by this particular group are scattered more or less over the whole length of the Rand. It is probable, however, that in the Geduld Proprietary Mines and the Modderfontein Deep, on the Far East Rand, the group controls mines of greater potential value than all the rest of the mines under their control. Nevertheless, for many years the Geduld Proprietary Mines were under a cloud and it was only during the last twelve months that these mines began to show an improvement. During 1912 the profitable ore reserves increased in amount from 736,000 to 1,475,000 tons, and in assay-value practically 24c. per ton. Meanwhile, the capacity of the reduction plant has been increased to 24,000 tons per month, which nevertheless is a tonnage far below the capabilities and requirements of the property if an adequate return is to be obtained on its large nominal capital. This Company has an issued capital of \$3,700,000—a capital not too large for the size of the property—but operations hitherto have been conducted on such a limited scale that the shareholders, after ten years' weary waiting, have not been sufficiently fortunate to be rewarded with a dividend. The other property on the Far East Rand belonging to this group, which has come to the front during the year, is the Modderfontein Deep, where the main 'reef' was intersected at a depth of 3000 ft., which, on being driven on to the extent of nearly 8000 ft., assays \$7.60 per ton over a width of 48.6 in. This property is regarded as one of the most promising on this part of the Rand; so much so that the May Consolidated Co., whose mine near Germiston is fast approaching exhaustion, is acquiring a large interest in the Modderfontein Deep property. The Van Dyk Proprietary Mines, also on the Far East Rand, however, remain closed, owing to want of capital, with but little prospect of being reopened.

With regard to the interests held by the Goerz group on the Western Rand, the year just closed has been a disappointing one. To the previous serious losses already incurred by this group, have now to be added those at the Lancaster mine, which was unfortunately closed during the year owing to the losses and unsatisfactory manner in which the property developed. Another disappointing mine on the Western Rand belonging to this group was the Princess Estate, where, despite its reconstruction and absorption of neighboring properties, the results attained during the year were anything but satisfactory.

The prospects of both the Lancaster West and Princess Estate are at present somewhat uncertain, while the Tudor, Randfontein Deep, and other properties belonging to the same group in the Western Rand are still closed, and in an undeveloped condition. The Goerz group, however, is interested in mining properties not only in German West Africa, but also in Mexico.

DEADWOOD, SOUTH DAKOTA

HISTORY, MINE DEVELOPMENT, AND PROGRESS IN CYANIDATION AT THE PROPERTY OF LUNDBERG, DORR & WILSON, NOW SHUT DOWN.

The property of Lundberg, Dorr & Wilson, which has recently been closed, is situated on both sides of Fantail gulch, just below the town of Terry, Black Hills district, South Dakota, and the following notes should be of interest.

It consists of the Buxton mine, on the north side of the gulch, with workings extending through the hill about 800 ft., to Nevada gulch, and the Bonanza mine just across the gulch on the south side. The mill is on the Buxton side and ore from that mine is trammed directly into the ore-bins. The Bonanza ore was delivered at the top of the mill by a Bleichert jig-back tram with buckets of 1200 lb. capacity. There is only a single span of 910 ft. The tramway has a capacity of 15 tons per hour and is operated by one man at the loading station.

The mines were opened in the early eighties, and as no recovery could be made by amalgamation or concentration, the first ore produced was shipped to Omaha, partly by wagon haul, with a freight and treatment charge of \$40 per ton. A smelter at Deadwood, started in 1892, reduced the charges to \$16 at first and finally to \$8 per ton. After producing something over \$1,000,000 gross, the Buxton Mining Co., owning the property, stopped operations and turned the property over to lessees. Later it was sold for a nominal sum, as entirely stripped of ore that could be profitably handled. The new owner leased it to John Lundberg, and during that period the ore mined was treated at a custom cyanide plant operated by Lundberg & Dorr at Deadwood for nearly two years. About ten years later the above firm enlarged to Lundberg, Dorr & Wilson, and bought the property, figuring that there was a large amount of \$4 to \$6 ore left in it which could be made to yield a profit with a modern mill on the property. The mill and tramway were begun in July 1903 and commenced operations in January 1904. Since then the property has continued steadily in operation, with the exception of two shut-downs during the eight-hour and closed-shop general strikes in 1907 and 1910, until it closed down at the end of July 1913 on account of the exhaustion of its ore supply. Its estimated capacity of 75 tons per day was gradually increased to 110 tons, and both mining and milling costs were reduced until ore as low as \$3 was profitably handled.

The mill is of interest historically as having passed through the whole period of modern American cyanide practice. When designed, leaching was the standard practice. Slime was the *bête noir* of the millmen, both on account of the difficulty of separation from sand and the recognized losses in decantation, the only method of treatment in use in this country. The apparent necessity of holding all the mill tailing on the side of the gulch, as well as the efficiency indicated, led the firm to install the Moore process, then being tried at Mercur, and this gave it the distinction of operating the first leaf-filter plant to remain in successful operation for any length of time. The difficulties encountered in sand and slime separation by hydraulic cones were overcome by the invention of the Dorr classifier in July 1904, and from this mill its use and that of other mechanical classifiers has spread over the whole country and into most cyaniding districts in the world. With the very slimy ore handled at this plant, the machine was responsible for its success. Of local interest perhaps is the fact that it was the pioneer in the Black Hills in the use of electric power purchased from a central plant, and in the use of Chilean mills for fine crushing, and belt elevators for handling pulp crushed

in cyanide solution. The total tonnage milled was approximately 285,000 tons, of which about 60% came from the Company's mines and the other from custom ore. Owing to its operation as a custom plant, no figures on operating costs or extractions have been published.

The total production has approximated \$1,500,000. As the ownership of the property is a partnership, the earnings are not of general interest beyond the fact that the net profits after deducting the cost of the property and all improvements have been several times as great as the estimate made when the property was bought, although the actual value of the ore has been less than estimated. One reason for the success of the property has been the indefatigable energy and care bestowed upon it by J. M. Pennington, Jr., the manager. Mr. Pennington came with the firm as assayer at the beginning of operations, and gradually assuming more responsibilities, ended as manager when the plant was closed. Many of the men employed in the mines and mill, including the shiftmen, were with the firm nearly the whole time of operations, and by their faithful and intelligent service contributed materially to the success of the operations.

NEW YORK

EFFECT OF ELECTRICAL WORKERS' STRIKE AT BUTTE.—MIAMI SMELTING CONTRACT WITH GREENE CANANEA.—BRADEN COPPER.—QUICKSILVER MINING COMPANY.

The strike at Butte is probably more serious in its possibilities than has been generally recognized. The electrical workers in the employ of the Montana Power Co. constitute the storm centre of the disturbance so far, and their demands up to the present point have been met with a decided refusal. The Montana Power Co. supplies electric current for most of the mines and smelters in the Butte district, and in the event of a real test of strength these workers are in a peculiarly strong position so far as enforcing a shut-down is concerned. In addition to calling upon the miners to go out in sympathy with them, the cutting off of electric power would in a short time cause most of the mines to be seriously crippled, if nothing more. The directing head of the Montana Power Co. is John D. Ryan, who is now on his way from New York to Butte, to take charge of the situation in person. Butte has been the scene of some of Mr. Ryan's greatest achievements as a peacemaker, and it is quite safe to say that the interests or the respective rights and duties of the contending parties could not be in safer hands. No small part of the career of Mr. Ryan has been spent in bringing peace out of strife, in the earlier days in Butte, later in the work of getting the copper producers together, and securing and maintaining some degree of equilibrium for the copper metal market. Mr. Ryan's experience rather qualifies him to adjust almost anything except an 'irrepressible conflict,' and he would probably be equal to getting a long postponement in such a case.

The Miami Copper Co. has made a new 10-year smelting contract with the Greene Cananea on a basis understood to be distinctly more favorable to the Miami than the contract just terminated. The concentrate from the Miami mill is sent into Mexico in bond, and the smelter product is shipped for refining to the International Smelting & Refining Co.'s plant, at Raritan, New Jersey. The Miami, however, sells its own production, handling also that of the Shattuck-Arizona, which, like the Miami, ships its ore to Cananea and the product to Raritan.

Operations at the Braden Copper Co., Chile, have been interrupted by a storm, which necessitated repairs to the transportation equipment of the plant and forced a shut-down of the mill for the last 10 days of July. Production totaled 1,046,000 lb. Not all of the treatment problems at the Braden have been solved yet, but while results are not up to expectations so far, there is nothing but will be overcome in time and production brought up to approximately the estimated figures.

The Quicksilver Mining Co., which has recently had a hard time financially, has succeeded in making sale of a note issue of \$25,000, and the management states that a receivership will be unnecessary.

MOGOLLON, NEW MEXICO

DEVELOPMENT AND MILL WORK OF THE ERNESTINE, SOCORRO, DEADWOOD, PACIFIC, OAKS, MAUD, AND LINCOLN MINING COMPANIES DETAILED.

A contract was recently let for sinking the main shaft of the Ernestine Mining Co. Considerable water was encountered, necessitating the installation of a pump. A large amount of other development is adding to the already large ore reserves. The mill is treating 150 tons per day with 30 stamps, and 10 stamps are in reserve for emergencies. The new oil-engines installed several months ago are giving satisfaction, and the Company now has a surplus of power.

Two additional oil-engines of the De la Vergne type were also installed by the Socorro Mining & Milling Co. recently. A proposal to light the business houses of Mogollon with electricity is being discussed by the Company. Some of the best grade ore is coming from the 800 and 900-ft. levels. The mill is treating about 175 tons per day. In July over two tons of gold and silver bullion and

of the district at depths of from 1400 to 1800 ft., is advancing steadily. In the east end tunnel group, adit 'A' has been driven 300 ft., and a contract was recently let for sinking a winze. Work is also going on in the adits 'B' and 'C.' Ore from these workings is shipped regularly to the custom mill.

The new shaft of the Maud Mining Co. has reached a depth of 485 ft. and has been in good ore a greater part of the distance. The Company is sending 10 tons per day to one of the custom mills, all coming from shaft development.

The Lincoln Mining & Development Co., successor to the Enterprise Mining Co., is preparing to do extensive development work, chief of which will be sinking the shaft, which reached water-level some time ago, when work had to be discontinued on account of the excessive inflow. A pump will be installed. It is rumored that the mill will be altered to accommodate custom ore that is available from a number of properties developing in the north side of this district.

CANANEA, MEXICO

MINING OPERATIONS OF THE EASTERN CANANEA DEVELOPMENT, CALUMET & SONORA, MOCTEZUMA COPPER, MEXICAN METALS COMPANIES.—NEW EQUIPMENT AT VARIOUS PROPERTIES.

The Eastern Cananea Development Co. has resumed development at the Cananea-Eastern mine, situated about 18 miles east of Cananea. There are about ten men employed at present, the number to be increased as soon as possible; John Martin is in charge of the work. Operations were stopped about six months ago, and at that time the drift had entered an orebody of considerable value, about 20 ft. of the ore having been opened averaging 10% copper.

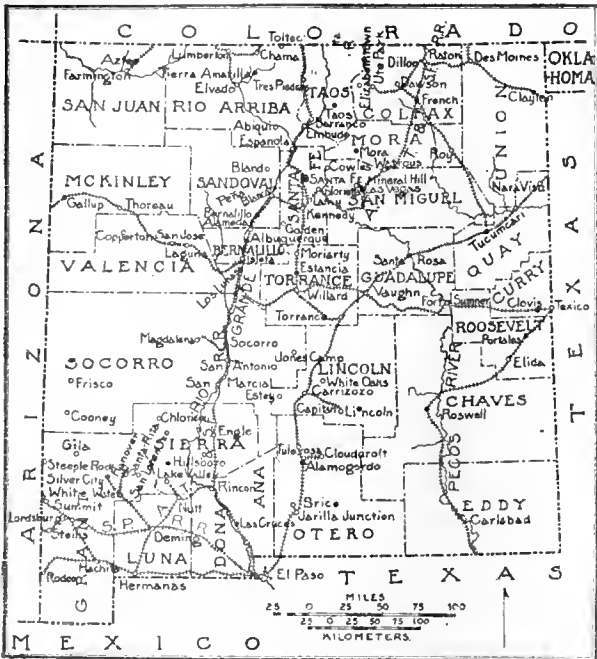

The Calumet & Sonora has stopped mining operations for the present and the only work done underground is raising ore which has been previously broken. There is sufficient ore broken to supply the mills for five or six weeks. The Company is planning to resume sinking soon, from the 525-ft. level to about 750 ft. The increased depth will undoubtedly be of great value to the property, as with every foot that has been sunk the copper content of the ore has increased, while the silver, zinc, and lead have decreased. The property will eventually prove a copper mine of considerable worth. The property will soon be examined by a prominent mining engineer for a number of large stockholders in the Company.

The Pilares, Guadalupe, and Esperanza shafts of the Moctezuma Copper Co., at Nacozari, are to be sunk from the 1000 to the 1500-ft. level, at which point all will be connected by drifts. Last year the shafts were sunk from the 750 to the 1000-ft. level. Development between the 750 and 1000-ft. levels has proved to be satisfactory, as the grade of ore is higher than that on the levels above.

Harold Wheaton, of Nogales, manager for the Mexican Northern Mining Co., has taken over El Plomo mine near Sasabe, in the Altar district, which he recently purchased from Fred S. James of Chicago. There are twenty men employed at present.

There has been a high-grade orebody opened at the Copete property of the Copete Consolidated Mining Co., which is situated near Carbo. The ore runs high in glance and native copper and contains several ounces in gold. The orebody already exposed is estimated at 150 to 225 feet.

The Mexican Metals Co. (Moctezuma-Arizpe Development Co.) has received a carload of new machinery, which was freighted to the property, 18 miles from Cananea, during the past week, and is now being installed. The shipment included an Ingersoll-Rand compressor of 1400-cu. ft. capacity, and a Bessemer twin cylinder 165-hp. oil engine. A second Bessemer engine of the same capacity will be installed later, it already having been shipped. With the new machinery installed, the Company will have an up-to-date and complete plant, and it will enable the Company to increase its production considerably. Concentrate netting \$54 per ton is being shipped to the El Paso smelter regularly. Shipments average about a carload per week, and this will

MAP OF NEW MEXICO.

a large amount of high-grade concentrate was shipped, breaking all previous records.

A new orebody has been cut by the different levels south of the main shaft of the Deadwood mines toward the Sunburst mine, one of this Company's properties. The mill is treating from 350 to 400 tons of ore per week, and 600 lb. of gold and silver bullion and 1500 lb. of concentrate were shipped from last clean-up. A considerable tonnage of custom ore is sent in from developing companies.

A large amount of machinery for development work is on the ground for immediate installation by the Pacific Mines Co., including a compressor, machine drills, crusher, motors and transformers, and electric hoist. Current work will be furnished by one of the local companies. The main adit is now in 900 ft., and the new shaft has reached a depth of 240 ft. Drifts are being driven on No. 2 and 3 levels. The vein is 5 to 8 ft. wide and assays from \$15 to \$18 per ton. All ore taken out in development is sent to one of the local custom mills; 120 tons being shipped the week ended August 9.

The C. H. Putnam Engineering Co., of Los Angeles, has been operating the Little Charlie mine, one of the Mogollon Gold & Copper Co.'s properties, under bond and lease, for over a year, during which time several thousand tons of excellent ore has been mined, part of which was shipped direct to smelter and the rest to local custom works. A 25 to 30-hp. crude-oil engine and electric hoist have been installed. From 20 to 30 tons of ore is shipped daily.

The main drainage and transportation tunnel of the Oaks Co. on Mineral creek, which will cut the orebodies

be about doubled when the additions to the power-house are completed. The Company is using a Pierce-Arrow 6-ton auto-truck to freight its supplies from Cananea to the property and concentrate to the railroad, and during the recent heavy rains, which made the roads almost impassable, the truck has been doing excellent service. It is predicted that the August production of the Cananea Consolidated Copper Co.'s smelter will total close to 7,500,000 lb. of copper gross. Four furnaces, besides two reverberatories, are in operation.

The latter part of the month will see the 75-ton smelter of the Chicago Exploration & Development Co., at Mina, Mexico, 45 miles from Tonichi, blown-in and in operation. It is impossible to get coke, and a large quantity of charcoal has been burned as a substitute. It is said that there is 500 tons of concentrate ready for treatment, which will average 100 oz. silver per ton besides the copper content. W. E. Pomeroy is manager, George Squire smelter superintendent, and Charles Gercken mine superintendent.

TORONTO, CANADA

DIVIDEND RECORD OF COBALT.—THE NORTHERN CUSTOMS MILL CHANGES OWNERSHIP AND WILL BE ENLARGED.—DRAINING KERR LAKE.—THE KIRKLAND LAKE DISTRICT.

A report by A. A. Cole, of the Temiskaming & Northern Ontario Railway Commission, gives the total amount paid in dividends by the Cobalt mining companies up to June 30 at \$46,506,155.

Seven of the companies have redeemed their entire capital obligations. The group of English capitalists operating the Cobalt Townsite, Casey Cobalt, Cobalt Lake, and other mines, have purchased the Northern customs mill and concentrator, the price being stated as \$250,000. It is the largest mill in the district, and has 180 stamps. The purchasers take control on November 1, and will enlarge its capacity by adding 100 stamps. The Northern Customs was the third plant to be built at Cobalt, and has done a profitable business, sufficient funds having been provided from the earnings for its enlargement from time to time, in addition to yielding good returns on the investment.

All arrangements for the draining of Kerr lake by the Crown Reserve and Kerr Lake mining companies for the purpose of developing additional ore reserves are expected to be completed by the end of August. The work will require three months of steady pumping. The overflow will be received into Giroux lake, about half a mile distant, which will be utilized as a reservoir for the supply of the Crown Reserve, Kerr Lake, and Drummond mines.

The Cobalt Lake has declared a dividend of 2½%, being the third declared for the present year. While only interim returns have so far been made, it is understood that henceforth they will be regularly continued on the basis of 10% per year. The financial position of the Wettlaufer of South Lorrain has somewhat improved. The latest report, dated July 11, showed cash on hand to be \$158,631, and silver in transit or at the mine of an estimated value of \$60,000. Ore development has not been satisfactory, and the reserves are approaching exhaustion. Prospecting is being carried on by diamond-drilling and a calcite vein is being opened in the hope of finding new orebodies. The Sterling mine, of Elk Lake, which was recently sold by order of the court for \$300,000, is again on the market, owing to the default of the purchaser in the payment of the deposit required.

Kirkland Lake, for the present at least, has quite eclipsed Porcupine as a centre of mining interest. The Teck-Hughes vein has been cut at the 100-ft. level, about 35 ft. from the shaft, where it shows 14 in. of high-grade ore, equal to that on the surface. The vein had dipped out of the shaft at a depth of 40 ft. A winze will be sunk on the ore to the 200-ft. level. On the Robbins property, adjoining the Foster, a vein two to three inches wide shows visible gold and carries tellurium. It has been stripped for some distance. The Wright-Hargraves claims, on which good discoveries have been made, have been taken over on option by Barr Cartwright and associates, and development will be actively undertaken. The Hudson Bay Mining Co., of Cobalt, has acquired several claims in the district.

BOSTON

COPPER PRODUCTION OF THE MASON VALLEY SMELTER AND AFFAIRS IN THE YERINGTON DISTRICT, NEVADA.—IMPROVEMENTS AT EAST BUTTE.—THE BUTTE, WISDOM & PACIFIC RAILWAY.

The July statement of production from the Mason Valley smelter is a disappointing one, showing that the plant, for the first time since it was blown in at the beginning of 1912, has fallen below a monthly output of 1,000,000 lb. The total for July is only 990,000 lb., as compared with 1,132,000 lb. in June and 1,460,000 lb. in July 1912. The trouble is attributed to the failure of the Nevada-Douglas company to keep shipments of ore up to normal. It is claimed that the smelter receives ore from nearly 150 small shippers from mines in western Nevada and portions of California and Oregon. Notwithstanding these additions to the volume of business, a decrease is shown. The Nevada-Douglas company had a contract when the smelter started to furnish it with 250,000 tons of ore, and is presumably under obligation to complete this contract, so the decline in shipments from Nevada-Douglas must be due to conditions at its own property. The drift of things at Yerington, which was once proclaimed as the biggest copper possibility among the Western districts, indicates that a consolidation will be necessary, as it will be unsatisfactory to Nevada-Douglas and Mason Valley stockholders for conditions to continue this way much longer. Nevada-Douglas paid one dividend of 12½¢. per share, which was generally considered premature, and has since not only failed to announce any more dividends, but a \$2,000,000 bond issue was shortly after authorized. That kind of financing, while conceivably well intended, does not find favor, and there has been much criticism of the financial management. Now that the Company is not keeping up ore shipments, further dissatisfaction is expected. It is stated that the management has engaged in other promotions and prospecting pursuits, while financial and mine conditions apparently suffer. Little Mason Valley stock has been distributed among the public, but Nevada-Douglas probably has over a thousand stock and bond holders who have been given to understand that their money has gone into a mine which would be a large producer and dividend payer. Evidently the best thing that can eventuate in Yerington would be the acquisition of Nevada-Douglas and Bluestone by the Mason Valley interests, which have enlarged their original \$90-ton smelter to a capacity of 2000 tons without increasing the Company's outstanding capital a dollar. The Yerington mine should have liberal and able financing in order that investors may be satisfied as to the productive merits of the district.

It is announced that the improvements at East Butte will be completed by the end of the year. This includes the duplicating of the present smelter capacity, the practical rebuilding of the concentrator, and increase of about 600 tons per day and electrical equipment of the East Butte mine No. 1, and its reopening. The No. 1 mine operations were suspended about six years ago, since which time the property has lain idle. The shaft is down 900 ft. and it is proposed to unwater it and sink deeper. The Pittsmtont property is said to be in good condition. Some criticism is made in Butte of the East Butte statements failing to show the output of the mine itself. The production given is that of the smelter, which receives custom ores from several properties in Butte, the Radersburg district, and others. It has been stated that these monthly figures have been handled in such a way as to give the impression that the amount of ore contributed by East Butte is larger than is evidently the case.

W. R. Allen announces that surveyors and engineers are in the field over the route of the Butte, Wisdom & Pacific railway, and that actual construction work is to be hurried this fall. This road is controlled, through stock ownership, by the Boston & Montana Development Co. It will operate within Silverbow, Deer Lodge, and Beaverhead counties, traversing the richest mining and ranching country in Montana. The road will be extended into the Big Hole basin of Beaverhead county.

General Mining News

ARIZONA

GILA COUNTY

(Special Correspondence.)—At the Copper Hill shaft of the Arizona Commercial, at Globe, considerable exploration work is being planned in the ground below 600 ft., where a raise, recently completed from the 700 to the 600-ft. level, showed the presence of rich chalcopryrite ore, convincing the superintendent, R. R. Boyd, that the ore-body formerly explored on the 600-ft. level extends to greater depth. Considerable low-grade sulphide and abundance of iron has been found on the 1200-ft. level. An electric furnace with a daily capacity of 50 tons is being used at Globe to test Copper Reef ore, of which about 50 tons recently was brought in for the test.

At the Southwestern Miami the casing has been pulled from No. 4 hole, and No. 16, about 250 ft. southwest of No. 15, has been started. The Inspiration Extension shaft is now about 40 ft. deep and the bottom is so thoroughly impregnated with carbonate stains and sulphide stringers as to have the appearance of low-grade ore. The schist being cut by the shaft is identical with the ore-bearing schist of the Inspiration and Live Oak groups, the former of which is adjoined by the Inspiration Extension.

Miami, August 14.

GREENLEE COUNTY

Owing to a draw-bar breaking on an ore-car of the Coronado mine incline, on August 13, nine men were killed

LOOKING DOWN ON METCALF, ARIZONA, FROM TOP OF CORONADO INCLINE.

and others injured. This incline is 3300 ft. long, and is at an angle of 38°, and has been used for fifteen years, but is being displaced by a tunnel, as described in our issue of August 16. Passenger traffic was not permitted as a rule. The safety chains broke when the loaded cars jerked them.

MARICOPA COUNTY

A large quantity of machinery is on its way to the property of the Sunflower Cinnabar Mining Co., 80 miles northeast of Phoenix, in the Mazatzal mountains. The dump at the mine contains 10,000 tons of ore averaging 6% mercury, and the Company expects to produce about 14 flasks per day.

CALIFORNIA

AMADOR COUNTY

The west cross-cut on the 2500-ft. level of the Keystone mine has cut a body of well mineralized quartz. Assay-values are not yet known, but the presence of the vein is encouraging. The superintendent, C. R. Downs, is having the cross-cut run farther west, as he believes that the main fissure has yet to be opened. In all probability it will be necessary to continue west at least 100 ft. These new workings are at a depth of 2500 ft., and 1500 ft. under the lowest level of the old mine.

NEVADA COUNTY

(Special Correspondence.)—At the Grizzly Ridge mine, the installation of 8 electric motors, 3 transformers, and a large duplex air-compressor was recently completed. The equipment, consisting of compressor, mine fans, mine pumps, hoist, rock-crusher, ten 1200-lb. stamps, tables, and machine-shop are electrically driven. Telephones are being installed on all levels from the 300 to 1000-ft. level in the mine. Everything is working at full capacity.

Nevada City, July 14.

PLACER COUNTY

Development work in the Eldorado mining district is increasing. It is understood that the Central Eldorado Mining Co., which is operating the old Davidson mine, is adding 10 stamps to the mill of the same size already in operation.

SHASTA COUNTY

Machine-drills and 21 men are at work in the Balaklala mine breaking ore, and the aerial tramway at the smelter is ready to carry ore. At the smelter, 62 men are busy, and the following work has been done: The gas plant is approaching completion; a new brick smokestack connecting with the McDougall furnaces has been built; tramways have been laid; the rock-crushing plant has been put in order; machinery for the Hall smoke-eliminating plant is on the ground, and much of it is in place. The Field washer, which plays an important part in the elimination of smoke, is at hand, and part of it has been set up. F. M. Leland is general manager, and he hopes to have a trial run in about three weeks.

SISKIYOU COUNTY

(Special Correspondence.)—Reeves Davis is installing apparatus designed to establish an undercurrent in the sluices at his hydraulic property. The device is intended to save the black sand which has hitherto run to waste. This marks the first attempt to save the gold contained in the black sand of this district, as it has been previously considered too poor to warrant saving. The Siskiyou Mines Co. continues to operate on Morgan's Point with a full head of water. Late heavy rains largely increased the water flow, prolonging the season several weeks. Several placer-mining companies are working later than usual as a result of the heavy rains of a month ago. Small shipments of rich ore have recently been made from the Homestake mine, Salmon River district, to Yreka. The shoot is several inches wide and apparently improving in size as work advances. R. S. Taylor, of Yreka, is principal owner. Operations have been suspended at the Sheba mine, which has been a steady producer since 1899. The plant has been dismantled and offered for sale. W. H. Linforth, F. Belden, and other San Francisco people are the owners.

Fort Jones, August 10.

TUOLUMNE COUNTY

(Special Correspondence.)—J. E. Holden and C. L. Manley have assigned their interests in the Chilano mine, near Tuttletown, to the Jamestown Consolidated Mines Co. A force of eight or ten men, with Mr. Manley in charge, is

working at the property. The old shaft, 100 ft. deep, sunk through crossings in the hanging wall long ago by miners who look only for 'pockets,' will be enlarged to three compartments and sunk to at least 300 ft. Drifts will be driven along the hanging wall and cross-cuts to the foot-wall at each 100 ft., and the ore extracted in development will be put through the small mill, which is being thoroughly repaired, to determine the exact value of the ore in every part of the vein. Assays taken in a cross-cut from the hanging wall to a point 20 ft. into the vein average \$3 per ton. According to report, the Shawmut company has purchased the machinery of the Tarantula mine and will remove it from the latter property.

Sonora, August 9.

Rich ore has been opened in the Eagle-Shawmut mine at Shawmut, the shoot being 12 in. wide. It is proposed to sink a shaft from the 400-ft. adit-level.

COLORADO

CLEAR CREEK COUNTY

(Special Correspondence.)—On the Hancock level of the Sunburst mine, Democrat mountain, a streak of ore 5 in. wide has been exposed, valued at 50 oz. silver per ton. The shoot is showing for 15 ft. E. J. Butts is operating under a bond and lease. The Oriental adit on Lincoln mountain has cut the Lucky Gus vein at a distance of 250 ft. from the portal. A body of galena is showing which is 7 in. wide, assaying \$82 per ton in gold, silver, and lead. A. T. Swanson is owner. Work was resumed this week on the World's Fair property in East Argentine. L. Hoery is manager. The Toledo property, on Pendleton mountain, is undergoing development. T. W. Cunningham has been appointed manager. Herber & Co., leasing on the Independence through the Wilcox adit, are shipping on an average of three carloads of smelting ore each week. The product is consigned to the Salida smelter and returns averaging \$38 per ton are being received. Carload shipments are going out from the Virginia City on Lincoln mountain. The ore shows a fair quantity of 'wire' silver and brings a net settlement of \$45 per ton. A. Robert is operating under lease. Work was resumed this week on the Central Capital mine, situated on Griffith mountain. Shipments of lead-zinc ore are to be started. The Argentine Central railroad is now delivering ore from the mines of East Argentine. Shipments are going out from the Kittle Ousley, Tobin, Santiago, and Waldorf mines. B. J. O'Connell, operating the Gambetta mine on Republican mountain, has secured a right-of-way and lease upon the Magenta-Turner vein, cut 850 ft. from the portal of the adit. The west drift will be extended for 1300 ft. to undercut the Gambetta workings by 400 ft. Heavy shipments are being made from the Ohio property on Lincoln mountain, operated by the Bard Creek M. Co. The product is worth \$55 per ton in gold, silver, and lead. F. Nelson is manager.

Georgetown, August 8.

LAS ANIMAS COUNTY

Labor is unsettled in the southern Colorado coalfields, and the United Mine Workers of America are discussing the situation at Trinidad. If a strike is declared, it will involve several thousand men in district 15, comprising Utah, Colorado, and New Mexico.

TELLER COUNTY (CRIPPLE CREEK)

The new ore-shoot in the El Paso company's property was opened on the 900-ft. level of the new Nichols shaft, this level corresponding and connected with No. 6, or 800-ft., level of No. 1 El Paso shaft on the south end of the estate. These blocks are situated south of the Nichols shaft, and the discovery is on the Beacon hill Ajax vein. The orebody, which is 5 to 8 ft. wide, has already been proved horizontally north and south for a distance of 175 ft., with rich ore in both headings and back of the drift. The vein contains streaks of sylvanite, some being 1½ to 2 in. wide.

The active mines on Beacon hill include the Commonwealth, Requa Savage, Gold Dollar, Black Belles, and Prince Albert on the eastern side, the Prince Albert and Hiawatha on the south, with the properties of the Henry

Adney Gold Mining Co., the Henry Adney & Maid of Orleans, and the El Paso Consolidated estate with two shafts and an adit.

THE SAN JUAN

On No. 6 level from No. 3 shaft the Camp Bird company has cut the vein again, which is similar to the level above. During July 265 ft. of work was done in the Mountain Top mine, of which 168 ft. was on the vein. In the north drift the vein was from 2½ to 6 ft. wide, with a streak 8 in. averaging \$8.14 gold and 64.84 oz. silver per ton. The last 20 ft. averaged 18 in. wide.

Crude ore and concentrate shipments from Silverton during July were as follows: concentrate, Gold King, 725 tons, Sunnyside, 660; Iowa Tiger, 468; Barstow, 460; Frisco Tunnel, 60; and Intersection, 19 tons; and ore, So. Expl. & Mining Co., 347 tons; Silver Lake lessees, 282; Dives, 132; Gold Tunnel, 130; Allerton, 108; Aspen, 62; Sultana, 40; Celtic Leasing Co., 24; Contention, 23; Perlino, 21; Dr. Fox, 20; Frank Hough, 15; and Bonner, 15 tons.

The Tomboy mill worked 29 days in July and treated 11,500 tons of ore, yielding \$23,000 in bullion and \$60,500 from 1400 tons of concentrate shipped. Working expenses were \$48,000, and the estimated profit \$35,500.

IDAHO

SHOSHONE COUNTY

It is stated that the Federal company is planning to enlarge its concentrating plant at Mullan, and that the slime will be properly treated. Net earnings of the Stewart Mining Co. in July were \$70,000, and it is expected that regular quarterly dividends will result from the profits now being earned.

MICHIGAN

HOUGHTON COUNTY

The strike is being continued in a half-hearted manner, and about 75% of the Calumet & Hecla employees have asked for work. Western Federation members are deserting the cause and tear up union cards, while business men and men returning to work will stand by one another. The miners' union at Butte, Montana, has sent a second installment of \$7000 to Houghton to help support the strikers. 'Mother Jones,' said to be the greatest labor agitator in the United States, has suddenly left and gone to Washington, D. C., to enlist the support of certain senators.

The Calumet & Hecla Mining Co. reported its condition at April 30, 1913, as follows: Real estate, \$48,146,329; merchandise, \$5,190,789; cash and debts receivable, \$3,788,526; and holdings in other companies, \$15,025,438; a total of \$72,151,082. Liabilities include capital stock, \$12,000,000; accounts payable, \$396,758; profit and loss, \$66,420,324; and indebtedness, \$4,134,000. Officials of the Company announced on August 9 that enough of the men who have been on a strike had agreed to return to work to enable the Company to resume its operations. The Company claims to have 3000 men ready to work. The Western Federation of Miners officials, who have been in charge of the strike, asserted that not enough men would return to bring about anything like normal conditions.

MISSOURI

ST. FRANCOIS COUNTY

All the mines in the lead belt of this county were closed on August 15 on account of the strike of 5000 members of the Western Federation of Miners. The closing resulted from the failure of a conference between representatives of the companies and the union. The miners ask 30 cents per day increase and recognition of the union.

MONTANA

FERGUS COUNTY

(Special Correspondence.)—The Barnes-King Development Co.'s earnings for July did not come up to expectations, and it now seems as if it will be November 1 before the earnings will be sufficient to pay off the indebtedness and receive a clear title to the North Moccasin property. A considerable amount of low-grade ore was treated, bringing the net bullion returns down to \$7.33 per ton as

against \$9.60 per ton in June. The gross earnings for July were \$32,113, as against \$35,387 in June—a decrease of \$3276. The balance still due on the North Moccasin property is \$41,844. Development work is making fine progress, and the improvements at the Barnes-King mill are so far advanced that there is no doubt they will be finished by the end of the present month.

Kendall, August 15.

LINCOLN COUNTY

(Special Correspondence.)—J. B. Arons, of Duluth, Minnesota, who is interested in the Montana group of silver-lead mining claims on Cherry creek, has been in town during the past week. A number of men have started work on development. S. F. Ralston, manager of the Kalspell-Lincoln Gold Mining Co., came in from the property recently with about 60 oz. of gold taken from the last clean-up. The Company's 5-stamp mill is being operated steadily at the property on West Fisher creek.

Libby, August 10.

SILVERBOW COUNTY

To enforce demands made for higher wages and Saturday half holidays, 200 electrical linemen of Butte and its vicinity declared a strike on August 12. Local telephone and power distributing companies say that on the strikers must rest all responsibility, since they gave the companies no chance to arbitrate or otherwise adjust the issue at stake. It is said that this strike will not affect the mines and plants working, unless a transmission line breaks down. A recent dispatch states that the men are returning to work.

The East Butte Copper Mining Co. makes the following statement for the quarter ended with June:

First-class ore mined, tons.....	22,664
Average copper content, per cent.....	6.4
Second-class ore mined, tons.....	6,485
Average copper content, per cent.....	2.96
Copper shipped, pounds	3,724,241
Silver shipped, ounces	140,980
Gold shipped, ounces	3,484

NEVADA

CLARK COUNTY

Fire destroyed the 40-stamp mill, engine-room, and the power-plant at the Quartette mine, near Searchlight, on August 20. The loss was \$115,000, only a small part of which was covered by insurance. The assay offices, stables, and other buildings at the mine were saved by hard work on the part of the miners.

LYON COUNTY

At the Casting Copper division of the Nevada-Douglas property, the development on the 100 and 200-ft. levels is opening a large quantity of low-grade ore which will figure in the present plans for leaching. This ore, which is proving to be of large width, will average between 2 and 3% copper. Neither cross-cut as yet has reached the lime foot-wall. Work along the contact to the east on the 40-ft. level shows low-grade ore in the face. The back of the No. 1 stope is about 40 ft. above the level, with the ore remaining about 6 ft. wide. The June quarterly report of the Mason Valley Mines Co. states that the property produced 31,336 tons of ore, and smelted 59,494 tons yielding 3,587,693 lb. of copper. The net profit was \$44,551. During the week ended August 13, the smelter treated 4020 tons of ore and shipped five cars of matte.

Foundations for the new converters at the Mason Valley smelter are almost completed, while iron flues to carry the converter fume to the main flue are being made at the smelter shops. A large motor-driven air-compressor is also being installed to provide air for the converters.

MINERAL COUNTY

The foundations for the 100-stamp mill at Aurora are nearly complete, while material is being shipped to the site as fast as the bad roads will allow teams to work. It is said that 20 stamps will be retained for customs ores.

NYE COUNTY

Eleven mines at Tonopah produced 12,310 tons of ore worth \$283,790 during the past week. In July, the Bel-

mont treated 13,558 tons yielding 339,903 oz. bullion, at a profit of \$175,603. The Tonopah company treated 14,250 tons yielding 222,625 oz. and 106 tons of concentrate valued at \$226,575, at a profit of \$123,550. The West End treated 4045 tons at a profit of \$8.54 per ton. At the Halifax, the ore has been proved to be 36 ft. wide between walls of trachyte, but in the centre of the vein is an intrusion of trachyte 9 ft. wide. Apart from this, the average value of the ore is of good grade. On the 1050-ft. level of the North Star, the east drift is in lower-grade ore than usual. The winze below the Midway 600-ft. level is opening 4 ft. of \$50 to \$80 ore. The west drift on the 1170-ft. level of the Merger has cut rich black sulphide ore. At Manhattan, the War Eagle mill is treating 115 tons of ore per day from the Riley Fraction lease, and has treated 7500 tons of low-grade ore so far.

OREGON

JOSEPHINE COUNTY

Numbers of mining men are arriving at Grants Pass in connection with mine examinations. Arthur H. Gruber and associates of Milwaukee will provide capital to equip the Old Glory mine, on Silver creek, with modern plant. James W. Neill, of Pasadena, California, has secured an option on dredging ground on Grove creek, near the Columbia mine, and prospecting is under way. About 1500 acres of dredging ground, situated on Pleasanton creek, 17 miles from Grants Pass, is being tested by J. K. Kendrick of California. The Bill Nye mine is being developed by French people.

UTAH

JUAB COUNTY

The Victoria mine is being sampled by the Eagle & Blue Bell officials. Surveyors are examining the Centennial Eureka in connection with the suit for alleged wrongful extraction of ore from the Emerald company's property. Promising development is under way on the 1100-ft. level of the Emerald mine. The Colorado is shipping 100 tons of 15 to 20% and 40 to 45 oz. silver ore per week.

SALT LAKE COUNTY

The Utah Copper Co. produced 9,849,043 lb. of copper in July.

SUMMIT COUNTY

Ore shipments from Park City during the past week were as follows: Silver King, 794 tons; Daly-Judge, 393; Daly West, 261; American Flag, 60; and King Consolidated, 27 tons. A large orebody is said to have been opened in the Silver King Coalition in a drift off the main Alliance adit.

WASHINGTON

FERRY COUNTY

Another chapter was added last week to the series of changes in the past few months involving the Republic Mines Corporation, owning and operating mines at Republic, when the properties passed into the control of J. L. Harper, former general manager for the Company, and his associates, under a two-year bond, for \$600,000. The first payment of \$100,000 is to be made January 1, 1914, the second, of \$200,000, on August 15, 1914, and the remaining \$300,000 is to be paid on or before August 15, 1915. The purchase contract stipulates, however, that payments may be made on a royalty basis, of from 10 to 40% of the net smelting returns from shipments from the mines, depending upon the grade of the ore, but that the installments must be made as agreed, regardless of whether a sufficient amount is produced by the properties.

KITTITAS COUNTY

(Special Correspondence.)—The 10-stamp mill on the Cougar mine, at Liberty, is running steadily on a good grade of ore. H. D. Harkness is doing well with his placer claim, and last week one nugget netted him \$257. J. Powles has bonded his placer claim in Louis gulch to Seattle people. The old placer dumps on Williams creek were leased to J. F. Powers and J. T. Sugars. These dumps consist of thousands of tons of unwashed gravel and contain about 20c. gold per yard. A 1000-ft. flume

is under construction, and the ground-sluicing method will be employed.

Jack Stuart has a crew of men working on his placer at the junction of Lions and Williams creeks. The 'pay' channel in Lions gulch has been reached within the past few days. Jake Livingston has been working profitably at his placer on Swank creek for several months. There is plenty of water for hydraulic purposes. Ben. Killson, owner of the Hope quartz mine, near Liberty, is now mining high-grade ore.

Liberty, August 15.

MASON COUNTY

(Special Correspondence.)—A manganese-copper property is being opened by a company on the Olympic peninsula. About 20 tons of 4% copper ore is mined daily and put on the stock pile.

Seattle, August 15.

CANADA

BRITISH COLUMBIA

The Rossland payroll is now the largest in history, for in addition to the miners in the Consolidated company's employ there are 200 to 300 working in the many smaller mines under development in the vicinity. New mining machinery has been installed recently at the Center Star, Le Roi No. 2, War Eagle, and Josie, and the result is a heavily increased output and a material reduction in operating expenses. The four properties are shipping 25 cars of ore per day to the Trail smelter. There are now seven furnaces in blast and 600 men are employed.

Ladysmith, one of the coal towns on Vancouver island, where the miners have been on strike for several months, was in a riotous state on August 14, and the militia was called out to maintain order. Shipments of rich gold and silver ore from the Union group, at Gloster camp, 45 miles from Grand Forks, are now being sent out. During July, the Granby smelter treated 100,748 tons of ore, yielding 1,654,000 lb. of copper, and in the first seven months of the year a total of 727,348 tons, producing 12,665,697 lb. of blister copper. Steelite, the new explosive, is being used at the Argo mine. The British Columbia Copper Co. will shortly begin the erection of a concentrator at Boundary Falls to treat ore from the Lone Star mine. It is reported that the Granby company has bought the Big Copper mine, about five miles from Greenwood.

ONTARIO

Members of the International Geological Congress visited the old Wright mine near Lake Timiskaming. It is said to be the oldest silver property in North America, there being a stake near the mine bearing the date 1744.

The new cyanide plant at the Porcupine Crown mine

PORCUPINE AND DISTRICT.

is making good progress and should be complete in about forty-five days. The 10-stamp mill is extracting from 82 to 87% by amalgamation, treating 65 tons of \$22 ore per day. At the mine the main vein has been found beyond the fault on the 200-ft. level by the diamond-drill.

The Hollinger company reports for the term ended July 15: The mill treated 10,056 tons of ore averaging \$19.70 per ton, with an extraction of 96.5%. The month's profit was \$129,147. Mining costs were \$3.04 and treatment \$1.65 per ton. Profits for the current year are \$851,668, and the surplus after dividends, \$573,469. Work upon the winze below the 300-ft. level of the Hollinger has been continued,

and the winze has now reached a depth of 113 ft. The vein dipped out of the winze at 94 ft. The winze will be carried to a depth of 125 ft. before cutting the station, thus making the next level 425 ft. depth. The vein should be cut within 20 ft. of the winze on the 425-ft. level.

Shipments of silver from Cobalt totaled 139,117 oz., of which 129,164 was from the Nipissing and 4052 oz. from the Kerr Lake. The latter was sent out in one mass, owing to trouble in the melting-room. The bullion was cooled down in the crucible and shipped in that form.

In July the Alexo mine at Iroquois falls, shipped 794 tons of nickel ore to the Mond Nickel Co.'s works.

YUKON

Jacob Nielson, who was charged with dynamiting the Yukon Gold Co.'s No. 1 dredge on February 24, was found guilty at Dawson on July 31, after a ten days' trial, and sentenced to twenty years' imprisonment. Forty witnesses were called for the prosecution and sixteen for the defense, and there were 74 exhibits produced.

KOREA

A cable received in New York by the Oriental Consolidated Mining Co. advises that the clean-up for July was valued at \$140,000. The following details supplementing the cable information already published regarding the June clean-up has been received by mail from Korea:

Tabowie mill	\$ 28,026
Taracol mill	21,860
Kuk San Dong mill	3,113
Malbong mill	21,709
Candlestick mill	11,143
Taracol tube-mill	43,651
Kuk San Dong cyanide plant	3,896
Kuk San Dong dump plant.....	7,799
Candlestick cyanide plant	2,285
Total	\$143,482

The total tonnage milled during June was 25,919 tons. The Candlestick mill ran during June on ore broken during that month and during May. This plant is shut down again, owing to the scarcity of labor in the mine. So far, it has been difficult to obtain sufficient miners to keep the mill running. All of the mills are being operated by steam power, owing to the lack of water for the hydro-electric power-plant.

MEXICO

AGUASCALIENTES

It is stated that ore valued at \$3,000,000 is at present awaiting treatment at the American Smelting & Refining Co.'s plant at Aguascalientes. The smelter has been operating at reduced capacity for some time, owing to the difficulty in getting supplies for the furnaces.

WESTERN AUSTRALIA

(Special Correspondence.)—Developments in the Horse-Shoe mine continue to be satisfactory, and the winze on No. 4 lode to the 2780-ft. level has opened 16 ft. of \$15.12 ore, while another winze has opened rich ore on the west branch lode. Owing to the departure of many Australian miners from Kalgoorlie and other districts, there is a shortage, and Italians have been employed at several mines. At the Golden Ridge mine, because the Australians refused to work underground with some Italians, the management has closed the property, and 150 men are out of work. At the Sons of Gwalia, the stamp-mill is being overhauled, amalgamating and Wilfley tables dispensed with, the pulp flowing to pans for reduction and amalgamating, and sand to tube-mills. A new vacuum-filter plant is to be erected to treat all of the current slime. There are also certain changes being made in handling miners, which will save 100 working hours per day, and horses will haul cars underground instead of men. The Westralia Mt. Morgans is being reopened, and suction-gas engines will replace the old steam plant. Sulphide ore having been opened in the Victorious mine, Ora Banda, experiments are being made for its proper treatment.

Kalgoorlie, June 16.

Schools and Societies

THE University of California has registered 4646 students for the fall term which commenced on August 18.

THE Michigan College of Mines at Houghton fall term opens on September 26. There are 35 on the staff of instruction. The courses given and descriptions of the various buildings of this excellent College have been given previously, so there is no need to cover the matter again. The Year Book of the institution is full of interesting matter.

OLD FREIBERGERS in America are to give a complimentary dinner on September 9, at Scranton, Pennsylvania, in honor of Dr. Richard Beck, president of the Freiberg Bergakademie, Freiberg, Saxony, Germany, who is now in Canada attending the International Geological Congress. After the meetings of the Congress, Dr. Beck expects to visit several places in the United States before his return to Germany.

THE monthly meeting of members of the Geological Society of South Africa was held at Johannesburg on June 30. The following papers were open for discussion: 'Note on the Origin of the Iridosmine in the Banket,' by R. B. Young; 'Structural Features of the Western Witwatersrand,' by E. T. Mellor; 'Notes on the Sea-Point Granite-Slate Contact,' by E. H. L. Schwarz; 'Note on Diamonds in the Banket,' by R. B. Young; and 'Notes on a Section from Barberton to the Komati River,' by David Draper (honorary member). The following papers were read: 'The Bushman's River Cretaceous Rocks,' by E. H. L. Schwarz, and 'The Geology of Katanga and Northern Rhodesia—an Outline of the Geology of South Central Africa,' by F. E. Studt.

THE Wallace, Idaho, chapter of the State Mining Association was organized on August 15 by Ravenal Macbeth, the secretary. He opened the meeting with an address in which was outlined the objects and purposes and benefits of the state organization. Herman J. Rossl, chairman of the grievance committee, and Harry L. Day, president of the State Mining Association, pointed out the instances in which the Association had already benefited the mining industry of the state. Earl Greenough, a member of the executive committee, acted as chairman and Rush J. White as secretary. The permanent officers elected were E. H. Moffitt, president; Joseph F. Whalen, secretary; and Jerome J. Day, treasurer. The Burke chapter of the Association was organized on August 16.

THE University of Washington, College of Mines, at Seattle, summer session closed on August 1, and the first semester of the 1913-14 year starts on September 12. There are 37 members on the teaching staff. Excellent opportunities for becoming familiar with mining and metallurgical operations are open to students in the College of Mines. The amount of time available during the college year for this purpose is not great, and even by using the summer vacations it is impossible for a student to cover the whole field of local industries included in his chosen profession. Mining machinery of the best type is in operation within easy reach of the University. Much of the heavy mining machinery used in the neighboring states and Alaska is built in the city of Seattle.

THE COLORADO SCHOOL OF MINES regular session opens on September 2, while in the meantime the Summer School is in session. The object of this school, which is open during July and August, is to enable conditioned students to regain full standing. It is also available for applicants for admission to advanced standing, who may complete their requirements in the Summer School in advance of the regular session. The working schedules of the School of Mines proper have been revised and simplified, although without any omissions of importance as to subjects. There are few faculty changes. Harry J. Wolf, who acted as professor of mining during much of last year, is appointed to that chair. No other department has any change to announce in its leading men. The applications for admission indicate an increase over last fall. The graduation in May of 70 students illustrates the extent to which in recent years admission to advanced standing serves to augment the numbers in the upper classes.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

W. M. DAVIS is visiting Spokane.

R. CLYDE CAMERON is at Tonopah.

E. H. NUTTER has returned from New York.

THOMAS T. READ is visiting Toronto and Sudbury.

W. J. LORING left Australia for England early in July.

C. W. WRIGHT is visiting the United States and Canada.

W. F. LAMOREAUX has returned to Ducktown, Tennessee.

J. C. BRANNER arrived at Stanford University on August 13.

T. ANNEAR has been appointed superintendent of the mint at Denver.

JOHN T. ROBERTS, JR., of Buffalo, New York, is at Ouray, Colorado.

ROWLAND KING has left Greenwood, British Columbia, and is now at Spokane.

FRED V. BURNS has moved from Montezuma, Costa Rica, to Guanajuato, Mexico.

VERNE A. STOUT has returned to San Francisco from Pichucalco, Chiapas, Mexico.

W. W. MEIN and RALPH STOKES were at Hedley, British Columbia, during the past week.

JOHN DERN has returned to Salt Lake City after spending five months in Germany and Austria.

A. H. HEUSER, formerly of Charcas, San Luis Potosi, Mexico, has gone to Dona Ana, New Mexico.

WALDEMAR LINDGREN returned from Mexico in time to attend the International Geological Congress at Toronto.

C. K. LEITH and J. F. KEMP are in eastern Canada and northern New York examining the Grenville series of rocks.

GEORGE OTIS SMITH presided at the session of the International Geological Congress that was devoted to ore deposits.

BAILEY WILLIS, CHESTER WASHBOURNE, and J. R. PEMBERTON have returned from the Argentine and are busy preparing their reports at North Haven, Maine.

MORTON WEBBER has returned to New York after conducting examination work in New Mexico, and has left again for Canada, where he will be until about September 1.

W. R. CRANE, professor of mining in the Pennsylvania State College, has just returned from Alaska, where he spent the past year investigating the coal resources of that territory.

J. H. HOLMAN, a well known mining and machinery man of Cornwall, England, is reported to have been drowned in the wreck of the *State of California*, off the coast of Alaska, on August 18.

H. FOSTER BAIN will return tomorrow from Toronto and Butte, where he has been attending the meetings of the International Geological Congress and the American Institute of Mining Engineers.

F. DANVERS POWER, of Sydney, who was in charge of the Great Cobar during the absence of H. C. BELLINGER, is to take an extended tour, embracing Java, the Malay Peninsula, Japan, the United States, and London.

FRANCIS P. BRAY has just completed a visit of inspection to Mount Lyell, Broken Hill, and other mining centres in Australia, and is leaving for London by way of Manila, China, Japan, and across the Trans-Siberian railway.

CHARLES F. RAND and BRADLEY STOUTON will be in San Francisco on or about September 1, to confer with the San Francisco Chapter of the American Institute of Mining Engineers regarding the work to be undertaken by the local organization.

D. C. LIVINGSTON and C. A. STEWART have returned to Moscow from Dixie, Idaho, where they have been engaged in a geological survey of the district, the results of which will be published in bulletin form by the Mining Department of the University of Idaho.

The Metal Markets

LOCAL METAL PRICES

San Francisco, August 21.

Antimony.....	12-12½c	Quicksilver (flask).....	\$40
Electrolytic Copper.....	16-16½c	Tin.....	46-47½c
Pig Lead.....	5.00-5.95c	Spelter.....	7-7½c
Zinc dust, 1400 lb. casks, per 100 lb., small lots \$9.50-9.75; large \$7.50-8.50			

EASTERN METAL MARKETS.

(By wire from New York.)

NEW YORK, August 21.—The copper market remained strong, but with little buying reported. Reports from the large porphyry properties show heavy stocks on hand and in transit. The continuance of the strike in the Lake Superior district has had no appreciable effect on the general market. The lead and spelter markets are strong and active. St. Francois county strike has had no effect on lead. Cable from London quotes spot copper at £69 2s. 6d. and futures £69 3s. 6d. Lead is steady at £20 7s. 6d. Spelter £20 12s. 6d.

Little improvement has been shown in the London mining market, and public interest is at an exceedingly low ebb. While the feeling is general, it is particularly true of Mexican stocks and investments. It is hardly to be expected that mining affairs will take a turn for the better until some order is brought out of the present chaos in that country.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

Date.	Average week ending

Apr.	59.20	59.26
May	60.88	60.21
June	61.29	59.03

Business has been very limited this week, and, as only small orders have been received from China and India, most of the support has come from some special buying, but the daily offerings have again been small. It would appear, however, that the Mexican Government has discontinued the coinage of dollars, shipments of silver from that quarter to London having recommenced. Only a small amount goes to India this week, and London stocks are not far short of £4,000,000, according to Pixley and Abell's (London) circular of August 7.

ZINC

Zinc is quoted as spelter, standard Western brands, St. Louis delivery, in cents per pound.

June	6.88	5.00

Figures compiled by C. E. Siebenthal, of the U. S. Geological Survey, from reports by all zinc smelters operating during the first six months of 1913, and from the records of the Bureau of Foreign and Domestic Commerce, show that the production of spelter from domestic ore in that period was 171,135 short tons, and from foreign ore 9078 short tons, a total production of 180,213 tons of primary spelter, compared with 166,496 tons for the first half of 1912 and with 172,310 tons for the last half of 1912. This production for the first half of 1913 is at the rate of over 360,000 tons per year and approximately 20,000 tons greater than the production in 1912. The spelter made in Illinois increased over 9000 tons and that made in Kansas declined 6000 tons, compared with the quantities of spelter made in those states during the last six months of 1912. The apparent consumption for the period was 153,073 tons, as compared with 181,326 tons for the last half of 1912, and 159,046 tons for the first half of 1912. The stock of spelter held at smelters

on June 30, 1913, was 21,856 tons, as against 4522 tons at the beginning of the year, an increase of 17,334 tons.

The imports of zinc ore were 19,994 short tons, containing 9204 tons of zinc, as compared with 16,891 tons of ore containing 5339 tons of zinc in the last half of 1912, and 27,049 tons of ore containing 12,228 tons of zinc in the first half of 1912. The exports of domestic zinc ore were 9745 tons, as compared with 9640 tons in the last half of 1912 and 13,709 tons the first half of 1912.

At St. Louis spelter started the year at 7.25c., the maximum price for the first half of the year. For the greater part of January the price held this level, but there followed a long steady decline, broken by a slight recovery during the first half of March, which decline left spelter bringing a shade under 5c. per pound at the middle of June. A slight recovery through the latter half of June brought the price up to 5.15c. at the close of the period. The London price of spelter, on the contrary, was fairly steady through the first four months of the year.

COPPER

Quotations on copper as published in this column represent average wholesale transactions on the New York market and refer to electrolytic copper. Lake copper commands normally from 1-5 to 1-4c. per lb. more. Prices are in cents per pound.

QUICKSILVER

The primary market for quicksilver is San Francisco, California, being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 7½ lb., are given below:

BORAX PRODUCTION IN 1912

There was a decrease in the production of borate ores in the United States last year, according to Charles G. Yale and Hoyt S. Gale, of the United States Geological Survey. The output of borate ores in 1912 was 42,315 short tons, valued at \$1,127,813, as compared with 53,330 tons in 1911, valued at \$1,569,151. The quantity stated is that of the crude ore as mined for delivery at the mill or for shipment.

All the borax now produced in this country is derived from ores mined in California; in fact, virtually the entire product is derived from four mines, one in Inyo county, one in Los Angeles county, and two in Ventura county. Formerly borax was obtained from the so-called marsh or dry-lake deposits, which were worked in Nevada, California, and Oregon. The borax and horic acid now produced is derived wholly from deposits of borate of lime, in which colemanite is the entire source of supply.

There is a general impression that colemanite has been found in so many places and in quantities so large in relation to the small demand for borax and horic acid in the present market that there need be no fear of the exhaustion of the deposits. In fact, in nearly all deposits mining has proceeded with great rapidity and possibly in a more or less wasteful way. Mining entries are generally driven ahead somewhat at random, the pockets of ore being 'guttled' and shipped before attention is directed to the blocking out of ore in reserve. If this practice is continued, even the large deposits of colemanite now known will not last indefinitely, and the exhaustion of one after another of the workable deposits is expected. Since the discovery of colemanite in 1882, at least one large district has been worked out and abandoned.

Even should the richer deposits ultimately become exhausted, there are a great many other possible sources of supply, including the marsh deposits formerly worked, to which recourse could again be had. More important than this, a new factor is entering the field of the borax industry with very recent developments. The natural saline deposits of the western desert region have come into prominence as a possible source of potash, carbonate of soda, common salt, and other products, including borax.

SAN FRANCISCO MINT

The total receipts for July were 268,711 oz. of fine gold, valued at \$5,554,751.44. Including gold credited to domestic refineries, it is estimated that about \$1,500,000 of the total is new gold of California origin.

Company Reports

TALISMAN CONSOLIDATED, LTD.

This Company was formed in 1899 to acquire gold mining property at Karangahake, in the province of Auckland, New Zealand. Since then the adjoining properties of the Woodstock Gold Mining Co., the New Zealand Talisman Gold Mining Co., and the Imperial Gold Mining Co. have been purchased. The report covers the year ended February 28, 1913, and that of the superintendent, H. Stansfield, includes the following:

Development covered 2547 ft. On No. 13 level, which is about 1900-ft. below the top of the mountain, and 200 ft. below the Waitawheta river, at 1754 ft. in the main south drift a cross-cut was driven westward 15 ft., which intersected 3 ft. of ore that averaged \$35.16 per ton. In driving southward, ore was exposed averaging \$38.94 per ton for a width of 3 ft. 6 in. and for a length of 53 ft. At 1780 ft. south a raise, No. 17, was driven 15 ft. in ore that averaged \$46.62 for a width of 2 ft. 8 in. In a winze, No. 17, driven from the same point, the ore averaged for the first 58 ft. \$21.14 per ton for a width of 3 ft. 3 in., and

TALISMAN MILL AND VIEW OF KARANGAHAKE, NEW ZEALAND.

from 58 ft. to 84 ft. averaged \$1.44 per ton for a width of 2 ft. 6 in. Further work has been discontinued until the No. 14 level south drift reaches this point.

On No. 14 level the south drift has been extended 220 ft., making a total of 1086 ft., sampling as follows: from 866 to 914 ft. the vein averaged 2 ft. 6 in. wide with low metal content; from 914 to 931 ft. it was 4 ft. 6 in., worth \$19.64; from 931 to 1024 ft. it averaged 4 ft. wide of low grade; from 1024 to 1059 ft. the average was \$15.88 per ton over a width of 4 ft. 6 in.; and from 1059 to 1086 ft. it was 4 ft. wide and again in low-grade material.

The Talisman and Woodstock shafts were sunk a farther 54 and 186 ft. below the river level, respectively, to 562 and 454 ft. depth. The estimated ore reserves are 47,653 tons averaging \$29.48 per ton, exclusive of ore below No. 14 level.

The year's results were as follows:

Ore treated, tons	42,980
Bullion recovered, ounces	291,453
Value	\$1,162,000
Total revenue	1,200,000
Mining, treatment, construction, etc.....	460,000
Balance after all expenditure	690,000
Dividends	624,000
Total dividends	3,783,000
Balance brought forward from 1912.....	105,000
Depreciation and taxes	100,000
Investments at cost price	230,000

Water in the main shafts and labor troubles hampered operations. The report is accompanied by the examination of Bewick, Moreing & Co., and excellent plans. The accompanying half-tone will give an idea of the country where the property is situated.

CHIEF CONSOLIDATED MINING CO.

The half-yearly report of this Company, operating at Tintic, Utah, contains the following:

Development, feet	4,064
Ore shipments, tons	30,854
Metal content:	
Gold, ounces	2,489
Silver, ounces	632,897
Lead, pounds	245,171
Net return	\$206,569
Balance on hand	303,023
Other receipts	9,744
Total	\$519,336
Operating costs	122,776
Sundry expenses	27,452
Dividend No. 1	87,645
Balance on hand	281,462

The superintendent, Cecil Fitch, states that plans for the rapid opening of the mine were continued and all the work possible in this line and for mining the ore was done to the limit of the shaft capacity. It is hoped that an opportunity will be found to stop the work long enough, in the next six months, to permit of the completion of the widening of the upper part of the shaft. So far, it has been impossible to do this. When this work can be carried out it will permit of working a second cage and thus nearly doubling the shaft's capacity, and allow of a larger production of ore and also of increasing the amount of development, of which there is a large amount to do.

The cross-cut to the Gemini mine was completed and much benefit is being derived from the better air in the workings, besides furnishing a necessary second outlet through that mine, and also this drift supplies an opening for the carrying on of work in ground promising for ore heretofore not available. The length of the cross-cut is 2135 ft. There has been a large increase of the ore in sight, there will be no difficulty in maintaining the present product, and it is hoped that in the remaining six months of the year the metal content will improve.

SHANNON COPPER COMPANY

The report of this Company for the second quarter of the current year gives the following information:

Ore mined, Shannon group, tons	69,051
Ore mined, other properties, tons	13,367
Copper produced, pounds	3,243,181
Gold, ounces	423
Silver, ounces	21,925
Average price received for copper, cents per pound	15.107
Total cost, cents per pound.....	14.434
Net profits	\$28,720
Cash, copper, and accounts receivable.....	187,042
Accounts payable	100,256

This shows a decrease in copper production of 406,383 lb. and \$47,127 in profit as compared with the March quarter. This is due to lower-grade ore being mined, fluctuations in copper content being frequent at the Shannon. The Shannon-Arizona railway earnings continue to be satisfactory, the net profit, interest deducted, being \$6883, against \$5956 for the preceding quarter.

CHINO COPPER COMPANY

This Company has issued its quarterly report containing the following: There was removed by steam-shovels a total of 923,708 cu. yd. of material measured in place, an average of 307,903 cu. yd. per month. Of the total amount so removed, 701,865 cu. yd. was stripping, the remainder of the yardage being ore equivalent to 460,751 tons. During the period, additional steam-shovels and locomotives were received, bringing the total equipment at the mine up to 10 shovels and 19 locomotives, thus providing ample equipment to permit of an ordinary percentage of it being out of commission for repairs without interfering with regular and uniform operations. Some scarcity of water supply prevailed during the quarter, owing in part to an unusually dry season. These conditions did not result in any actual

decrease in production, as the mill was able to receive all the tonnage the mines could economically furnish. Steps are now being taken to improve the additional water supply purchased some months ago as a safeguard against excessively dry seasons and to provide for increased tonnages.

Somewhat less than 60% of the quarter's tonnage was produced from the Hearst area, and was of a fair concentrating quality, although containing a considerably higher percentage of iron sulphides than the average of this orebody, and therefore producing a correspondingly lower grade of concentrate. The remainder of the ore came from various portions of the property. A considerable portion of it was partly oxidized ores which had been deposited on stock piles in the earlier periods of the property's operation, and before the mill was completed. The admixture of so large a percentage of the character of ore just described resulted in lower average recoveries than for the previous quarter.

The average copper content was 1.88%, and extraction 64.48 per cent.

Ore treated, tons	492,852
Copper production, pounds	11,990,832
Net profits	\$716,757
Dividends paid	\$629,790
Copper on hand and in transit, pounds.....	14,519,877
Cost per pound of copper, cents.....	8.71

RAY CONSOLIDATED COPPER COMPANY

The following statement shows the results obtained by the Company's operations for the second quarter of the calendar and fiscal year 1913.

The gross production of the copper contained in concentrate was 13,402,394 lb. In addition to the copper contained in concentrate, there was produced 84,294 lb. of copper from ores shipped direct to the smelter without concentration. This added to concentrate contents brings the total production for the quarter to 13,486,688 lb. The total amount of ore milled was 587,877, as compared with 537,205 tons in the first quarter. The average mill recovery was 66.915%, as compared with 66.205% in the previous quarter. The total production of concentrate was 35,937,652 dry tons, containing an average of 18.647% copper. The ratio of concentration was 16.358 tons of ore into 1 ton of concentrate, as compared with 15.86 tons in the previous quarter. Milling cost 45.25c. per ton. Development covered 22,870 feet.

The orebody tributary to No. 1 shaft produced 62.4% of the tonnage; that at No. 2 shaft 35%; and that at No. 3 shaft 2.6%. The active stopes produced 39% of the tonnage; the reserve drawings 51%; and the development work 10%. This indicates a decrease of 4% in the development tonnage, and a corresponding increase in the stoping tonnage over results obtained in the previous quarter. The average grade of the ore was 1.7035% copper, as compared with 1.739% in the previous quarter. Development work from No. 2 shaft is continuing satisfactorily, and during the last half of the present year, stoping operations will have been carried along sufficiently to permit an increase of the percentage of ore obtained from the reserve drawing. This will result not only in an increase of tonnage, but a decrease in costs. The production of the relatively high-grade ore from No. 3 shaft averaged 165 tons per day of a grade containing 4½% copper. This tonnage will increase somewhat more rapidly in the immediate future, as workings have been extended from the shafts so as to permit of commencing stoping operations on two levels. Mining cost 73.92c. per ton.

The average cost per pound of net copper produced, after allowing for smelter deductions and after crediting income from the Ray & Gila Valley railroad against operating costs, but without so applying other miscellaneous income, was 9.558c., as compared with 9.5096c. in the previous quarter. The average cost per pound so derived during the two quarters is 9.5348c. This cost includes all operating and general charges, as well as a charge of 12½c. per ton of ore treated, or approximately 0.56c. per pound on the quarter's production for the extinguishment of the mine development expense. The profits were \$726,759.

The payment of dividends was commenced during the quarter at a rate of \$1.50 per share per annum, the first

quarterly dividend at that rate being distributed on June 30, and amounted to \$543,662.

Total amount of copper on hand and in transit (sold and unsold) was 16,833,979 lb., inventoried at an average value of 14.148c. per pound. The average inventory price of the unsold portion of this copper was 13.83c. per pound. At the end of the quarter, no copper due for delivery from the refineries remained unsold.

ISLE ROYALE COPPER COMPANY

This Company, operating in Michigan, reports the following for the first half of the current years:

'Rock' stamped, tons	250,123
Copper produced, pounds	3,326,655
Mining cost, cents per pound	13.46
Construction, etc	0.68
Smelting, etc.	1.47

Total, cents per pound	15.61
Dividend declared	\$150,000
Cash at Boston, copper and silver unsold.....	434,566
Cash, supplies at mine	110,055
Accounts payable	192,869

The showing in stopes and opening on the Isle Royale lode has not been up to the average of last year. The amount of openings has been at the rate of more than 25% greater than that of last year. The development work on the West or Grand Portage lode has given satisfactory results. About 66% of the drills now in use in the mine are of the Leyner-Ingersoll one-man type.

UTAH COPPER COMPANY

The following statement shows the results of operations of this Company for the second quarter of the calendar and fiscal year 1913.

The gross production of total copper contained in concentrate was 31,785,448 lb., against 23,884,467 lb. in the March quarter.

The financial results of the operations for the quarter, as compared with the first quarter of the year, are shown in the following table:

	Second quarter.	First quarter.
Net profits from milling operations....	\$1,832,071	\$1,110,346
Other income, rents, etc., in Utah.....	11,495	49,829
Nevada Con. Copper Co. dividend.....	375,187	375,187

Total net profit for the quarter.....	\$2,218,753	\$1,535,363
Dividends paid	1,186,627	1,186,627

Net surplus for the quarter.....	\$1,032,126	\$348,735
----------------------------------	-------------	-----------

The earnings for the quarter are computed on the basis of 15c. per pound for copper. The total amount of copper on hand and in transit (sold and unsold) at the end of the quarter was 33,620,594 lb., inventoried at an average value of 13.778c. per pound. At the close of the quarter no copper due for delivery from the refinery remained unsold.

During the quarter there was removed a total of 1,225,343 cu. yd. of capping, as compared with 822,246 cu. yd. removed during the first quarter of 1913, being an increase of 403,097 cu. yd. It is expected that the third quarter will show a further improvement.

The operations of the Bingham & Garfield railway were satisfactory. An average of 14,855 tons of ore per day was transported from the mines to the mills, as compared with 10,602 tons per day for the previous quarter. An average of 1928 tons per day of other freight was transported over the line, as compared with 623 tons per day, and passenger train receipts also showed a substantial increase.

There was treated at both plants a total of 1,910,214 tons of ore, as compared with 1,460,707 tons. Of this tonnage, the Magna plant handled about 55% and the Arthur plant about 45%. The average grade of ore was 1.2807% copper, as compared with 1.2495% copper.

Both plants were in continuous operation throughout the term, and treated a larger tonnage than during any previous quarter, averaging practically 21,000 tons per day.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

NITROGEN in the guano by the *Compania Administradora del Guano, Limitada*, on South Chincha island, South America, averaged 9.18% during the fiscal year 1912-13. The production was 24,350 tons.

CONVEYOR BELTS are being installed in the open-cut of the Mt. Morgan mine, Queensland, to carry waste to the passes leading into the mine; also underground to convey waste where at present hand tramming is employed.

A THICK PASTE of flake graphite and oil will prevent spark-plugs from sticking. The graphite will prevent adhesion of the metals and stop leakage as well. This mixture is also useful on bolts which are subjected to considerable heat.

ORE BROKEN per mlnr and shoveler per shift in the Mt. Morgan mine, in 1912, was 2.72 tons, and ore broken delivered per underground employee per shift was 1.32 tons. The contract miners earned \$4.16, and contract shovelers \$3.10 per shift, and the cost of breaking ore from face to chutes, including explosives, was \$1.22 per ton.

EXPLOSIVES in the flues of the Tooele and Midvale smelters, in Utah, caused quite a lot of damage and are extraordinary. At these plants the Dwight-Lloyd slintering process is used for agglomerating ores. The trouble is caused by the presence of finely divided sulphur in the gases from these roasting machines, and at a favorable moment an explosion occurs.

SANITATION is the practical application of knowledge and science to the preservation of health, and health is man's credit at the Bank of Life. The successful operation of mines largely depends on the health of employees, which is only maintained by adequate ventilation, lessened risk from various accidents, and comfortable change houses. A contented man will show high efficiency in mines and mills if his surroundings are decent.

UNDER an act passed by the state legislature in 1895, citizens of Nevada may send ores and minerals to the State University, at Reno, and have them analyzed and assayed without cost. These samples must be taken from within the boundaries of the state of Nevada. While results are given to those interested, a record, open for inspection, is kept of such results, together with the history and district from where the samples came.

COSTS at the Associated mine, Kalgoolle, during its past fiscal year were as follows: development, 75c., equal to \$14.96 per ft.; mining, \$1.78; treatment, \$2.56; bullion account, 3c.; general, 18c.; and insurance, 5c. per ton. The power cost was \$1.06 per ton. Mill extraction averaged 93%. The mine is opened to 2200 ft., and the mill consists of a Gates crusher, 4 Krupp ball-mills, 4 Edwards roasting furnaces, 20 grinding pans, 6 A. Z. agitators, 8 Dehne filter-presses and pumps.

IT HAS BEEN ANNOUNCED by the Decimal Association that the Standards Department of the Board of Trade has decided to adopt 200 mg. as the standard of the British carat, for weighing jewelry, precious stones, pearls, etc., and it is believed that an order to that effect will be issued probably before the end of the year. The metric carat of 200 mg. is 0.00643 and the present British carat in use 0.00660 ounce troy. Though the British carat hitherto in force, of which 151½ equal a troy ounce, is at present, so far as the precious metals are concerned, only applicable to retail business such as that of jewelers, this step toward unification with the almost universal metric system is interesting. Last year a committee was formed to promulgate the passage of a law making the metric carat effective throughout the United States of America.

THE greatest long-distance power transmission in southern Asia is in the native state of Mysore, power being transmitted from the Cauvery falls to the Kolar goldfields, 92 miles away, and to the cities of Mysore and Bangalore, about 40 and 86 miles away, respectively, for electric lighting and power purposes. Nearly all of the hydro-electric installation for this great enterprise was made in Schenectady, New York, and the only imports connected with this work not from the United States were water-wheels imported from Switzerland. An important extension for this great enterprise has recently been started, and the contract for all machinery except water-wheels has gone to the United States. Power is sold to the mining companies at \$48 per horse-power year.

CONTRARY to the usual practice, no regularity in depth of holes was possible at the Mt. Royal tunnel, Canada, due to the character of the rock. A long round of six or seven feet, at times alternated with a short round of four or five feet, and great credit is due to the men for the judgment used in the number and depth of holes required for each round. Usually six rounds were drilled and shot each 24 hours. Forcible dynamite of 60% strength was used and exploded by No. 8 electric exploders, comparing in strength to Canal Specials, and the round was fired from the wires used for lighting the heading, at a switch generally kept at about 700 ft. from the face, and on the opposite side of the heading from the lighting system. The amount of dynamite used in each round varied, and it was found necessary to blast the cut twice before it broke to the bottom. Occasionally the relief holes were shot with the second shot in the cut, but quite often the old holes left in the cut were loaded the third time and shot with the relief holes.

FIRST-AID work is studied by many miners and millmen at Kalgoolle, there being regular lectures given by local doctors, and examinations are held for proficiency. The mines are all equipped with up-to-date ambulances and hospitals, and victims of accidents receive prompt attention. On Labor Day, June 18, competitions in first-aid were held, the following giving an idea of the work done. The test given was a severe and comprehensive one, occupying 1¼ hours, and was divided into the following parts: (1) treatment of compound fracture of right leg and fractured lower jaw; (2) treatment of broken right fore-arm, arterial hemorrhage, dislocated left ankle; (3) treatment of severe burns on right leg and left foot and left side of face and head; (4) carry man forward by two-handed seat, then apply artificial respiration (Schaefer method), return by three-handed seat and treat for shock; (5) fireman's lift forward, place on stretcher, and carry over obstacle. A keen contest ended in favor of the Great Boulder mine No. 2 team, which won the Miners' Union's valuable trophy; with Penman's Boulder team a good second, and the Great Boulder mine No. 1 team only a point behind.

A DRILL CARRIAGE for mounting heavy drills was used in driving the Mt. Royal tunnel in Canada. The one designed by S. P. Brown had an arm carrying the cross-bar and drills, which may be advanced about 20 ft. ahead of the frame; also a belt-conveyor supported on a movable frame, which may be advanced eight or ten feet ahead of the frame proper, so that the end of the conveyor belt may be kept close to the rock pile. After each shot is fired the shovelers go ahead of the machine and throw the rock off the track, which is rlyeted to a steel plate until the machine gets close enough to the heading to place the bar carrying the drills, the heading being drilled from one position of the bar. From December 1, 1912, until May 1, 1913, a period of 5 months, the average monthly advance was 344.2 ft., the advance for the month of April being 351.4 ft. (without carriage). During May the 10 by 12½-ft. heading was advanced 510 ft. in 27 working days; in itself no mean record. This was done in extremely hard rock, and the waste was all removed as soon as, if not before, the drilling was finished. There has been no delay due to this machine since its installation, which is a remarkable performance for a new machine for tunnel work.

The Leadville Drill Column Hoist

The utility of such a hoist is now so generally recognized by mining operators that it is hardly necessary to describe the applications and advantages of this compact and ingenious piece of machinery. The manufacturer's aim has been to develop a simple and powerful compressed-air hoist to be mounted on a drill column for winze and stope work.

The absence of rods, levers, exposed gears, etc., as compared to other similar devices, is to be noted. The weight is easily balanced. There are no overhanging parts to be damaged in handling. The gears, where necessary, are provided with gear guards. The motor is entirely enclosed and reversible. The frame, for strength and lightness, is a rolled steel channel section. The hoist is mounted centrally on this to avoid any overhang or unbalanced condition in handling or operation. Securely riveted to the frame is a 4½-in. standard air drill clamp. When so desired this can be furnished with interchangeable bushings for 3½-in. columns.

The motor is a reversible, 2-hp., square-piston, air-engine, which has been in use for the past fifteen years, and has proved rugged and dependable. The enclosed construction, the absence of connecting rods, and exposed moving parts make this motor an ideal one for the purpose. The drum is mounted directly on the engine shaft. The hubs are bronze bushed. Convenient spring covered oil openings are provided. The drum can be instantly released for lowering by sliding the driving pinion out of mesh, although in many cases operators prefer to lower by reversing the motor. The main gear is cut phosphor bronze, bolted to the drum and shielded from the operator by the projecting brake rim. Both pinions are steel forgings, machine cut. The end of the drum shaft is carried in a phosphor bronze casting, forming at the same time a gear guard for the intermediate gear and pinion. The fly-wheel carries the sliding pinion for releasing the drum. A spring ball catch holds it in either position. The brake band is lined with genuine Gandy belt. A forged lever with quadrant teeth is conveniently placed for the operator. The brake band is provided with adjustment for wear. The hoist is manufactured by the Hendrie & Bolthoff Mfg. & Supply Co., of Denver, Colorado.

Portable Electric Lamp

The United States Bureau of Mines has recently issued Technical Paper 47, by H. H. Clark, entitled, 'Portable Electric Mine Lamps.' The paper states that the safety of mining operations will be largely increased by the abandonment of flame lamps, except for gas testing, and the substitution of portable electric lamps. The locked safety lamp is the only portable lamp now used underground that is comparable as regards safety with a well constructed portable electric lamp. Although an electric lamp cannot be regarded as a safety lamp, if the latter be defined as a lamp that detects the presence of gas without igniting it, still if the presence of gas is known, a well constructed portable electric lamp, even without special safety devices, would seem to be quite as safe as a safety lamp, because while either may possibly ignite gas as the result of an accident, an unbroken safety lamp may cause disaster if its parts are improperly arranged. In Europe the hand lamp is used almost exclusively, but the sentiment in the United States seems to favor the cap lamp, probably because there are so many open light mines in this country. The author summarizes as follows the more important considerations in the design of portable electric lamp equipment: After safety, the next consideration is the production of a proper amount of light for approximately ten hours on one charge. The next is reliability of service, which is followed by lightness and durability. Convenience in handling and charging is an important characteristic. The outfit should not leak or spill electrolyte, and it should not be necessary for the users to exercise care to prevent such leakage. The battery should hold its charge during long periods of idleness. The Bureau of Mines is at present engaged in an investigation of all the patterns of portable electric mine lamps that, as far as the Bureau is

aware, are manufactured in the United States. Any manufacturer of portable electric mine lamps may have his equipment included in this investigation by applying to the director of the Bureau for permission to submit equipment for test. Upon receipt of such a request the director will inform the applicants how many outfits and spare parts will be needed and where and to whom the equipment should be shipped.

Recent Publications

SECTIONS OF THE SYDNEY COALFIELDS, CAPE BRETON. By Joseph G. S. Hudson. Special edition for the International Geological Congress. P. 6. Tables, maps, and 15 colored plates. Department of Mines, Ottawa, 1913. These fields were first opened in a small way in 1672, and in 1912 the production was 5,197,601 tons.

MANUAL FOR ENGINEERS, published by the University of Tennessee. This manual is a small hand-book of interesting and valuable data compiled for the engineer's use by Charles E. Ferris, professor of mechanical engineering at the university. Copies will be delivered on receipt of 50c. by Charles E. Ferris, University of Tennessee, Knoxville.

United States Geological Survey publications, Washington, 1913:

SURFACE WATER-SUPPLY OF THE UNITED STATES, 1911. Part VIII. Western Gulf of Mexico. By W. W. Follett, W. B. Freeman, and G. K. Larrison. Water-Supply Paper 308. P. 117. Ill., map, index.

Advance chapters from 'Mineral Resources of the United States, 1912':

THE POTTERY INDUSTRY. By Jefferson Middleton. P. 16.
PRODUCTION OF MINERAL PAINTS. By James M. Hill. P. 26.
PRODUCTION OF BAUXITE AND ALUMINUM. By W. C. Phalen. P. 16.

PRODUCTION OF SAND AND GRAVEL. By Ralph W. Stone. P. 18.

PRODUCTION OF TALC AND SOAPSTONE. By J. S. Diller. P. 32. Maps.

Catalogues Received

NATIONAL TUBE Co., Pittsburgh, Pennsylvania. Booklet, 'The Whole Kewanee Family.' 48 pages. Illustrated. 5½ by 8 inches.

HENDRYX CYANIDE MACHINERY Co., 107 William street, New York. Catalogue No. 8. 24 pages. Illustrated. 6 by 9 inches.

ALBANY LUBRICATING Co., 708 Washington street, New York. 'The Bearing' for August. 12 pages. Illustrated. 4 by 6 inches.

SPRAGUE ELECTRIC WORKS, 527 West 34th street, New York. Bulletin No. 246, 'Motor-driven Exhaust Fan Outfits.' 12 pages. Illustrated. 8 by 10 inches.

INGERSOLL-RAND Co., 11 Broadway, New York. Catalog Form 9107. 140 pages. Illustrated. 6 by 9 inches. Covering entire line of this company, with dimension and capacity tables.

PITTSBURGH TESTING LABORATORY, Pittsburgh, Pennsylvania. Booklet C, 'Standard Specifications for Cement, Reinforcement Bars, and Concrete.' 40 pages. Illustrated. 4 by 7 inches.

CHICAGO PNEUMATIC TOOL Co., Fisher Bdg., Chicago. Bulletin No. 34-R, 'Class L-SS and L-SB Compressors.' Catalogue No. 43, 'Rockford Railway Motor Cars.' Both illustrated. 6 by 9 inches.

The GENERAL ENGINEERING Co., of Salt Lake City, Utah, having completed exhaustive tests on the ores of the National Copper Mining Co. of Wallace, Idaho, has been employed to design and erect a 500-ton plant. J. M. Callow is now on the ground with a corps of draughtsmen. Construction work under direction of Karl Bernson, of the General Engineering Co., will start immediately, and the mill is expected to be under cover before snow flies.

EDITORIAL

LAKE SUPERIOR engineers are holding one of their periodical field gatherings in connection with the meeting of the Lake Superior Mining Institute, August 26 to 30, inclusive, while in the first week in September Mr. C. K. Leith will guide a party of visiting geologists to the points of chief interest on the ranges.

REJECTION by the directors of the American Institute of Mining Engineers of the plan of affiliation with the Mining and Metallurgical Society of America, worked out by a joint committee of members of the two institutions, was announced at Butte. We believe that the directors of the Institute made a grave mistake in taking this action and we shall discuss the matter at length later.

IT seems to be a question in the minds of some farmers whether irrigation and alfalfa is as profitable as barren desert and smelter fume. With the experimental work which is now being conducted on smelter fume and with every prospect of success, it is gratifying to know that the day of the 'smoke-farmer,' as recorded in Mr. Herbert Lang's article in the current issue, is almost a matter of history.

THE strength of the present copper market is reflected in the advance of copper shares. In a period of less than three months there has been an appreciation of over \$100,000,000 in the value of thirty representative copper properties. The steady advance in copper since the middle of June, when it was selling at 14½ cents, to almost 16 cents at the present, has had a most beneficent effect upon the industry, and those who, two months ago, were fortunate enough to foresee the flood tide coming in the affairs of copper, are reaping the results of their investment. It is significant to note in this connection that the Lake Superior shares have kept pace with the general advance, regardless of the labor troubles in that district.

SHUSHANNA continues to be the mecca of prospectors in Alaska, and men are coming out with excellent reports. Supplies are reported still to be scarce, but as the McCarthy trail has been put into condition for use, ample food and material for the winter's work will doubtless be on the ground soon. The discoveries are really on the Chisina, a tributary to the Tanana that might well be considered the upper Tanana itself. Rich gravel has undoubtedly been found. Whether there are present the old gravels that gave stability to other Alaskan placer districts has not yet been announced. It is possible,

too, that glacialiation may have interfered with the extent of the district, but information available is too indefinite as yet to warrant a positive opinion, and we may hope that the misnamed Shushanna is really another of the great placer districts such as have brought romance and industry to the Far North.

PERSISTENCE or non-persistence of ore deposits in depth is a subject of unceasing interest to geologists and mining engineers. One of the most interesting sessions of the International Geological Congress recently held at Toronto was devoted to the discussion of this topic and related phases of ore deposition. Papers were presented by Messrs. J. F. Kemp, Malcolm MacLaren, W. H. Emmons, Paul Krusch, L. L. Fermor, and Paul F. Fanning. Among those participating in the discussion were Messrs. G. F. Becker, Waldemar Lindgren, A. C. Lawson, F. L. Ransome, A. C. Lane, H. V. Winchell, T. T. Read, J. A. Udden, and many others. Considerable difference of opinion developed, particularly in regard to the limitations of secondary enrichment. As Mr. Lindgren noted, Mr. Krusch and Mr. L. C. Graton have come to diametrically opposed conclusions as regards the secondary origin of bornite, and it is evident that a complete consensus of opinion lies still far in the future. We print this week a brief discussion of the general topic, prepared by Mr. H. V. Winchell, but not presented, Mr. Winchell preferring to speak instead, which he did, clearly and forcibly. In later numbers we shall present abstracts of the formal papers presented, as they tie on well to the discussion that has been running in the *Mining and Scientific Press* in the last two years especially.

LODE MINING in the interior of Alaska has made slow progress, which is not especially surprising when account is taken of the lack of transportation and other difficulties incident to pioneer work. Just what these are, and how they are being overcome, may be judged from the account of the Willow Creek district, written by Mr. Sumner S. Smith. Well informed Alaskans look upon this as one of the most promising areas for lode development in the North. It is a region in which the great mass of quartz diorite cuts through the later sedimentaries, and, as suggested by experience in California and southeastern Alaska, the conditions are especially favorable for development of large orebodies. So far only the small high-grade veins have attracted attention. It is to be hoped that with improved conditions mining on a larger scale may prove possible. One announcement of the summer bears upon this directly. It will be remembered that the Alaska Central railroad extending northward from Seward to Turnagain Arm is hampered by heavy grades and curvature which have been recognized as a serious obstacle to converting it into the proposed trunk line to the interior. When it was built, the advantages of Seward as a harbor and townsite and the supposed prohibitive cost of tunneling at Portage pass, influenced the location of the line. Re-examination of the pass this summer has shown that it affords a feasible route for a railway, and that a much shorter tunnel than was anticipated is all that will be necessary. Details of the survey have not

been published, but it is known that an entirely new face is put upon the matter and that a short workable line to the Susitna valley is possible. Sentiment in favor of government building of Alaskan railways seems to be consolidating rapidly, and when Congress can be induced to act, a large and valuable country will be opened to mining.

SLAG LOSSES in copper smelting have been a fruitful theme for discussion, the question as to whether the copper was present in the slag as mechanically entrained matte, or had been oxidized, thus forming a true if undesired component of the slag, having important bearing on practice. Mechanically held matte particles may be caused to settle, while the copper which has been oxidized is practically beyond recovery. Mr. Lewis T. Wright has contributed valuable evidence and a more recent study of Mr. Thomas Kiddie gives confirmatory results. Where care is taken to give the matte ample opportunity to settle from a not too viscous slag the amount of copper present as sulphide is found to be small, any increase in copper content being due to the presence of an increased amount of oxidized copper. If this rule holds good with converter slag, as there is reason to believe it does, the practice at many plants of returning fluid converter slag to the reverberatory furnaces partakes of the nature of a solemn futility, and the growing tendency toward pouring converter slag directly into the settler of the blast-furnace is in the right line of progress. The settler retrieves the mechanically held matte and the blast-furnace slag so dilutes the content in oxidized copper that the feelings of the management will not be injured at the thought of its going over the slag dump. As a matter of fact there is no economic difference between rejecting a large quantity of slag of an apparently low average and a small quantity of comparatively high content.

The Passing of La Lucette

Mines, like Hamlet's dog, have their day; which comes to an end at last in pinched-out veins, lower grade of ore, influx of water, or one or several of the thousand and one ills which may cut down a promising prospect in its adolescence or write *finis* to the record of production of a well known mine. So closes the day of La Lucette, which though a comparatively small mine, was yet one of the most notable of them all. Since 1889 it has been the leading producer of antimony, and in 1910 was reported to yield one-quarter of the world's production. Curiously enough, the mine was worked for antimony for nearly fifteen years before the presence of gold was discovered. During recent years, of the gross output, about \$800,000 per annum, about two-thirds of the value has been derived from gold and one-third from the antimony produced.

The mine La Lucette is at Genest, about eight miles from Laval, France, in the department of Mayenne. Here steeply inclined veins occur in a region of quartzites and slates, of upper Silurian and lower Devonian age. The veins consist of rather wide bodies of quartz in which occur narrow rich streaks of stibnite and pyrite. The mining concession, which

covers 841 hectares, was obtained in 1889 by La Société anonyme des Mines de la Lucette, and for many years the sulphide streaks were mined and the antimony recovered, the quartz which was broken incidental to mining the sulphides having been used for road metal and other industrial purposes. In 1903, M. Strap, now general manager of the prosperous gold mine, La Bellière, at St. Pierre-Montlimard, Main et Loire, discovered the presence of gold in the quartz, and a new company, with a capital of 3,150,000 francs, was formed in 1904 to undertake the recovery of gold, its operations meeting with such success that in 1909 dividends of nearly 45 per cent upon the issued capital were paid. Two veins were worked, the larger of these being an example of that beau idéal of the prospector, a vein which grows larger and wider in depth. Unfortunately this condition was not persistent, and recent work discloses the fact that at about 700 feet in depth the vein passes out of the more brittle rocks into shales and quickly disappears in a network of stringers. The shale is of great thickness, and the possibility of finding the vein again on the farther side is remote in the extreme. The mine has some years of life, until the veins are exhausted down to the shale horizon, but its final end is definitely in sight. France still has notable gold mines, such as La Bellière, Le Chatelêt, and others, but the passing of La Lucette is much to be regretted. Incidentally, a large producer of antimony will cease to yield, and a larger demand for the output of the numerous other producers will result. But from antimony regulus to babbitt metal is a long step, and it is not to be expected that axes, the world around, will squeak in lamentation.

Prospecting by the Government

Finding new mines is becoming increasingly difficult as the shoots which outcrop at the surface are located and mined. The world needs and will continue to need additional metal, and there can be no doubt that the crust of the earth contains enough metal to supply the needs of mankind, but how to find it is a problem. Doubtless much remains to be done in the prospecting of additional territory by old methods, but also new methods must be developed. On another page the problem is discussed thoughtfully by Mr. Albert Burch, whose extended experience through the West and the identification of whose interest with the West, makes his proposals especially significant. We think well of the plan he outlines, though we recognize the many difficulties in the way of its adoption. For the United States Geological Survey to begin prospecting the public lands would be but the natural extension of its present duty to classify the public lands. We have long felt that the next great task for the Geological Survey was to develop the methods of scientific prospecting, and unless it attempts, and at least in part succeeds in pointing the way here, it will miss a great opportunity and fail to meet a legitimate task. The application of the methods may be by public or private agency, or by the two in competition, as Mr. Burch suggests. That is a distinct problem to be solved on its merits, but the time is rapidly approaching when, in the United States at least, it will not be

possible to meet the demand for metal by relying on the efforts of the man, however hardworking, who has merely a 'hunch.' Administration of any such system as Mr. Burch proposes would be full of difficulties and would call for talent of a high order, but it is not an impossible task. As illustrating the difficulties to be met, the situation in the Wyoming oil-fields at present may be cited. Prospecting here is under way at the same time that a party is in the field for the Survey, classifying the land. Friction, intense enough to have generated some heat, has resulted. It is clearly impossible for the Department to announce in advance of the investigation what lands will be withdrawn, and the officials have been reluctant to issue a general blanket order and so stop all prospecting. As a result, the oil men do not know where to turn. To start for a district means but to attract the attention of the geologists to it and place a premium on its withdrawal. Here, as in other matters of controversy in regard to the public lands, the element of uncertainty is one which promotes much ill feeling. It is not possible to avoid all of this until Congress, acting for the whole people, adopts a definite policy, but it is possible to have a policy that is definite and sharp and under which rights may be certain.

As to the form that government aid to mining should take, there is much room for difference of opinion, and we think it would be helpful to have further discussion of Mr. Burch's proposals, which have the merit of being concrete as well as thoughtful. We believe that Western miners would not object to a small royalty if they could be certain of value received in return. If the Government can really aid in finding a mine, the man who works it is not going to refuse to pay a moderate return. In most instances he does that now, only he often pays to one who has contributed no real service. It must be recognized that much prospecting, however scientific, will prove of no avail, and that many campaigns will result in loss. The experience of the Ontario Bureau of Mines is a case in point. No one familiar with the excellent work of Mr. W. G. Miller and his associates, can question the high quality of their skill. When the Provincial mine was reserved, opinion was unanimous as to its value. Indeed, there were loud protests at the reservation of the tract. When the mine proved of less value than was anticipated, the outsiders protested that it was the natural result of 'inefficient' governmental work. When it was thrown open to lease, it was bid off at a price that, in the light of later events, proved much too high. To this day no satisfactory answer has been given the question of why the Cobalt veins are not found in the area to the south, where, by all the apparent rules of geology, they should be present. Failure, therefore, must be anticipated in many cases, however careful the preparation for success. Failure, however, stares us in the face along the road we now travel. The world needs and must have more metal. Sooner or later the wise men of the profession must point the way to its finding. The men of the Geological Survey have the best chance to lead in this great work. Will they accept the responsibility?

Persistence of Ore Deposits in Depth

By HORACE V. WINCHELL

Like every question whose answer depends on the definition of a term that is relative, the impulsive reply to this one will reflect the temperament of the individual conducting the discussion. A person of sanguine temperament, just about to invest in the development of a mining prospect or with a nicely engraved stock certificate in his strong box, will have visions of an ever-widening vein of precious metal ore extending downward indefinitely and becoming constantly richer as it approaches the centre of the earth. Men of much experience, having perhaps tried for years to find an ore deposit that does 'persist' far enough to make a mine, will declare with emphasis that there are none such. Many geologists even, not accustomed to carry on researches beneath the surface of the ground, and without much consideration of this question, are likely to entertain the idea that, since it is necessary to dig in the earth for ores, they may extend downward as far as digging operations can be conducted. And, on the other hand, the geologist who broadly compares the depth of mines with the thickness of the earth, and who has greater familiarity underground, will perhaps say that ore deposits do not and cannot persist. And it must be admitted that all of these opinions, contradictory as they are, have a certain amount of truth, depending on the point of view.

Depth of Ore

Ore deposits do persist; but there are depths below which they do not and cannot extend. Some of them are bonanzas, increasing in size and richness (down for long distances) as depth is gained; mining operations are in some instances being conducted at the depth of more than one mile from the surface, and the bottom is not yet. Still, it is unquestionably true that numerically the majority of ore deposits do not carry 'pay ore' below the depth of 1000 ft., and a very large percentage, numerically, are worked out before attaining the depth of 500 ft. The western half of this continent is dotted all over with holes in the ground where ore was found and mined near the surface, and where great hopes were aroused and extensive preparations made for large mining operations, but where the ore did not persist. On the other hand, some veins are still productive at 3500 or even 5000 feet.

No profound thought is needed to suggest that the behavior of ore deposits as to persistence depends largely on their origin. It is an undoubted fact that there is a class of ores which have been formed through the agency of surface waters. It is perfectly obvious that such ore deposits cannot persist below the depth to which surface waters can penetrate and still be active. In general, therefore, deposits of oxides, carbonates, and chlorides do not persist below the vadose zone or belt of free circulation of ground-water.

It has further come to be admitted that many sulphide ores are formed by the reactions which take place between descending solutions carrying oxidized

products from the upper portions of veins and the unaltered sulphide minerals situated at greater depth. It is even true that the richest portions of many ore deposits, and often the only parts rich enough to be worked profitably, are the portions thus secondarily enriched. And it is perfectly obvious that such mines can persist no deeper than the agents which induced the secondary enrichment.

Oxidized Minerals and Secondary Sulphides

The depth to which oxidized minerals and secondary sulphides can be carried and deposited depends on a number of factors, such as time, character of the enclosing or overlying rocks, and their porosity or permeability, climatic conditions, underground temperature, and the chemical activity conditioned thereby. Thus, where, as in the Lake Superior region, the rocks have been exposed to weathering and decay for geologic ages, enormous deposits of iron ores may be formed, the oxidation reaching downward for many hundreds of feet. And no one knows how much has been removed by glacial erosion. Here the time element has been paramount. But in this same extensive glaciated region, where a relatively cool climate has prevailed for ages; and where the rocks have not been so rapidly and deeply rotted, there are few important deposits of secondary sulphide ores. Such ores are indeed present, but occur very near the surface. South of the border of the continental ice sheet, however, where the rocks are rotted to greater depths, and where chemical activity is more intense, important deposits of secondary ores, formed in much shorter periods of time than have been available in the Lake Superior region, are found.

Influence of Climate

In regions of rapid erosion and youthful topography, oxidation and secondary sulphide enrichment do not extend so deep as in the vicinity of the arid plains and plateaus. Of course, the possibility of changes in climate, drainage, and many other geological conditions must always be kept in mind; but it is true as a general fact that there are fewer secondary ore deposits, whether sulphides or oxidation compounds, in those regions north of the margin of the continental ice sheet, and that their depth is not so great as in all the country farther south, extending far down into Mexico. It is also true that secondary ores play a less important rôle on the western slope of the Cascades and Sierra Nevadas (where rain and snow fall are heavy and erosion more rapid than oxidation) than upon the drier eastern slopes and foothills. The actual depth of such secondary ore deposition may vary from a few inches to two thousand feet; and under exceptional conditions, where faulting has been extensive and recent, or the rocks broadly uplifted and fissured, may be even deeper.

The factors which determine the persistence of primary ore deposits are not so easily determined.

Such ores are believed to have been formed by magmatic agency and to represent either actual magmas or chemical precipitates from vapors and solutions expressed out of the magmas.

As for the first category, ore magmas, although they may be expected to vary widely and rapidly in size, shape, position, and richness, there is no reason to anticipate their discontinuance short of the stock from which they were originally derived. Such ores are seldom sufficiently concentrated to be of commercial value, and except for certain iron and nickel ore deposits, are not likely to be found often in actual practice.

Conditions for Ore Deposition

The conditions which govern the maximum depth at which primary ores may be deposited by ascending waters, vapors, and gases are physical and chemical. There must be some way for the passage of the aqueous and gaseous solutions, and chemical reactions must transpire. Various estimates have been made as to the lowest point at which the smallest openings may exist in the rocks. It is reasonable to suppose that there is a limit below which the rocks are so dense as to be practically impermeable, but as yet sufficient data are not available to determine the effect of such enormous pressure and high temperatures. Whatever it may be, it is quite safe to assume that no large and valuable mines will ever be found there, because in the first place, of the physical impossibility of working to any such depth, and in the second place, because of the scarcity of ore at the initial points of its assemblage.

It is known that the solvent power of solutions rises with the increase of temperature and pressure, and that mere supersaturation compels precipitation. It is readily understood that if a saturated solution starts on its way toward the surface from the depth of 30,000 ft., it will be under less pressure and at a lower temperature at the depth of 20,000 ft.; and it is practically certain that at various points on its upward course it will become progressively supersaturated and thus obliged to part with a portion of its burden of mineral, the less soluble substances perhaps being deposited in the order of their solubility. Thus are found zones of minerals in the veins of certain districts, gold to a certain depth, copper beneath the gold, and zinc under the copper. At what depth these various chemical reactions take place because of supersaturation is not known. And if it were known, there are so many other factors involved, and so much unknown subsequent erosion that it would be impossible to make practical application in any given instance.

Precipitation

While supersaturation alone may bring about precipitation, it may also be induced by chemical reaction or the interchange of molecules between the solutions and the rocks through which they are passing. In this way the ores are formed by metasomatic replacement. But, here, too, the physical conditions must be such as to permit the passage of the solutions, otherwise there can be no chemical interaction. Stationary solutions soon reach a state of chemical equilibrium and may remain unchanged for ages. It is only moving solutions that deposit ores. And

again one is confronted by the presumption that below some such depth as six or ten miles, solutions, even if they exist and regardless of their nature, cannot and do not migrate.

Theorize about it as one may, when he comes right down to the consideration of concrete cases, it is found that no two mining districts have had precisely the same antecedents; nowhere have precisely the same factors contributed to the final result; hardly any two mines, even in the same district, are the same in all respects. There may be a general similarity of mineralization; but, even so, the gold and silver ratios will differ in different mines or different veins, or even in different ore-shoots in the same vein. Or there will be noticed in a single mining camp, minerals in one vein which occur much less abundantly, or not at all, in another. Or certain veins will be continuously mineralized while other veins, not only within the same district, but even within the same few acres of ground, will carry their ore only in lenses or shoots. The outcrop of one vein may still be covered by Tertiary lavas, while adjacent veins of similar mineralization may have been exposed to weathering, erosion, and secondary enrichment since the Triassic. Of one vein there may have been carried away by erosion a thousand feet or more. In another the ore may not come to the surface at any point, and there may never have been any of it removed by erosion.

What is really 'depth' for one vein or ore deposit as it is found today, may be nearly brought to the surface by erosion and earth movements; and there may be no way to compare it with other deposits of the same region but much more recent or different origin.

Relation of Depth to Value

Such considerations impel caution against the ever-imminent danger of generalization. And yet, it must be possible to generalize to some extent. Some experience has been had, some mines have been studied; it is known whether, as a matter of fact, ore deposits resemble wedges with the narrow edge up (or down). And candor compels us to admit that on the whole, mines are usually of lower grade and less productive in depth, almost without exception and without reference to their genesis (magmatic segregations alone excepted). It is not possible to specify closely the depth at which impoverishment begins, nor to predict the point of serious decline or ultimate demise of a mine. But this is because of our lack of understanding of its origin and history. I fully believe that the day will come when such forecasts can be made with a fair degree of confidence, although they will always be subject to correction by the possibility of faulting and duplication of ore or its enrichment through fissures which occur at greater depth and have not been developed at the time of examination.

In general, veins do become smaller and tighter with depth; mines are surely exhausted and worked out; old mining districts are abandoned and new ones discovered. Ores become baser, more complex, and less valuable. Free-milling ores, oxides, carbonates, and chlorides are conspicuous by their general absence below the depth of 2000 ft.; and although it

is possible to imagine their formation and to write the chemical equations expressing the theoretical mode of their formation in the deep, yet they are not found in minable quantity. That individual who, or mining company which goes on prospecting to much greater depth after the ore has, for a series of years, declined in value and quantity until it is too poor to pay, is in most cases throwing money away.

The future mining industry will consist more in the treatment of lower grade ores by more refined and economical methods and in the opening of ore deposits whose presence was not conspicuous on the surface and whose existence was consequently overlooked, than through the pursuit of veins by improved mechanical devices to much greater depths than are now attained. And in my humble opinion, the all-sufficient reason is because the great preponderance of ores is to be found within 3000 or 4000 ft. of the surface, with occasional instances of exceptionally large and strong fissures and intense and long continued and repeated mineralization, reaching downward to much greater depth.

Selective Flotation at Broken Hill

Owing mainly to the state of the metal markets, there has been manifest of late, in many ways a decided weakness in Broken Hill, New South Wales, stocks, but that weakness has not been nearly so pronounced as it would have been had it not become slowly recognized that the field was likely to benefit largely by the putting into operation of certain new treatment processes whereby the slime heaps that are so marked a feature of the district are to be made capable of remunerative treatment. The Zinc Corporation already has made complete trial of these new processes with most satisfactory results, there being as a consequence a considerable greater profit made than was made previously.

What, then, are the new processes? Their object is well described by a writer in the *Australian Mining Standard* who puts the position thus:

Minerals Separation

It was recognized that the Minerals Separation, and perhaps other processes, would recover the lead, zinc, and silver from the slime, leaving a clean worthless gangue, but it has been almost an impossibility to separate the lead and zinc slime concentrate into marketable products. The method used for attempting this is wet concentration of the mixed concentrate float on tables and vanners, taking advantage of the difference in specific gravity of galena and blende, the operation being known as 'de-leading.' By this means, an imperfect separation is effected, and the products, though in themselves probably not very suitable for smelting, can be mixed with the higher grade products obtained in the wet mill and zinc tailing mills, to form a marketable product. That this method does not give entire satisfaction is evidenced by the fact that all the mines along the line of lode have been experimenting with a view to finding a process to separate the lead and zinc in the slime concentrate more effectively. The processes that are being

evolved to effect this have been called selective or preferential flotation processes. One of them is already well known as Horwood's process, and consists in subjecting the concentrate to a sulphatizing roast by which the galena particles are coated with sulphate of lead, while the blende particles are unaffected. After roasting, the material is re-floated, the unaltered blende floating and the coated galena remaining behind.

Method of Control

The other processes—for there are several now under trial—seem to depend upon the control of the character of the flotation by the control of the aeration of the pulp, and the chemical composition of the solutions. How imperfect the slime treatment has hitherto been is shown by the fact that the Central (Sulphide Corporation), and the Broken Hill Proprietary had to cease the attempt to deal with the old slime dump with the plants they had erected for the purpose. Now there are several companies treating the current slime from the mills, and the results should soon be obvious. Selective flotation will effect a revolution in Broken Hill practice, making it advisable to create slime instead of to avoid sliming, because by this treatment the lead is recovered from the slime and the zinc is recovered in the form of a high-grade concentrate. On average slime this should be worth \$5 per ton. The South mine, with about 300,000 tons of accumulated slime, should benefit particularly, and the North will also, though in a lesser degree, find the advantage of the new methods, though this mine and the British have sold their old dumps to the Junction North. The directorate of this last-named Company has shown great foresight in the purchasing of the old dumps despite the Company's poor financial circumstances, and its plant will be available with but little alteration. The Proprietary company and the Amalgamated Zinc are busy stacking slime, and the latter Company will reap good profits. It is estimated that the net value of all Broken Hill ores will advance from 50c. to \$1 per ton on account of the wet mill slime alone. If so, the added value to the mines should be from \$5,000,000 to \$10,000,000, and also many low-grade ores will be made profitable to work.

Chromic iron ore produced and sold in the United States was nearly 70% greater in 1912 than in 1911, according to J. S. Diller, of the U. S. Geological Survey. The total output marketed was 201 long tons, valued at \$2753, compared with 120 tons valued at \$1629 in 1911. California is the only producing state, and the output comes from three separate deposits. Two new mines were opened, one near Livermore, in Alameda county, and the other near Piedra, in Fresno county.

The total production of lime in the United States in 1912 was 3,529,462 short tons, valued at \$13,970,114, as compared with 3,392,915 short tons, valued at \$13,689,054, in 1911, an increase of 136,547 short tons in quantity and \$281,060 in value. The total number of plants operating in 1912 was 1018, as compared with 1139 in 1911.

Lode Mining in the Willow Creek District

By SUMNER S. SMITH

The history of the Willow Creek district dates from the discovery of placer gold on Willow creek in 1898 and on Grubstake gulch, a small tributary, in 1899. As the source of the placer gold was shown to be the small lenses and veinlets in the schist which formed the major portion of the stream valleys, and as but little attention was given to lode mining at that date, the quartz veins were not discovered until 1905, when locations were made on the divide between Fishhook, a small tributary of the Little Susitna river and Willow creek, since

the mines have been developed to a point where conditions warrant the installation of a hydro-electric, a steam, or gas-producer plant in the lower valleys, it may be possible to double this period or even operate the entire year. The rainfall is not excessive and the summer climate most enjoyable.

Freight

The steamship companies have a sliding scale for the freight rates, but an average of \$16 per ton is charged from Seattle to Knik anchorage, \$6 from

KNIK, ALASKA.

ALASKA FREE GOLD MINING CO.

which time the limits of the district have been constantly expanding.

Situation of Mines

The district is about 35 miles northeast of Knik by wagon-road, and the mines which up to the present time have been proved profitable are situated on the divides between Craigie, a tributary of Willow, and Willow, and between Willow and Fishhook, a creek which flows southeast into the Little Susitna river. The sides of these valleys, which have been eroded by glacial action, are steep and precipitous and the bottoms covered with detritus and glacial wash. These conditions have led the prospectors to seek the upper slopes where the outcrops have been comparatively easy to trace and to avoid the lower levels, so the majority of properties discovered are high above timber line, the ore being sent over aerial trams several thousand feet to the mills in the valleys below.

Length of Season

There are practically two working seasons, the winter when the roads are covered with snow and in good condition for sledging, and the summer when the snow has melted. During the spring and fall the roads are almost impassable, and the snow blocks the trams and hinders the work at the mines. The actual season of mining and milling at the present time does not exceed four or five months and covers a period from some time in May till the latter part of September or October. At some future date, when

the anchorage to Knik, and \$1 wharfage. From Knik to the mines the present winter contract price is 4c. per pound, and in the summer double that figure. Probably these figures could be cut down a little now, as the Alaska Road Commission has constructed a first-class wagon-road to the centre of the district. There is comparatively little grade from Knik to where the road crosses the Little Susitna river at Mile 28, from which point there is a continual ascent to the mines, with one hard pull of about a half mile. The road is excellent for hauling in winter and summer, but, as mentioned before, almost impassable in the spring and fall.

Labor

Miners are paid at the rate of \$3.50 per day and board, an estimated cost of \$1.50 per day for board being made by the mine operators where the crew averages 20 to 30 men. The shortness of the season and the fact that this time of the year is the most favorable for prospecting, make it hard to assemble an efficient force of men. Living conditions are severe. Hurried tent camps are erected in the spring which give but little protection from the mosquitoes and moose flies, and are disagreeable in wet weather. This condition should change rapidly as the mines develop, but at the present time it is but little inducement for a man to pack his blankets 35 miles for a job.

Systems of Veins

The country rock is a quartz diorite intrusive in a

mica schist and there are three sets or systems of veins: (1) those in the diorite striking almost at right angles to the schist-diorite contact; (2) those apparently parallel to the contact but in the diorite; and (3) those in the schist striking at right angles to the contact. The present mines of proved value are in the first class, though some excellent prospects have been opened on the second and third types. The diorite is blocky and the fissures seem to traverse it for great lengths, with small cross-fissures coming in from both hanging and foot-walls. The quartz is usually accompanied with a small amount of gouge on both walls, and is from white to a bluish tinge, with reddish streaks due to the oxidation of the iron minerals. While many specimens show free gold the greater portion of the gold seems to be finely divided and not visible in the ordinary hand

two sets of plates and is passed to two Wilfley tables, being finally impounded for future treatment. Power for the plant is furnished by a 10-in. turbine under a 30-ft. head, though a 35-hp. boiler and 25-hp. engine have been brought to the camp to supplement this when the water is low.

Alaska Gold Quartz Mining Co.

On the property of the Alaska Gold Quartz Mining Co., which joins the Alaska Free Gold on the north, two veins, the Independence and the Granite Mountain, have been opened. Both strike northwest. The former averages $21\frac{1}{2}$ ft. in width and dips 38 to 42° southwest, while the latter averages 18 inches wide with a parallel strike, but a lower dip, about 16 to 17° southwest. On the lower vein a drift has been driven about 350 ft. and stopes al-

TRAM TERMINAL, ALASKA GOLD QUARTZ MINING CO.

ALASKA GOLD QUARTZ MINING CO.

specimen, though it is rare to find a piece that will not 'pan' colors. The veins in the diorite vary from a few inches to a few feet in width, strike northwest and southeast, and dip toward southwest.

Mines

At the property of the Alaska Free Gold Mining Co., on Fishhook creek the main vein has been traced the length of several claims by open cuts and on the northeastern portion of the outcrop a drift is being driven that will give approximately 150 ft. of 'backs'. At this point an aerial jigback tram has been erected which carries the ore 1100 ft. in a single span to an intermediate ore-bin from which point it is carried by a similar tram 2500 ft. to the mill, the total drop from mine to mill being 800 ft. A third tram with a 2250-ft. span has been installed from an open cut on the southern portion of the property to the mill. Two 500-lb. buckets are operated on these trams, the loaded pulling the empty back. Track cables are $\frac{5}{8}$ in. diameter with $\frac{1}{4}$ -in. haulage cables. At the mill the ore is crushed by a jaw crusher to one inch when it is fed automatically to a Lane slow speed mill 10 ft. in diameter making 8 revolutions per minute. No screens are used, the size of the product being governed by the height of the discharge which is kept about $6\frac{1}{2}$ in. above the die and the amount of water fed to the mill. Inside amalgamation is practised with excellent results. From the mill the tailing is split over

ternate with pillars. On the upper vein 110 ft. above the lower level a drift has been driven 100 ft., opening an intermediate level, and 90 ft. above a cross-cut has been made and raises driven to the vein. From these openings 236 tons was sent to the mill in 1911, and 680 in 1912. The ore is conveyed from the mine to the mill over an aerial jigback tram, $\frac{5}{8}$ -in. cable being used for the track, and $\frac{1}{4}$ -in. for the haulage. From the jaw crusher the ore is fed to three 350-lb. stamps and one Nissen stamp. The small stamps drop 7 inches 104 times per minute and crush to a 40 mesh. The Nissen stamp drops 6 inches 96 times per minute and crushes to a 40 mesh. From the stamps the pulp flows over plates to the concentrating tables, after which the tailing is impounded for future treatment. Power for the plant is furnished by a Pelton wheel under a 110-ft. head. One ton of concentrate with an approximate value of \$450 is obtained from 75 to 100 tons of ore.

The Gold Bullion Mine

The Gold Bullion mine, which was discovered about a year after the two former properties, is situated near the top of the divide between Craigie and Willow creeks, and shows outcrops on both sides of the mountain. The property has a record of production of over \$130,000 since 1910, though but little work has been done toward its development as a mine. At several points where rich outcrops were opened, cuts were run or stopes driven to get out the

easy ore which stoped about two feet in width. In 1907 a 2-stamp mill was erected, and in 1911 five stamps were added to this. The ore is transferred from the mine by two aerial jigback trams, the distance from the mine to the transfer bin being 1300 ft., and from the transfer bin to the mill 3800 ft. The drop between the mine and mill is approximately 1500 ft. In the mill, the ore is crushed to 50 mesh, the pulp going over plates to a Wilfley table. The property has recently been taken over by new interests and work started to determine the amount of ore available for the mill, which will be rebuilt at a later date.

Available Power and Timber

As the mines are all well above timberline, and as the melting snow furnishes power for only a short time in the summer, the question of timber and power is a serious one. Lignite coal outcrops on the south bank of the Little Susitna directly opposite the mouth of Fishhook creek, and a better grade could be obtained from the Matanuska field with an additional transmission line of about fifteen miles. This would offer a supply of power that would be available the entire year, or a hydro-electric plant could be installed on the Little Susitna which would furnish all the power necessary in the district. Excellent timber for all mine timbers or lumber can be obtained in the valley of the Little Susitna, though the expense of getting it to the mines will always be heavy.

Conclusions

As the mines of this district were discovered and opened by comparatively poor men, they have been forced to pay their own way, and if some of the mining has been crude it has been due to the fact that the properties had to be produced from the start rather than to the desire of the men who operated them. The veins are small but high-grade, and the ores easy to treat. The fissures have been traced on the surface for considerable distances and the shoots proved at least several hundred feet in length. Lack of any secondary enrichment in the present openings suggests that the ores will retain their value to the depth of profitable mining. From the known properties now in operation and the prospects under development, it would seem that with additional capital available for increased development, with permanent camps established so work may be advanced throughout the year, and with increased power facilities for mining and milling, the district should be assured of a steady growth and a substantial future.

Petroleum in the Philippines

*The existence of petroleum seeps on Bondoc peninsula, Tayabas Province, became generally known soon after the American occupation of the Philippines, although no mention of petroleum in Tayabas appears in the geological and mining publications of the former Spanish government. Within the past few years a number of companies have been organized and claims have been located far

and wide throughout the region, but development has not gone further than the drilling of two shallow wells. Each of these developed oil, but neither yields a quantity great enough to class it as successful. However, the wells are close together and neither is more than 325 ft. deep. This vicinity might be made to yield oil in commercial quantities under proper treatment, although it probably could not be considered the most favorable from a geological standpoint. That the wells were not successful therefore, fails as evidence upon which to condemn the whole field.

Over the southern half of the oilfield the land rises from the coast to a relatively high, level, or rolling plateau with deeply-incised narrow valleys. The highest member of the geologic formation is a thick bedded to massive limestone. A provisional scheme of the stratigraphy of the Bondoc peninsula is as follows:

Character of formation.	Thickness in metres.
Clay, sand, and gravel.....	0 to 10
Raised coral reefs, beaches, etc.....	0 " 15
Coralline to sandy limestone.....	20 " 50
Bedded sandstone, calcareous, yellow to brown, and locally concretionary	150 " 300
Limestone with coarse quartz, sand, and pebbles	0 " 15
Blue to gray, massive, clayey sandstone.....	50 " 100
Volcanic agglomerate (not generally distributed in the district, and occurring at two different horizons)	?
Massive bluish to brownish black shale (Bacau)	50 to 100
Gray, yellow, and brown, thin bedded sandy shale and sandstone (Vigo) ...	1000 + base not exposed
The oil horizon is in the two latter formations.	

Bondoc Peninsula

The presence of petroleum on Bondoc peninsula is indicated by seeps of gas and oil at widely separated points throughout the region. The seeps occur invariably near the crests of anticlinal folds and always at about the horizon of the Bacau shale. In several instances the oil oozes directly from the Bacau shale, but in at least one case it appears to come from the upper Vigo shale. Gas, unaccompanied by oil, is emitted at a number of places. No discoloration of the strata by the escaping petroleum can be detected, but the odor of light oil is noticeable in the neighborhood of a petroleum seep. The wells which have been drilled obtained their oil from the Bacau shale. The petroleum contains an unusually large percentage of light oils. Its specific gravity averages 0.832, and distillation gave 30.4% gasoline, 50.9% kerosene, 15.1% heavy oil, these by volume, and 3.6% residue by weight.

The existence of petroleum on Bondoc peninsula is established, although the quantity which may be available is undetermined. If no petroleum exists other than the small quantity which occurs in the Bacau shale, commercial production is not likely to develop, but if the unexposed lower Vigo strata also contain oil, the prospect is bright. The character of the Vigo shale (alternating shale and sandstone) is favorable for the accumulation of any oil that may be present.

Under the circumstances Bondoc peninsula must be classed as an unproved oilfield where there is a good chance of obtaining petroleum economically.

*Abstract from Press Bulletin No. 17, Bureau of Science, Government of the Philippine Islands.

Diamond-Drilling at the Poderosa Mine

By C. L. SEVERY

The Poderosa mine is among the rounded peaks that rise above and bound the western edge of the great Bolivian plateau, and lies only a few miles from the international boundary between Chile and Bolivia. The elevation at the collar of the main shaft is 15,400 ft. above the level of the sea. In any other country but South America this would be considered a mine of extreme altitude, but in this country of high elevations it calls for no particular comment outside of the fact that until quite recently the highest railroad in the world was the branch line to this mine.

The Ore Deposits

The ore deposit is copper of extreme richness, carrying from 6 to 8 oz. of silver throughout. The copper content runs from 8 to 65% over considerable widths. The vein is a true fissure vein in a massive dacite with a diorite dike as the hanging wall. In places this dike forms the hanging wall of the vein, but not throughout its full length. The vein is divided into two parts, the Poderosa, or principal part, and the San Carlos. The San Carlos is separated from the Poderosa by a fault with a vertical thrust of 150 ft., and a side thrust of from 50 ft. on the upper levels to 100 ft. on the lowest level. No indications of the veins in this district are visible upon the surface, most of which is covered with sharp angular gravel to depths varying from a few feet to over sixty feet. There are numerous side branches and parallel veins from the main vein, and it was to prospect for the continuance of these and to find the main vein at depth that diamond-drilling was started here in November 1910.

Three drills were put to work underground, an electric, an air machine, and a hand-power drill. The two former were made by the Sullivan Machinery Co., and the last by an English firm. The capacities were 500, 800, and 100 ft., respectively. 'E' rods were used in all, making a $\frac{7}{8}$ -in. core. In setting the bits here it was found best to use the method of setting 'kickers,' due to the rough character of the ground. Six stones were set in the face of the bit, three inside and three outside. The outside stones were set close into the side of the bit, and below these were set two smaller stones or large sized chips, called 'kickers,' directly opposite each other, to carry the gauge of the hole. This lessened the work on the large outside stones and gave less chance for breakage or pulling out a stone in a caving hole.

Conditions Attending Drilling

The conditions attending diamond-drilling here were difficult. The ground was bad for drilling, being broken and caving, and in places extremely hard but always remaining badly fissured. The veins were in a soft gangue material, for the most part, and would only give core with a double-tube core-barrel, and anyone familiar with diamond-drilling knows what a frail piece of apparatus is an 'E' double tube. Thus great care had to be taken in

using it. Cementing and casing the holes had invariably to be resorted to, which is not only expensive but causes much delay.

Another difficulty and inconvenience was experienced from breakdowns. Any break of a serious nature had to be repaired on the coast, a distance of 465 kilometres, and took from a month to six weeks before the drill was working again. Besides, the work done was of an inferior character.

During the calendar year of 1911 sixteen holes were drilled, two of which were unfinished. The deepest of these was 301 ft., and with the exception of six, all were flat holes prospecting laterally. The total combined footage of the sixteen holes for the year was 2444 ft., three-fourths of which was run with the electric drill. At no time were all three drills working at the same time, due to the shortage of runners. Native helpers, after a year's apprenticeship, were tried as runners, but they were a failure. They could learn the routine work, but when it came to knowing what kind of ground they were running through, and what the drill was doing, from the sound of the rods, or whether the bit was water-blocked, they failed to learn, which often resulted in heavy breakage of stones. Of the sixteen holes, one was an inclined surface hole and afforded more difficulties than any other. Near the surface the rock was even more broken and contained more waterways, so that the hole was continually losing its water and had to be cemented.

Cost of Operation

In any work of this kind, one of the most valuable and interesting points to engineers is the cost. In comparing these costs with other diamond-drilling figures, one must bear in mind the extra expense incurred in traveling expenses, high cost of supplies and labor, and all the other elements that have to be contended with in a country difficult to live and work in and so far from the base of supplies. Even considering all these items, the cost compares favorably with diamond-drilling in some parts of the United States. Like a great many other costs, especially in mining, they have to be taken with a great deal of consideration and weighed for what they are worth, before any comparison can be made with similar work elsewhere. Conditions are so variable and the personal element so great that any actual comparisons are difficult, to say the least.

The causes of the high costs may be summed up as follows. First, the higher salaries paid to skilled runners and setters operating in a foreign field, and their traveling expenses to and from the States, which amounted to an average of \$600 gold for each round trip per man. Second, poor diamonds. Of course there is a great deal of luck in buying black diamonds, as some look good and wear poorly, while others appear to be poor and wear amazingly well. And being a long way from the market, one has to accept what is sent him and do the best he can with them. Third, the abnormal cost of power. At so

high an altitude the combustion of fuels is poorer and the compression of air is a difficult and expensive problem, due to the light air. Also the fuel to produce the power is high, coal varying in price from \$25 to \$35 per ton placed at the mine. Fourth, delays are an important item. One can readily see the expense incurred by a delay caused by a part of a machine breaking which has to be cast at a foundry some three hundred miles away, and which takes at least a month to manufacture and about twice to three times that long to get from stock in the States, even when cabled for. Such delays are not only expensive, but aggravating in the extreme. Fifth, the poor inefficient native labor for helpers. Sixth, a formation which is extremely difficult for the operation of diamond-drills, namely, a hard fragmented wall rock and veins of ore either quite friable or in a soft gangue material. This means a heavy loss in diamonds while drilling through the rock and a poor representation of what is being passed through when in a vein.

Delay					
Total					

Time Setting Bits _____ Runner _____

ASSAYS

From	To	Character of Rock	% Cu.	From	To	% Cu.

Remarks _____

The average cost per foot in American gold taken over a period of a year for all three machines was \$9.05. During this time the electric drill made the best showing, due in part to the greater footage drilled, but only in part, as electric power costs less to generate than compressed air. The average cost for the electric power was \$8.63 per foot, for the hand power \$9.40, and for the compressed air \$11.40. The lowest cost per foot of drilling was \$3.40 on a flat hole with the electric drill, and the most expensive was on an angle hole from the surface of 39° dip, also with the electric drill, which cost \$13.65 per foot. Accurate check was kept on the loss of diamonds for each hole, and the diamonds were all weighed at the end of each month for the monthly cost sheets.

Report Forms

For keeping a record of the holes there was devised a system of report blanks, which vary in some particulars from others, but it is better to arrange one's own reports to suit the immediate conditions. The illustration shows the form of daily report for each shift. This sheet gives the time consumed in the various operations of drilling, the delay, time setting bits, feet drilled, feet reamed, length of core, besides the various changes in the character of the rock, assays of the core, if in ore, and of the cuttings. From the daily data the monthly sheets were com-

piled and also those for each hole were segregated. Cuttings were taken of every five feet of hole, except where it was positively known that the region was barren rock. In the vicinity of veins or while passing through them, cuttings were taken every foot, and a sample was cut at any time where the return water or action of the rods indicated a change of formation. Samples of the cuttings were taken by letting the water from the hole run into a settling box. One could generally count on the cutting assays being a little high on account of some of the lighter material not settling and being carried over into the sump. All the ground drilled on this property was of such a broken character that a high percentage of core was impossible with any reasonable amount of speed. In the soft vein materials on the lower levels a double-tube core-barrel had to be used to save any core at all. An average of 52% of core was saved, which is admittedly quite low. The average speed of actual drilling taken from the records over a period of a year, not counting time consumed in pulling rods, was 1.14 ft. per hour, and the loss in diamonds amounted to one-thirty-second of a carat per foot. This last statement indicates the difficult ground drilled during the operations in this district better than any other information which I might give.

A Dewatering Wheel for Pulp

*At the Winona stamp-mill, Michigan, it was necessary to re-use the water, and the tailing had therefore to be separated from it. This led to the development of the 12-ft. diameter wheel now in use. As shown by the drawing, the dewatering

ELEVATIONS OF DEWATERING WHEEL.

wheel consists of a sheet steel water-tight wheel with radial partitions along the periphery forming pockets in which the sand is caught and lifted out of the water and discharged at the top of the wheel over an apron upon the belt conveyor. The sand is run from settling tanks through spigots into the bottom of the wheel. The water overflowing from the wheel is carried to the settling tanks and re-used.

A refinery consisting of about 30 stills, 20 of which will produce motor spirit, is being erected at Casper, Wyoming, by the Standard Oil Co. The plant will probably be ready for work early in 1914.

*Abstract from a paper, 'Winona Stamp-Mill,' by R. B. Seeber, prepared for Lake Superior Mining Institute.

An Electric Mine-Signal System

By E. A. COLBURN, Jr.

Every mine doing a large amount of hoisting through a shaft should be equipped with some system of signaling and station lighting other than the old fashioned bell-pulls and candles. Electricity has been developed to such a point that its use in this service has resulted in many safe, efficient,

and turnsheets on the stations are eaten away in a few months.

When electric signals and lights were first installed in the mine the separate wire system was used. This system caused so much trouble from short circuits and wires being eaten entirely through by the acid mine water, that a cable made especially for the purpose and containing five wires, two for power and three for signaling, was substituted. Since that time little trouble has been experienced except on the stations where the wires are exposed to the drip from the timbers.

The cable is cut at each level and run into a junction-box placed at a convenient point on the station, and is protected from moisture as much as possible, decay usually starting at the bend caused by bringing the cable into the level. From the junction-box the wires are run to their respective lights and switches.

Station Lights

Each station is lighted by four or more 60-watt carbon lamps screwed into waterproof sockets and is equipped with three pull-switches, one for each compartment and one for the skip tender's signal or flash. The pull-switches, at each shaft compartment, ring their respective bells on the engineer's platform, but the skip-tender's pull-switch operates the buzzers on every level in the mine and one on the surface within hearing of the hoistman.

This signal is for the purpose of notifying the skip-tender when any level is without empty cars or when some one wishes to move from level to level. A pull-switch attached to this circuit is also within reach of the hoisting engineer for use in calling for repeat signals, etc. Bells were originally used on all the levels on this circuit, but were later abandoned on account of their large first cost and frequent repair due to the presence of so much water. Small buzzers are now used in series with 100-watt carbon lamps and are giving good service.

Although the pull-switches are constructed especially for this class of work and are made as nearly water-tight as possible, a little trouble has been experienced on account of water being drawn by capillary attraction up the stem of the switch and corroding the interior. The bells used on the hoisting circuits are large single-stroke gongs using 110 to 120-volt alternating current, the same as the rest of the system, and have been in use about ten years without giving any trouble. In case the power should be interrupted, ordinary bell cords, hung in the hoisting compartments, are used; as is also the case when examining the shaft between levels. By reference to the diagram, furnished by C. A. Bliley, mine electrician, connections may be readily understood.

The total production of coal in Oklahoma in 1912, according to E. W. Parker, of the U. S. Geological Survey, was 3,675,418 short tons, having a value at the mines of \$7,867,331. These statistics have been compiled in coöperation with the State Geological Survey.

Coal used in Pittsburgh amounts to 22,700,000 tons per year.

DIAGRAM SHOWING METHOD OF WIRING.

and reliable installations, one of which, at the Ajax mine, Victor, Colorado, is worthy of description.

The mine is opened by a 3-compartment shaft 1200 ft. deep, and at certain seasons of the year is exceedingly wet, due entirely to surface drainage. As this surface water is acid, after passing the first or second level, a great deal of trouble is experienced with any metal work placed in the shaft. Lag screws in the guides, nails in ladders,

Common Sense of the Fume Question

By HERBERT LANG

In spite of all that has been said and written during recent years concerning the cause and effects of smelter fume, it does not appear that correct ideas of the matter have yet pervaded the popular mind, which remains very much in need of enlightenment. On every side it is asked, "Why don't the smelting people do something to prevent damage by their smoke?" It is also common to hear apparently intelligent persons proclaim the great rewards that would accrue to the man who first solves the smelter-smoke problem. Inventors, too, in great numbers, continually put forth plans to abate an evil whose character and extent they have yet to learn. Proposals for the abatement of the nuisance are without number, although for the most part they are merely repetitions of what has been suggested ever since the time when furnaces first came into existence. The commonest proposal is the oft-recurring scheme of drenching the smoke with water, a plan which, for aught I know, may have originated in the time of the Pharaohs. It is surprising indeed that a scheme so frequently tried and so inadequate should not have been finally dropped long ago. It is, therefore, worth while to repeat what has been said a thousand times before as to the nature of smelter smoke, so as to get an idea of the problem to be solved, and then discuss it in the simplest language, so that there may be no excuse for the ignorance which impels men and newspapers to misstate facts, and legislators, like simpletons, to father bills requiring the impossible to be done.

Harmful Gases

In the first place, nineteen-twentieths of the gaseous material of smelter smoke is like that from an ordinary fire, and quite harmless. The remaining one-twentieth may consist wholly or partly of gases that under some circumstances, but not by any means all, may do harm to vegetation, and perhaps to animals. The really injurious gas, and practically the only part of the smoke which need be considered in any ordinary discussion of the question, is SO_2 , the gas which is produced by the burning of a sulphur match or a piece of brimstone. This is derived from the sulphide minerals treated in practically all smelting and roasting operations having to do with the extraction of copper and lead, as well as of gold and silver. This gas, as well as many others of a less noxious character, has to be allowed to pass off into the air in nearly every case, for reasons which will later appear. Although there are other solid substances in the fume, such as lead and various compounds of arsenic, which might be supposed to be injurious to organic life, they are for the most part withdrawn from the smoke and retained within the works by well known and universally employed apparatus, such as dust-chambers, bag-filters, and the like, with which all modern smelting plants are provided. Some of these are too valuable to be allowed to escape, and while some damage might be caused by their presence in the atmosphere the harm

actually caused is negligible in almost every case. The flue-dust, which is normally present in furnace gases of all kinds, is regularly caught, and therefore no harm need be apprehended from it, whatever its composition may be.

Sulphur Trioxide

Another gas, sulphur trioxide, SO_3 , closely related to the first, is disguised. It quickly takes up moisture from the atmosphere and becomes sulphuric acid, the destructive effects of which upon organic matter are well known. Since sulphur dioxide is also, to some degree, converted by natural processes into sulphuric acid by the action of free oxygen, the effects of the two oxides cannot well be differentiated, nor need they be in this connection. However, since the acid can be effectually removed from the air in which it is suspended, it presents some points of difference in its behavior from the dioxide, which is practically impossible to condense on any great scale, such as would be demanded by an attempt to purify the smoke of an ordinary smelting plant. A number of recent inventions fully adapted to the disposal of the recoverable part of the fume, especially of the sulphur trioxide, have been installed at the more modern plants. Unfortunately these improvements have been put forward in some cases as cure-alls for all the evils, though it is natural enough that emphasis should be laid upon successful work in this line, while the failure of attempts to render the really troublesome part, the dioxide, harmless, have been ignored so far as possible. But the public on its part is even more blameworthy. Noting the helpless condition of the smelters, a class of despicable blackmailers has grown up, who levy tribute on the industry, assisted by indiscriminating laws, and the profession of smoke-farming has attained quite a vogue.

Smoke-Farmers

A smoke-farmer is an agriculturist who makes two spears of grass grow in place of one, so that if they providentially wither he may get paid for both. By tying a sick horse in the path of smelter smoke he makes the price of two good horses when the poor beast expires. A barren ranch in the region of smoke is worth more than a fertile one in any other locality. Smelter smoke is the stock in trade of this sort of farmer, but any kind of smoke is a good excuse for extortion. The emanations of oil-refineries, gas works, or any other factory, so long as it rises in the region of smelters, answers the purpose so long as ignorant jurors can be convinced of the fearful effects of the flue gases. That these evils are enormously exaggerated there is no doubt. It is so common to hear tales of the desolation wrought by smelter smoke that the general public looks upon it as a matter of course that smelters almost ruin the country. If half a dozen trees and a clump of worthless brush can be shown to have been blighted, the greatest cry goes up and threats of suits and in-

junctions are heard. Litigation out of all proportion to the damage done takes place and heavy costs are incurred. One company alone in California has expended, in fighting suits for smoke damage, more than the actual provable damage by smelter smoke since the industry first began on the Pacific coast. Considering the kind of country where the smelters are generally situated, the character of the vegetation and the sparseness of the population, the conclusion is inevitable that most allegations of damage are all but baseless; and that in more distinctly agricultural regions the damage might be justly assessed at moderate sums. But it is useless to talk of justice or moderation. Public sentiment is, without sufficient reason, opposed to smelters, and jurors and court officers are only too ready to mulct them heavily whenever there is opportunity. They are looked upon almost as public enemies, and their operations are regarded as a public nuisance.

Unpleasant Nature of the Fume

Besides the foregoing consideration, there is another of some moment, which is rarely mentioned, even in the complaints of the smoke-farmers. This is the unpleasant nature of smelter fume, the smell of which is objectionable to many, though not at all poisonous. Residents of the neighborhood may well complain of this feature, which may render life less desirable. Sulphur oxides affect the breathing apparatus more or less, according to the degree of their dilution. Asthmatic people are apt to suffer from comparatively mild fumes, but healthy individuals, like the workers around furnaces, may enjoy robust health continuously, though exposed to much stronger sulphur emanations. It is found that the system, becoming habituated to such fumes, can tolerate, after a time, a gas which it would be difficult to breathe at first. It is rare indeed that smelter employees are heard to express objection to the atmosphere which their employment compels them oftentimes to breathe. Having settled that sulphur dioxide is the really objectionable component of smelter smoke, the source, as it were, of the woes both of those who make and those who breathe the fumes, it will be proper at this point to describe this body, tell its effects upon organic life, and explain the reasons why attempts to prevent or control it have been and must always be unsuccessful.

Sulphur Dioxide

Sulphur dioxide, as is well known, is a colorless and invisible gas, much heavier than air, that mixes with and diffuses itself in air readily, so that the fumes progressively grow weaker after they leave the smokestack and enter the surrounding air. The dioxide consequently becomes more dilute, but covers a greater space—two facts that must be kept in mind in this consideration. The mischief caused depends upon the strength of the gas and upon the time of exposure to its action. Gases containing not more than one-thousandth part of the dioxide may be breathed by man and are not greatly harmful to plants, and not by any means to all plants, since some are more susceptible to its influence than others. Again, when the air-currents move fitfully, now in one direction, now in another,

those plants which are affected may recover when the winds change their direction. I have seen bushes lose their leaves as many as three times in a season, putting forth fresh foliage whenever the smoke took a different course. But if the fumes persist over an area for a prolonged period, several months, for example, the plants are unable to recover, in many cases. This condition is not, however, so common as may be thought. In reality, but comparatively few of the trees and grasses within reach of smelter smoke are completely killed, and of those which expire, the character is such that little actual loss accrues. The native scrub growth within the smoke area of, for example, Shasta county in this state, is of extremely small value, except possibly in connection with the retention of the rainfall. It is certainly not worthy of governmental interference for its protection.

Smoke Dispersion

Very dilute fume, made so by the dispersion of the smoke by the trade winds, affects the crops little or not at all. In the natural course of things the volume of smoke broadens out as it drifts along, and while remaining suspended in the air troubles no one. The most favorable condition of things exists when the furnaces are situated on large plains. In this case smoke dispersion is unimpeded, but as most smelters are found in mountainous districts, where local air-currents, or still worse, stagnant patches of air exist, the smoke may have to take a definite direction and may be for some time protected from diffusion, and considerable damage may result. In fact, the greatest damage occurs in just such wind-bound areas; the more so as the fume becomes cooled nearly to the temperature of the surrounding land and hence is prevented from rising above the plant growth. It should be said that the initial heat of the gases, which adds to their ascensive force, is a factor. It will, therefore, readily be seen that in order to escape the fume difficulty, the smoke should be hot when it leaves the stack, and that the works should preferably be situated on a plain. If in a hilly country, the smoke should be conducted through culverts of sufficient lengths to the top of some eminence, where the general oceanic breezes may have free access. This has not been the practice, the custom being to place the plant, not where it will do the least hurt, but where it will do the most good.

Manufacture of Sulphuric Acid

The most obvious means by which the smelter-smoke nuisance is to be prevented is by retaining the dioxide within the works. This has been done, but so far only by turning it into sulphuric acid; a process which involves great expense, and is only admissible where a market exists for the acid. As a general thing, it would cost, aside from the value of the sulphur, \$6 to \$8 per ton to manufacture the acid (66°B.), corresponding to a cost of about 1c. per pound of sulphur in the ore. As applied to the prevailing copper ore of the Shasta belt, for instance, the average expense would be perhaps \$7 per ton, which is decidedly prohibitive. Few

copper ores could stand such a charge, and smelters are consequently debarred from the employment of this means of getting rid of their sulphur. But where a market can be found for the acid, the presence of the sulphur, otherwise a detriment, becomes beneficial, and sometimes highly profitable. It is in this manner, by the use of sulphur-bearing ores of various metals, especially of iron, that a large part of the acid of commerce is manufactured. In nearly all of the mining districts of this country, however, there is no market whatever for the acid, and even in so large a community as Butte the smelters have never had any encouragement to go into its manufacture. A small proportion of the sulphide ores of California are utilized in this way, and the greater part of the local output of acid, which reaches some 200 tons per day, requiring one-third that weight of sulphur, is made in this way.

Utilization of Sulphur

But the amount of sulphide smelted is so large that the sulphur contained in them is vastly greater than that needed for the acid manufacture. Indeed, it is probable that, taking one year with another, not more than one-fourth of the sulphur in California ores is utilized. The rest escapes into the air, furnishing the basis of what is called the fume nuisance. No one regrets this waste more than do the smelters, and they are fully alive to the desirability of conserving all valuable material and of abolishing the nuisance. But the situation, as it stands now, is clearly beyond them, and will remain so until either the excess of sulphide ores is used up, or population and manufactures overtake the mining business, producing a market capable of taking care of the vast quantity of acid which would have to be made. This, in a nutshell, has been the reason for the existence of the fume question. Since sulphur in the form of brimstone is worth in the centres of commerce about \$20 per ton, and in the form of pyrite about \$12, there is ample incentive on the part of the miners and smelters to do their best to improve conditions. The public should realize, what they do not seem to have grasped as yet, that the matter is a most difficult one, without the easy solution that the uninitiated appear to believe in. There are other methods of solving the question than acid production, but they have not yet passed beyond the experimental stage. What they are, I will briefly recount.

Methods of Recovery

The methods in general use are two. In the one, it is proposed to preserve the sulphur from oxidation during the treatment, causing it to pass off, sublimed and invisible, to be condensed farther on into flowers of sulphur, a merchantable commodity. This implies the simultaneous oxidation of the combined metals in the sulphides, which is a necessary part of the process. In the second method, the sulphur, oxidized in the process, as is the associated metal, is subjected to deoxidation after it has passed off, and is thus converted into the elemental form, settling likewise in the flues beyond. The Hall process, previously described in these columns, deals

with the sulphides in roasting apparatus, and consists in effecting their decomposition there by means of gases containing a paucity of oxygen; in short, enough to unite only with the iron, which thereby rejects its sulphur, which, at the heat prevailing there (some 1700°F.) is sublimed and passes over into condensing apparatus of no special kind. Thus the oxidized metals are procured, and with them, not the sulphur dioxide which is the universal concomitant of ordinary roasting, but elemental sulphur instead. The reactions are assisted by steam, which, as I have pointed out,* has the effect, at comparatively high temperatures, of decomposing metallic sulphides, with the evolution of hydrogen sulphide. This gas is by an easy decomposition the source of elemental sulphur, since by its interaction with sulphur dioxide that substance, together with water, is directly produced. The Hall process is about to be introduced on a working scale at the Balaklala mine, in Shasta county, in this state.

Separation of Elemental Sulphur

The idea of expelling the sulphur from metallic sulphides in the uncombined form is quite as applicable in smelting as in roasting. The underlying idea is the oxidation of the iron without that of the sulphur, which necessitates a selective action of the oxygen present. The oxygen, one would suppose, must be free, as in blast-furnace smelting; but this does not agree fully with the views of the proponents of the Hall process, who place reliance upon that combined with matters which, at the temperatures judged advisable, would give it up to the iron. Evidently there must be a sharp control of the gaseous matters, both before and after the oxidation. I designed and partly constructed, some eight years since, a plant to operate upon what I call ultra-pyritic principles, having in view the expulsion of the sulphur in the elemental form. In order to confine the oxidation to the heavy metals (almost exclusively iron) in the charge, I arranged for a very strong blast of five pounds per square inch, to be heated to a higher temperature (1000 to 1200°F.) than has ever been used in pyritic work. This I assume to be necessary to provide sufficient heat in the zone of fusion to carry on the reactions properly, not calling upon the sulphur for any increment of heat. This selective action of the oxygen under some circumstances is a common phenomenon, as may be seen in the quantities of sublimed sulphur accumulating upon roast heaps, and further, is seen in blowing converter charges when a good deal of sulphur is sublimed as such. In the ordinary pyritic process, much is also given off. We are apt to ascribe these appearances to the excess of sulphur in the mineral pyrite; but pyrrhotite, which contains no excess, produces also a volatilization of sulphur under the same circumstances. There is no doubt a great deal of promise in this direction, although it will probably be somewhat difficult to control the work so as always to get the best results. The combination of oxidation with distillation, which these methods practically are, must inevitably introduce complications hitherto unsuspected. I believe, though, that the principles

*'Metallurgy,' Vol. I, pp. 172-174.

are well worth following up. It would be surprising, indeed, if pyritic smelting were to advance another step beyond what we have always considered its ultimate, the production of matte and sulphur dioxide. It is perhaps too much to hope that the whole of the sulphur beyond that needed for matte production should be evolved in the elementary form, thus removing entirely the fume nuisance: there must doubtless be a portion that would become oxidized; but if any considerable percentage can be so recovered, it will be a distinct triumph for metallurgists, and will add greatly to the profits of smelting. The conditions, however, for the recovery and sale of the sublimed material must be favorable, from which we must argue that such an improved method will be of comparatively restricted application. It would hardly be expected that all the sulphur should be recovered by either of these processes; but should the percentage of the dioxide be made to go below that found destructive to plant growth, the chief end will have been attained. There are, in fact, two points of view to be taken: the removal of the fume nuisance, and the recovery of the valuable element, which are coincident.

Other Dioxide Methods

The other methods deal with the dioxide as it issues from the furnace. It is proposed by some to decompose the gas by means of carbonaceous fuel (petroleum or coke) in the flues. A fire is kept burning there, the excess of carbon taking up the oxygen of the dioxide as it passes through, which is thereby reduced to the elemental form, settling beyond in the form of powder. This method is undergoing experimentation at Campo Seco. In such a process, more than an incomplete recovery of the contained sulphur could not be expected. A very common but always unsuccessful proposal is to remove the dioxide itself from the smoke by means of water, which dissolves it to a small extent. Innumerable suggestions and inventions have been made with this end in view. It is quite possible to abstract the dioxide in this way, but as it is only soluble to a limited extent, the process is balked by lack of water and by the great size and cost of the necessary apparatus, added to which there is no practicable means of getting rid of the charged liquid, which in itself would constitute a nuisance even greater than that it is proposed to obviate. The bad effects upon the streams thus polluted with so active a gas need no emphasis. All fish and other animal life would perish, and the farms along the banks would be affected at least as injuriously as if the smoke were allowed to escape at once into the atmosphere. It would probably be worse, as the tendency of the gas to escape slowly from solution would carry the SO_2 to quite remote and probably inhabited localities. As only about 1% of the gas by weight is taken up by ordinary exposure to ample water, the quantity of solution would be tremendous, considering the immense output of smoke from large works, and no river of less size than the Amazon would be sufficient to cope with it. Any such use of streams would be immediately enjoined, of course. As a whole, the proposal is entirely impracticable, and

only deserves mention here in order to show the mistaken ideas of the many inventors who are constantly re-introducing this scheme in a new or, often, in an old form.

Washing the Gases

Although the wholesale removal of the dioxide and the suppression of the smoke evil by washing the gases is impracticable and visionary, a certain modification of this method has achieved technical and, in a limited way, commercial success. In this the practice is to absorb the gas in water dripping downward through coke-filled or other towers, whereby a solution is obtained containing about 1% of dioxide by weight. This is filtered to free it from the flue-dust and other solids, and then is heated in closed vessels, whereby the gas, which is less soluble in hot than in cold water, is driven off, caught in other apparatus free from air, and is then compressed by machinery until it assumes the liquid form. It is then an article of commerce, although of very limited application. The only works engaged in this manufacture, to my knowledge, prepares about 1000 tons of the liquid dioxide each year, a quantity which could be made from 500 tons of sulphur, or from two to three times that weight of heavy sulphide ore like that of Shasta. The manufacture, therefore, cuts no figure in a discussion of the fume question, and is only pertinent as showing what could be done were the demand for the liquid dioxide much greater than it is now or is ever likely to be. It appears finally that unless some unlooked-for change takes place in the industrial world, whereby much larger quantities of sulphur or its products are demanded, things must go on practically as they now are, the smoke being discharged into the atmosphere, but with a gradually increasing utilization of the sulphur according to the growth of the population and the demand for sulphuric acid. Conservation of the sulphur, however desirable, is impracticable under most conditions, since its conservation demands that the ore deposits lie idle until that element can be better utilized. It is not to be expected that owners of mines will suffer them to lie idle in order to conserve a substance of only problematic value when they are in position to realize on the more immediately valuable metals which they possess. Meantime, the smelters are awake to the desirability of improvement and are making many costly and strenuous efforts to obviate the fume nuisance. So far as I can see, their best hope will be to improve conditions by the use of very extended flues and culverts by which the smoke may be conveyed to points where it can do little or no damage. It is very desirable now to do the utmost toward building up a public sentiment which will look with tolerance upon their efforts, and will be more disposed to await their outcome. I must say the whole outlook is not very hopeful.

Stamp-duty at the Talisman mill, New Zealand, averaged 4.27 tons per stamp day in 1912. The cyanide plant produced 52,589 oz. fine gold and 223,652 oz. fine silver, the recovery being 95.1 and 72%, respectively. Treatment costs averaged \$3.42 per ton.

Emerald Fields of Colombia

By F. P. GAMBA

The adjoining sketch map shows the geographical position of the emerald deposits of Colombia. Of these deposits, those at Muzo are the most important, not only for the size of the workings, but also for the quality of the stones found.

I believe that Somondoco was the first emerald mine to be worked by the Spaniards. Shortly after operations were commenced here Muzo was discovered and the Somondoco mines were abandoned and not reopened until recently.

The Muzo emerald is remarkable for its color and water. Emeralds from other mines, although as perfect as those from Muzo, always have a yellow nuance and a glassy lustre, while the Muzo emerald, in the finest varieties, is blue nuanced, and in its lustre is *gota de aceite* (drop of oil) as described locally. The geological formation of the Colombian emerald deposits is different from that of the emer-

SKETCH MAP OF EMERALD FIELDS.

ald deposits of other countries and furthermore the Muzo formation is quite different from the Somondoco, Guasagao, and others in Colombia.

The Muzo Deposits

I will summarize in a few words the most prominent features of the emerald mines of Muzo. The country rock is a black dolomitic schist, probably of the Jurassic age. The emerald-bearing formation is a network of stringers of quartz and calcite carrying some iron pyrite. Beautiful collection specimens are obtained from these veinlets.

The emeralds are found in pockets in the stringers in a matrix called *guarrucero* which is interesting in itself. This *guarrucero* is a powdery material, gray in color, and spotted with green composed of a mixture of the carbonates of calcium, cerium, and lithium. The stones are loose in the matrix.

Emeralds are found in the *guarrucero* in all sizes, qualities, and shapes, and in some cases they are found in a green viscous material which is called by the miners *esmeralda tierna* (child emerald). The

principal associate of the emerald is the parisite.

While this is the most common manner of occurrence the stones are also found intermixed with quartz and calcite in the veinlets and here they are adherent to the gangue material. In many cases they are found as incrustations in the black schist of the country rock.

Classification of Emeralds

The emerald was evidently the last deposited of the vein materials. I have seen splendid stones completely enclosing crystals of pyrite. The color of the gem ranges from white to the typical blue nuanced green and in lustre from that of quartz to the oily lustre which is characteristic of the Muzo emerald. The specific gravity of the stone is a function of the color. The emeralds at the mines are classified according to color, water (limpidity), lustre, and form. It is impossible to imagine the beauty of the crystals which are to be found in the deposits of Muzo and is to be regretted that the Colombian government has not established a special department in the National Museum in Bogotá for a collection of these minerals.

Open-cut methods are used in mining. The emerald formation is under a bed of barren material more than 100 metres thick. This barren material is hand-drilled and loosened by explosives. The loosened material is then washed away by water under pressure. Water for this purpose is stored in large reservoirs constructed at higher elevations than the workings in order to afford the necessary head. When a good formation is discovered special workers begin the work, first the cleaning and afterward the hand-picking of the stones, precautions being taken to guard against robbery. The stones are sorted and weighed at the mine and again in Bogotá before being packed for shipment to Europe. The only authentic information about the production of the mines of Muzo is to be found in a report by E. Lloyd Owen, published in the *Diario Oficial* (No. 12,330) in 1905.

A production covering eight months, under favorable operating conditions, was as follows: First class emeralds, 262,548 carats; second class, 467,600; third class, 22,700; and fourth class, 16,000. The value of this production was over \$768,920.

Governmental Control

The Colombian government controls all of the emerald deposits in the country, which is an important measure, for were it otherwise over-production would result and the value of the gem would depreciate. It has also proved good policy to destroy all of the low-grade emeralds produced. Plans have been completed for improving the equipment at Muzo which includes the fitting of the mines with drilling and shoveling machinery. I have concluded that all the emeralds found by the conquerors in Peru, Ecuador, and other Latin-American countries came from Colombia.

The quantity of coal shipped by rail and water to Pittsburgh and through Pittsburgh to points west in 1912 was 43,801,134 short tons, an increase of 4,160,226 tons over 1911.

Power-Plant at the Associated Mine, Kalgoorlie

By M. W. VON BERNEWITZ

The Associated plant includes six Babcock & Wilcox boilers and six Davey-Paxman water-tube boilers of 1299 and 1255 sq. ft. heating surface respectively, with a working pressure of 140 lb. Salmon gum, gimlet, black butt, oak, and mulga wood are used as fuel, and 3.5 lb. of water is evaporated per pound of fuel, at and from 212°F. The boilers are fed by

MIXED PRESSURE TURBINE.

a vertical compound weir feed pump, which is an extremely simple and efficient type.

Hoisting Plants

At Tetley's shaft there is an electric hoist with a fly-wheel generator, of the well known Ilgner system. The geared hoist consists of two conical drums, driven by a 215-b.hp. direct-current motor, which uses about 70-kw. on an ordinary load. Foot and air brakes are attached. The fly-wheel set consists of a 6.5-kw. exciter, 65-b.hp. motor, and 9-ton cast steel fly-wheel, and a 130-kw. generator, all on one shaft, and in the order given, revolving at 720 r.p.m. This set was devised for the purpose of equalizing the power consumed during hoisting, by the energy stored in the wheel. At the No. 3, 6, and 15 levels in the main, or Judd's shaft, ore-bins have been excavated, and at other levels temporary chutes have been fixed for filling the skips, which hold two tons of ore. The steam hoist at this shaft was installed some 13 years ago, and has been in commission ever since. The cylinders are 20 by 60 in. The pistons

have tail-rods. There are foot-brakes on the discs, also post-brakes, and steam reversing and clutch gear. The engine hoists 3 tons from 3000 feet.

The Engine-Room Equipment

The main air-compressor is a cross-compound, air and steam engine. The steam cylinders are 33 and 57 in. diam., and the air cylinders have diameters of 29 and 48 in., with a 60-in. stroke. The maximum speed is 40 r.p.m. The ordinary Corliss valve-gear is attached. The fly-wheel is 20 ft. diam. and weighs 22 tons. The working load is about 500 hp. for the mine and mill, but the plant is capable of developing 1000 hp. As an auxiliary, there is a Rand duplex air-compressor, with steam and air cylinders, 13 and 22 in. diam. This engine is rarely used. For driving four No. 8 and six No. 5 Krupp mills with conveyors and elevators, there is a horizontal cross-compound engine of 500-hp. capacity, but with an average load of 350 hp. The cylinders are 18 and 35 in. diam., with a 48-in. stroke. The fly-wheel is 18 ft. diam. and weighs 19 tons. It has 14 grooves for the driving ropes, and a speed of 60 r.p.m. There is an auxiliary lighting set, consisting of a vertical compound engine of 135 hp. with forced lubrication, running at 350 r.p.m., and driving, by a flexible coupling, a 3-phase, 25-cycle, 550-volt generator of 85-kw. capacity, with an exciter on the same shaft. This set supplies power for the electric hoist and is used to drive 12 motors in the plant, but its use will soon be discontinued. The condensing plant consists of a large surface condenser containing 33,000 ft. of $\frac{3}{4}$ -in. tubing, through which the circulating water is pumped by a 16-in. centrifugal pump driven at 450 r.p.m. by a vertical compound engine of 40 hp. The water is pumped to a cooling tower. The air-pump consists of a vertical 3-cylinder engine running at 115 r.p.m. The average vacuum is 25 in. The exhaust steam from all the engines is passed into oil-separators, and then to the low-pressure turbine.

The Turbo-Generator

The turbo-generator may be described as a mixed-pressure turbine, as live steam may be used if there is not enough exhaust from the other engines. It is a horizontal type turbine direct connected to a 750-kw., 3-phase, 50-cycle, 550-volt generator, with a speed of 3000 r.p.m. The whole machine is mounted on a single bed-plate, and is entirely automatic in its action. If there is more exhaust steam than is necessary to drive the turbine, the excess passes by an automatic valve to the condenser; if there is not sufficient exhaust steam, live steam is admitted at 140 lb. pressure by six automatic valves. The low-pressure steam averages from one to two pounds, and the vacuum 25 in. Forced lubrication, at 45 lb. pressure, is essential for the successful running of the machine. The governor and valveless oil-pump are worked by means of worm-gearing, the former of the ball and spring type, operating in oil, as seen in the foreground, and if there is not sufficient low-pressure steam, the speed is reduced, and the governor admits more steam in the following manner. The governor has an arm connected by a rod to a small piston valve, which admits oil at 45 lb. pressure, to a rotary valve, which is connected to a cam-shaft.

This shaft is geared to an arm which fully opens the main low-pressure steam valve, when the oil pressure causes the cam-shaft to revolve, and the high-pressure valves are opened, one at a time, as steam is needed. If the low-pressure supply is entirely cut off, the high-pressure valves open, according to the load. It will be seen that the oil does all this work, besides lubricating the three main bearings. In case the turbine goes too fast, there is an emergency governor. This operates when the speed is at 3360 r.p.m. Fitted to the turbine shaft is a weighted eccentric on the inside of the bearing casing, with a spring at the back, and when the above speed is reached the eccentric flies out somewhat and hits a trigger, which in turn, by a system of rods and weights, immediately shuts off both high and low-pressure steam, the exhaust steam then going to the condensor by a bypass, and the turbine slows down. As packing could not be used on the shaft at such a high speed, a water-seal is fitted at both ends of the turbine.

The switchboard is automatic in action. There are eight panels of enameled slate, five of which are connected by leads to the various groups of motors throughout the plant. One panel contains the generator and exciter switches, and the various meters; another has the Tirrill voltage regulator mounted; while the last panel is for the lighting. The current for the latter is passed through a 50-kw., 3-phase, oil-cooled transformer, which steps down the current from 550 to 110 volts. The method of driving everything by motors is quite satisfactory, and several long lines of shafting which required much attention have been dispensed with along with the services of fifteen men. Power costs average \$1 per ton of ore treated. There are 41 motors about the surface plant, and the following table gives details of them, and their duty:

No. of motors.....	Capacity of each, hp.	Speed, r.p.m.....	Operation.	Power absorbed by each motor, hp..
1	85	720	No. 7½ Gates crusher.....	16 to 60
1	20	720	Incline belt conveyor, 110 ft. long...	12
1	10	950	Horizontal belt conveyor, 75 ft. long	5½
1	10	950	Fan for ball-mills	6
2	7½	950	Feed conveyors for furnaces.....	4
4	10	950	Four Edwards roasting furnaces...	6½
1	7½	950	Furnace discharge conveyor	4
1	10	950	Hot water pump for furnaces.....	7
1	7½	950	Assay office sample room.....	...
2	25	720	Hot ore conveyors, elevators, mixers.	12
5	40	720	Twenty grinding pans	20
1	10	950	Clean-up barrel and pan.....	...
1	20	720	Fitting shop machines.....	...
1	7½	950	Plate-rolls, shears, and punch.....	...
2	25	720	Centrifugal pumps, 5-in. delivery...	12
3	25	720	Six A. Z. agitators.....	16
1	40	720	Filter-press filling pump	24
1	20	720	Filter-press washing pump	15
1	10	950	Pumping gold solution to clarifier..	8
1	10	950	Residue mixer of vortex type.....	6
2	25	720	Residue belt conveyor to mixer....	12
1	20	720	Residue pump from mixer to pond..	12

Besides the above, there are several other motors on intermittent work.

Fineness of Gold at Fairbanks, Alaska

Placer gold is generally believed to increase in fineness the farther it is removed from its source or parent vein, an assumption based on field evidence. According to Philip S. Smith, in *Economic Geology*, interesting data on this subject has been supplied by Frank W. Hawkins, formerly of Fairbanks, Alaska. The placer gold having the highest fineness in this district assays 950 per 1000 parts, and is found on claims in the central part of the valley of Big Eldorado, a tributary of Goldstream. The lowest fineness recorded for any considerable amount of placer gold is 800, from claims near the head of Ester creek and on St. Patrick creek. L. M. Prindle and F. J. Katz have reported a fineness of 792.5 from Ready Bullion creek. The average of 167 determinations at Fairbanks is 880 fine, but the mean of two averages, according to the amounts of gold of each fineness, is 868.5 fine. The average silver is 127 fine. A comparison of the fineness of the bullion from the individual placer claims in the district indicates that, on the whole, the gold becomes progressively finer downstream. This fact is well illustrated by the bullion from Twin and Pedro creeks, for, at the farthest claim upstream it is 861 fine and becomes progressively finer downstream until at the junction of Pedro and Gilmore creeks it is 906 fine. No lodes are being developed in the Pedro Creek basin, but disseminated mineralization undoubtedly occurs there, so that the placer gold in this basin probably did not come solely from the lode deposits noted on the upper part of Twin creek and Skoogy gulch. This condition also prevails in all the other valleys. The data therefore do not warrant computations based on the assumption that all the gold is derived from the same source.

Influence of Surface Processes

The fineness of the gold probably increases even in deposits which are not being transported; in other words, probably the longer gold is subjected to surface processes, other conditions being constant, the finer it becomes. Therefore, in two deposits alike in all features except those due to difference in age, the older contains gold of the higher fineness. Search among the records of the fineness of gold from Fairbanks for detailed evidence in support of this belief so far has proved unsuccessful.

Twenty-four determinations of the fineness of the lode gold from different parts of the Fairbanks region were obtained. The highest fineness is 843, the lowest is 780.5, and the average of the 24 determinations is 817, which is equivalent to a gold value of \$16.89 per ounce. The average lode gold is therefore 63 parts per 1000 lower than the average placer gold reported in this paper or 40 parts per 1000 lower than the fineness reported by Prindle and Katz. The amount of silver was determined in five of the assays of the lode gold bullion and ranged from 149 to 180 parts in 1000 parts of bullion, the average being 167.5. The average silver content of the bullion from all the lodes computed as the remainder obtained by subtracting the fineness of the gold from 990, is 174.5.

Combination Specific Gravity Bottle and Dilatometer

By C. A. BROWNE

*The sketch shows a specific gravity bottle and dilatometer, consisting of a narrow tubular body *B*, holding about 30 c.c., connected at the bottom with a graduated capillary tube *A*, and contracted at the top to an opening at *O*. The latter is made slightly funnel shaped and is carefully ground on its inner surface so as to receive the thermometer *T*, which is also ground above its scale so as to fit perfectly tight after insertion. The displacement of the thermometer is about 7 c.c., which leaves a capacity of about 23 c.c. for the instrument after stoppering.

The end of the capillary tube at *E* is ground and fitted to a small cap *C*. The scale, upon which the changes of volume are measured, is graduated so that 1 division equals 0.001 c.c.; by means of a magnifying glass, readings can be made to 0.0001 c.c. Capillary tubing is manufactured of uniform calibre,

so that the graduation can be made with accuracy.

A few weighings of the instrument, after filling with air-free distilled water to different points of the scale at different temperatures, are sufficient for constructing a table of water constants for each scale division and temperature. The ground-glass surfaces should be lightly coated with vaseline to prevent all possibility of loss from evaporation. The instrument, when filled with water and stoppered, should show no loss in weight after a week's standing. In making weighings the bottle may be placed in a support, or it may be attached to the hook of the balance beam by means of a loop of wire wound about the neck at *N*.

For determining specific gravities, the method of operation is the same as with an ordinary pycnometer. If it is desired to determine the specific gravities of a solution at different temperatures, one filling of the instrument and one weighing only are required. After filling the apparatus the meniscus in the capillary tube is adjusted by means of a thin, tightly-wound strip of filter-paper to a convenient position upon the scale, and the whole is weighed. The instrument is then placed in a constant-temperature chamber (such as an incubator) and as soon as the thermometer and meniscus readings remain constant the observations are noted. By raising or lowering the temperature and noting the changes in position of the meniscus, the specific gravities and coefficients of expansion or contraction may be readily calculated. The position of

the meniscus is easily affected by very slight changes in temperature, so that the instrument is best handled by placing it in a stoppered glass cylinder.

Recovery of Quicksilver From Ores

During the last two years inquiries have been made by the United States Geological Survey relative to methods of recovery, and quantitative data on the subject have become available for the first time. These data show the insignificant total output from retorts, although a large number of retorts usually are in operation.

Quicksilver retort furnaces are of two types: the pipe retort and the D retort. Both work on the principle of distilling off the mercury from the ore separately from the gases of combustion and conveying the volatilized metal through short outside condensing pipes to a trough in which the mercury is collected. The retorts are built over fire-boxes and are filled and discharged horizontally from the same doors and from the furnace floor, the D retort by means of iron pans resting on the flat bottom and the pipe retort by semicircular shovels and hoes. Retort plants contain from 1 to 15 retorts, 12 being the usual number for a pipe-retort plant, and are inexpensive to build and operate. It has been estimated that a 12-pipe plant costs from \$1000 to \$1500, depending upon local conditions. The pipes themselves cost \$25 to \$35, whereas the D retorts about \$250 each. The D retort, however, increases capacity and decreases space. Recovery is probably 75% of metal in the ore as charged. Retort plants serve useful purposes at small mines or in prospecting or early development, but are best used perhaps for treatment of rich ore and concentrate or furnace soot. Unless carefully operated they menace the health of workmen by causing salivation; and when in operation at new mines the temptation is to gouge out rich ore for them and possibly quickly to sacrifice a property that otherwise might be remunerative.

The great bulk of present domestic output is from shaft furnaces, in which, as is well known, the descending ore meets the upward furnace flames and gases, and the volatilized metal passes with the gases and impurities of combustion into a series of condenser chambers, usually of brick, in which the metal is collected and from which it is drawn off. The gases pass from the final chamber to the stack, usually through an inclined flue. The modern tendency is toward the increased use of the Hüttner tile furnace perfected by Robert Scott, formerly of the New Almaden mine, which is adapted to both medium and fine ore. All the furnaces in Texas and Nevada are of this type. At New Idria, also, are the coarse ore furnaces designed by B. M. Newcombe, and at the Guadalupe are the Davey modified Litchfield furnaces. Some thought and experimentation have recently been given to the application of rotary furnaces for quicksilver ores. It has been estimated that a Scott furnace can be built, under favorable local conditions, at about \$1000 per ton of capacity. According to this the common 10-ton furnace should cost about \$10,000.

*From the *Journal* of the American Chemical Society.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Under-Estimating the Cost of Milling Plants

The Editor:

Sir—Under-estimating the cost of milling plants is the rule rather than the exception, and I have read with great interest Mr. Additon's diagnosis of the case. I cannot agree with all of his conclusions, however, and as it would appear futile to call attention to an ill without proposing a remedy, the following suggestions may prove of interest. The blame for under-estimating costs lies primarily with the buyer, who is, as a rule, aided and abetted in fooling himself by his mine superintendent. The latter is presumably a mining engineer, and is not unnaturally interested in holding his job. Therefore, when the question of building a mill arises, he will profess his ability to perform the duties of metallurgical engineer in devising a method of treatment, mechanical engineer in designing the plant, and engineering contractor in constructing it. It is truly a wise man who knows his own limitations, and a great man who has the courage to confess them. A mining engineer may know intimately everything from the collar of the shaft down; he may be able to call every rock known to geology by its first name, and yet be unable to calculate whether the chords of a roof truss should be 4 by 6 or 8 by 12. I have seen more atrocities in the form of mill plans submitted by mine superintendents than have emanated from any other source, and this is simply due to their efforts to *save* their employer's money by undertaking work for which they have had no special training. This lack of training along lines that are highly specialized becomes even more pronounced when the time arrives for the erection and construction of the plant. This work should under no circumstances be undertaken by the mine superintendent, but should be contracted for as a whole with a reputable contractor. I could cite countless instances within my own experience where mining companies have undertaken to do their own construction work in order to *save* the contractor's profit, with the result that their plants cost from 25 to 75% more than the contractor's bid, to say nothing of having taken a proportionately longer time to build. If a man who is his own lawyer has a fool for a client, what is the man who undertakes work that calls for the specialized knowledge of four different kinds of engineers? If you are ill, send for a doctor; if prison stares you in the face (save the mark!) send for a lawyer. If you desire to develop a mining property, send for a mining engineer. When you are ready for a reduction works, let a metallurgical engineer devise your treatment and a mechanical engineer design your plant. When you are ready to build, you have only to whistle, and the contractors will swarm around you by the score. This method of procedure has many advantages, chief of which is a knowledge of the

cost of your plant before it is built, rather than after. Men are human and prone to err, and engineers, like other men, make mistakes. But of all the engineering professions, the engineering contractor is the only one who pays for his. Remember this, and when you see an engineering contractor on the street, don't speak roughly to him. He is human like the rest of us. One word more. I quote: "Visiting in the city by the manager, superintendent, or engineer at company expense, discussing the proposed plant, and *lunching with machinery dealers* is a source of expense which could be eliminated." The italics are mine. I would like to ask, *en passant*, if when lunching with a machinery dealer Mr. Additon was ever so careless as to pay for his own lunch.

Josh Billings, one of the pioneers in the art of simplified spelling, once said, "Sum peepls branes is located in their heds." This may be true enough, but it is the common experience of machinery houses that the only direct route to a buyer's affections is by way of his stomach. I do not pretend to say that a 'mess of pottage' is the only factor that influences sales, but it would be indeed difficult to negotiate a sale without it. The mine superintendent is given to calling the machinery salesman a peddler in public, but is glad to consult with him in private. As a matter of fact, the machinery houses have for years made practically all of the mine superintendents' estimates for them gratis. Not only that, but this practice is often extended into supplying engineering data entirely outside of any possible chance for securing an order for machinery. Personally, I should like to see all machinery dealers shut down on this sort of thing. It could be done by mutual agreement. All reputable manufacturers would a thousand times rather figure from intelligently prepared drawings and specifications than make the extraordinary efforts they do at present to get at the buyer's requirements before selling machinery to meet them.

CHAS. T. HUTCHINSON.

San Francisco, August 16.

Prospecting by the Government

The Editor:

Sir—While traveling from one Nevada mining camp to another, a few days ago, I stopped at a spring, where I found a typical old-time prospector camped for the night. His equipment of tools, camp utensils, and food was good, and his four burros were grazing nearby. Everything was well cared for, and he gave me the impression of being a man who was in earnest and understood his business.

With all that, he told of having spent months in a southern range where the chances of finding mineral were almost hopeless; and he was then on his way to the north to search for a legendary vein of high-grade ore that had been found and later lost by his brother prospectors in the misty past.

He belongs to a class that is rapidly becoming extinct, and many reasons have been given for his disappearance from the hills; such as the establishment of forest reserves, the difficulty of interesting capital in mining, etc. It is my belief, however, that the real cause is the lack of incentive because

of the increasing difficulty of finding good mines. The veins which disclosed their presence by bold outcrops were located long ago, and more obscure veins in their immediate vicinity were soon added to the list of producing mines. Later, such districts as Tonopah, with only about 300 linear feet of outcrop for the entire district, and Goldfield with very little more, were discovered and developed. Their discovery caused an influx of 'prospectors' of all classes and degrees of experience, and Nevada was overrun by grocery clerks, schoolteachers, doctors, lawyers, miners, and a few prospectors. Some were searching the hills for bonanzas; some were watching the searchers, that they might be ready to stake a convenient townsite; and some, also, were lying by shady springs consuming their grubstakes.

The result of a decade of this kind of prospecting in Nevada has been the discovery of few first-class mines and the expenditure of a great deal of money on prospects, of varying merit, that have not made mines. On the whole, it has probably not resulted in finding enough profitable mines to repay 20% of its cost; and in this respect Nevada is in no worse position than the other mining states of the West. The chances for success in prospecting have been steadily diminishing for years, and herein lies the secret of the true prospector's withdrawal from the field. They have not all died, nor have they all become rich enough to retire.

It is a well known fact that Tonopah, one of the most important mining districts found in recent years in the United States, was discovered by accident; and, no doubt, similar accidents will occur in the future; but why leave such things largely to chance? The mining of precious metals in this country is an important industry, and a decline in the mining of the money metals must affect all other industries, but the decline must come unless new mines are found to take the place of those which are becoming exhausted.

Most of the land in which it is possible to find new mines is still a part of the public domain, and owned by the people as a whole. It is therefore suggested that it would be a proper function of the Government to systematically search its own lands for mineral-bearing veins, using all the knowledge gained from science and from the experience of trained prospectors.

Such work could be very properly performed under the direction of the Geological Survey, though only a comparatively small number of the force employed need be trained field geologists. Good prospectors are close observers, and with a good field geologist to aid in the interpretation of their observations, much good could probably be accomplished in the way of finding ore deposits whose existence might never be suspected by the average prospector, because of obscure outcrops or none at all. It would also be possible to eliminate much effort which is now expended in the exploration of geologically impossible regions.

Assuming the discovery of promising prospects by the government explorers, the question of what to do next with such discoveries is another problem. I am not one of those who believe that the Government should engage in mining or in any

other business that can be better handled by private capital; nor do I believe that the mines discovered by the use of public funds should be donated to individuals. However, the policy of leasing public lands, both mineral and non-mineral, seems to be growing in popular favor, and a system of leasing partly developed prospects could doubtless be devised.

One plan would be for the Government to first do enough development to show that certain prospects had merit. It could then publish a list of prospects with a brief description of each and call for bids; a long-time lease to be given to the responsible bidder who offers the highest royalty. Forfeiture should be provided in the event that the lessee should violate rules intended to safeguard the Government's interests, but no attempt will be made in this letter to formulate such rules.

As an objection to this plan, it might be urged that a salaried prospector would not have the same incentive to spur him to action as the prospector of the past, and this is doubtless true, notwithstanding the fact that excellent work is done by the employees of such Government departments as the Geological Survey, Bureau of Mines, Reclamation Service, and others. To attract and keep good men, it might be proper for the Government to offer its prospectors, in addition to moderate salaries, preference rights to lease at a low fixed royalty any promising ground found by them, or to participate in royalties received by the Government from others. This in effect would make the Government a colossal grubstaker on its own domain; but it would be grubstaking trained men instead of amateurs, and the results should be correspondingly better.

This plan need not exclude private individuals from exploring the public lands in search of minerals except that certain sections should be temporarily withdrawn from entry while being examined by the Government men.

Possibly the ideas outlined above will be of sufficient interest to others of your readers to induce criticism.

ALBERT BURCH.

San Francisco, July 10.

Drill Efficiency at Buckeye Belmont Mine

The following table is from the report of the superintendent, Letson Balliet:

Class of work.	Time, minutes.	Cost.	Time, per cent.
Setting up machines.....	82	\$0.82	17
Shifting machines	66	0.66	14
Changing steel	75	0.75	15
Morning and noon starting.....	24	0.24	5
Oiling and cleaning.....	15	0.15	3
Getting steel and water.....	15	0.15	3
Tearing down and blasting.....	45	0.45	9
Actual time drilling.....	158	4.80	34
Total, 8 hours, or.....	480	\$8.02	100

The gold belt in the James River basin, Virginia, covers an area of 700 square miles in Fluvanna, Goochland, Buckingham, Cumberland, Powhatan, and Amelia counties.

Special Correspondence

NEW YORK

THE COPPER SITUATION.—NEW SMELTER TO BE BUILT AT GLOBE.—RECOVERIES OF COPPER IN MIAMI, CHINO, AND RAY MILLS.—CAMP BIRD AND SANTA GERTRUDIS.—NEW DOMINION COPPER COMPANY.

The expectations of large profits from the upward movement of copper and copper shares seems to have been a trifle premature. Shares in copper mines have indeed advanced on the basis of increased earnings resulting from a higher price for copper, but the selling price of the metal exhibits a certain degree of balkiness that scarcely seems to presage any 'runaway market.' There are loud assertions that copper has sold at 16c. all during the week, but as a matter of fact very little has been sold, and the truth of the situation seems to be that with Mexico hollering over, the tariff still unsettled, and the outcome of banking and currency legislation still in the lap of fate, manufacturers have cut their buying orders down low and are pushing the selling end of their business so as to face the situation with as large cash assets as possible. European buyers continue to take copper in large quantities, exports for August being estimated as 80,000,000 lb. This is nearly 10,000,000 lb. in excess of the monthly average for this year, which is itself about 10,000,000 lb. greater than the monthly average of the past two years.

The foreign statistics continue to show decreases in the stocks of copper abroad. Consumers point to these two facts and intimate that, taken in connection with the fact that the financial situation in Europe has at times been worse than in this country, there are indications of trouble ahead. It has even been stated that the Amalgamated is shipping copper from foreign warehouses back to this

CHINO CONCENTRATOR.

country. It is evident that the domestic consumer is disposed to stand pat, in the belief that when he needs copper he will be able to get it at reasonable prices. When the official job of tinkering at Washington is at last completed, there is every reason to believe that business will at once pick up again. The new tariff will make necessary a good deal of readjustment, and it is but natural that trade should meet such a crisis on a conservative rather than an extended basis.

The building of a new copper smelter at Globe, by the International Smelting & Refining Co., prophesied in this column many months ago, has been confirmed by the officials of the International company. Work will begin in time to have the smelter ready to handle the concentrate from the Inspiration mill, and the Miami concentrate will be diverted to the same plant. Since the Amalgamated owns nearly half of the International shares, this new venture will increase its hold on the copper-smelting industry by nearly 90,000,000 lb. per year. J. Parke Channing was recently in New York, and in discussing the situation at Miami referred to the fact that the tailing losses in copper at the Miami mill are 0.8% copper. As a matter of fact they were somewhat less than this during 1912, according to the annual report, which shows a recovery

of 69.39% of the copper in a mill feed averaging 2.393% copper. As far as percentage goes, this compares well with such plants as Chino and Ray, where recoveries of 70% and 68.25% are being made. However, the Ray tailing only contains 0.5% copper, and the extra 6 lb. of copper in the Miami tailing represents nearly \$1 worth of metal per ton that escapes from the mill. It is stated that a 20-ton leaching plant will be constructed in the hope of recovering about 12 lb. copper per ton from the tailing. It will indeed be interesting to see the outcome of the experimental study of the two most promising methods for the reduction of tailing losses. The Inspiration will soon have a 600-ton oil-flotation plant at work, and comparison of the results there attained with the success of wet concentration followed by leaching at Miami will be of great importance in determining the lines along which milling will advance in the future. The Miami mill is now treating about 3000 tons per day, the mine output having been brought back to normal.

The Camp Bird, which like a hale old man, refuses to yield to the decay of old age, has been showing remarkable vitality lately. The Santa Gertrudis ore reserves on June 30 were estimated at 778,000 tons, worth \$3,740,000, as compared with 586,000 tons, worth \$4,390,000, the year before, and the shares went down in sympathy. But recent reports from London show that the July operating profit at the Santa Gertrudis was \$91,500, or at the rate of nearly 20% on the Gertrudis shares, and state that the cross-cut on No. 20 level has cut the vein, showing 5 ft. of ore worth \$20 per metric ton. Since in the estimates of ore reserves only 26,000 tons out of 269,000 was allowed as probable ore below No. 19 level, the discovery markedly improves the position of Santa Gertrudis, which is so closely allied with Camp Bird that the two move in sympathy. At the Esperanza, Ltd., 17,572 tons of ore and 34,229 tons of tailing was treated in April, May, and June, with a gross yield of \$333,590 and a net profit of \$83,339.

The New Dominion Copper Co., which is controlled by the British Columbia Copper Co., is about to make a peculiar payment. The Company started out as the Montreal & Boston Mining Co., and, after some troubles, was taken over by the Dominion Copper Co., Ltd., with a capital of \$5,000,000 and a bond issue, which was sold at 90, with an accompanying bonus of \$200 in stock. Three years later it was taken over for \$348,000 by the New Dominion company with \$1,250,000 in issued capital and \$500,000 in 6% convertible bonds. For the first time in its existence, the Company operated at a profit last year, with a net profit of \$119,000. It is now proposed to pay coupon No. 4 of the bond interest, due the first of next month. This is provided that the holders will be willing to forego payment on coupons No. 1, 2, and 3. Though not entirely out of the woods yet, the Company is certainly on the uphill road and deserves all the success it attains.

LONDON

CORNISH MINING AND DEVELOPMENTS AT THE DOLCOATH AND LEVANT.—RE-TREATING OLD TIN-ORE TAILING AND FURTHER EXTENSIVE DEVELOPMENT CERTAIN IN THIS INTERESTING WORK.

Cornish mining has been again to the fore in city circles during the last week or two. Attention has been attracted by the keen inquiry in Cornwall for Dolcoath shares, and the press and the public have been endeavoring to ascertain the cause. It is unfortunately, both in America and in England, a habit among most of the directorates of mining companies to refrain from issuing either good or bad news. In spite of the strenuous pleas put forward by *The Mining Magazine* and by the daily and weekly press, the shareholders continue to be left in the dark with regard to new discoveries and proposed modifications of policy. The Dolcoath coterie is not noted for communicativeness, and the public has to do a good deal of guessing when movements take place in the shares. As far as can be ascertained—and this is only hearsay—the improvement in the situation at Dolcoath is due to the intersection of the north lode at 1260 ft. depth, and the discovery there of rich deposits of tin ore. It is generally forgotten that

the Dolcoath area contains a series of lodes of which only one, called the Main lode, has been developed at all extensively during late years. The Main lode has been in poor ground recently at the bottom level, 3000 ft. below the surface, and it was deemed advisable to investigate the other resources of the property. The cross-cut was started over six months ago, and is much deeper than any previous workings in this part of the property, as recorded in the old plans. No doubt, at the forthcoming meeting of shareholders, some information will be given.

Another old Cornish company, the Levant, near Land's End, has attracted attention owing to the possibility of the present company having to relinquish possession at the expiration of the lease a year or so hence. This mine is famous owing to its workings penetrating a long way under the sea. It is also notable because it is the last of the big Cornish mines to be worked under the old cost-book system. Francis Oats, chairman of the De Beers Diamond Co., is the largest shareholder at present, and he is in fact the controller of its fortunes. The 'lords'

are demanding onerous terms for the renewal of the lease, asking for an increased royalty and requiring a large amount of money to be spent on development. One wonders whether it is the fact of a man connected with a mighty industry like the De Beers being in control at Levant that gives the 'lords' the opportunity of squeezing their lessees. Moreover, they state that other people are ready to come forward and accede to the new terms. Mr. Oats is unmoved by all these threats, and says he will not renew except on the old terms. For the last year or two he and the board have adopted the policy of accumulating a reserve fund with the object of embarking on a vigorous policy of development directly the renewal of the lease is agreed. If, however, the lease passes to other hands, this fund will be distributed, and the assets, such as plant, realized.

The re-treatment of old tailing is the most profitable business in Cornwall at present. The present vogue was set three years ago, when the Anglo-Australian group, of which J. T. Lempriere and W. L. Baillieu are leading spirits, purchased over a million tons of dump from the Carn Brea & Tincroft company. The average content of these dumps is nearly 20 lb. metallic tin per ton. The material is re-ground and re-treated on tables and buddles according to standard methods, but the recovery is only 40%. The reasons for this poor result, and similar results at other mines in the neighborhood, are being investigated by several engineers and metallurgists. The subject has been discussed in detail in *The Mining Magazine*. The Company is investigating several chemical processes for treatment of the material with a view to securing an adequate recovery, one of the processes being that invented by the manager, Arthur Richards. The same group has recently turned its attention to the accumulation of cassiterite in the sand of the Carnon river, one of the tributaries of Falmouth harbor, and coming down from the mining districts of Chasewater and St. Day. The stream itself is a small one and runs down the middle of a tidal estuary. Here natural concentration has been going on for ages. Many people have tried to treat this sand, but hitherto to no profit. The new owners have formed a company called

Carnon Valley (Cornwall), Limited, of which Theodore J. Hoover is chairman. Tests have been made, and above high tide 1,900,000 tons of material averaging 12½ lb. tin per ton has been proved. In the tidal portion there are also large amounts of material worth treating, but as the engineering problem is not easy, their exploitation will be left for a time.

Another sand deposit that promises well is on the Gwiltian beach at the mouth of the Red river, which comes down from the Camborne district. Here, David Stephens has made a decent living for a generation by regrounding and re-concentrating. The Cornish Tin Sands Co., of which Oliver Wethered is the leading spirit, has acquired the property and has erected a large regrounding and dressing plant. This should be in operation within two months.

HOUGHTON, MICHIGAN

THE STRIKE SITUATION IN THE COPPER DISTRICTS, GENERAL FEELING, AND THE ATTITUDE OF CERTAIN FOREIGN WORKMEN.

There is not much change in the strike situation here, although additional men are going to work every day and the mines are producing a little copper 'rock.' The socialistic element continues to dominate the situation, covertly under direction of prominent politicians who are trying to make capital out of conditions, and who are encouraging the strikers and officials of the Western Federation of Miners. This element seems to have pronounced influence with some of the politicians in high places, so much so that there is great indignation at the action. In fact, the independent business men of the copper country are now convinced that the strike would be over and the mines working normally if it were not for the moral support given the strikers and their leaders by the investigators and mediators sent here. This applies both to the state and federal governments.

There is no doubt that the majority of the workingmen of this district never wanted the strike, and did not countenance it when it was called. At the present time, a large majority desire to return to work and several thousand have already returned. But it has required a great deal of nerve and courage to go to work under existing circumstances. The situation now is, that practically all of the English and Scotch miners have resumed work. A large number of the Italian miners have signified their intention of returning to work during the week ended August 23. They claim that the situation was misrepresented to them, that they have not received strike benefits as promised, and that they can see nothing to be gained by remaining away from their employment any longer.

The two classes which are holding out for the Western Federation and a continuance of the strike, are the Finns and the Austrians. Most of them are rank socialists, particularly the former. The spirit of unrest and opposition to any organized government is born and bred in the Finn. It comes with him from his native land, and when he gets a home and a job in this country it is difficult for him to distinguish between license and liberty. The Finn socialist is against the government, no matter what the government may be. They are just as naturally opposed to authority, restraint, or power, and it does not matter much where that government or authority originates. There are two Finnish dailies and several weekly newspapers here. One of the dailies is avowedly socialistic, and its editors, managers, and employees are the leaders in this strike movement. The other Finnish daily has recently come out in favor of the strike, and that position has added to the general antagonism toward the Finns as a class, upon the part of the public that generally is hopeful for a return to normal conditions. In the recent dock strike in Duluth, operated by the Industrial Workers of the World, the Finns took a leading part, and orders have gone forth that henceforth no Finns are to be taken on the Duluth ore-docks. The general belief here is that, when this difficulty is ended, the number of Finns employed in the mines of Houghton county will be largely reduced.

To date the strike here has cost the workmen more than a million dollars in loss of wages. In some instances it has cost them their jobs, as the mining companies in resuming operations are diligently weeding out the more rabid of the agitators and socialists and refusing to take them back on any terms. They are showing preference for the better class of labor and are securing promises from all the men who return to work that they are going to keep away from affiliation with the Western Federation of Labor. These facts are becoming pretty well known throughout the country, and a general influx is anticipated in a short time. In fact, quite a few of the miners from the lead district of Missouri, where the Federation recently called a strike, have already arrived here and applied for work. A good number from this district, who went to Detroit to take jobs in the automobile factories, are inquiring about positions in the copper country again, as they anticipate a strike outbreak instigated by the Industrial Workers of the World in a short time.

DEADWOOD, SOUTH DAKOTA

NEW MILL FOR THE MOGUL MINING CO.—HEIDELBERG CLAIMS TO BE DEVELOPED BY DEADWOOD BUSINESS CLUB.—MINING AND MILLING AT THE TITANIC, IRONSIDES, NEW RELIANCE, BISMARCK, AND GOLDEN GATE.

Favorable progress is being made by the Mogul Mining Co. in the construction of its new plant in Nevada gulch, and it is hoped that the mill will be crushing ore by the

ment, using Dorr thickeners, and eliminating the filter-plant as used in the old mill. As the first plant in the Black Hills to use this process with a filter, its operations will be closely watched.

Promotion of a mine has been undertaken by the Deadwood Business Club, a committee of which spent over two months examining numerous properties. Upon the final report of the committee it was almost unanimously decided, at a general meeting of the members, to accept the proposition offered by the owners of the Heidelberg group, which was to give to the club a one-half interest in the property if the club would raise \$5000 for further development. This amount was quickly raised, from fifty men who agreed to advance \$100 each in monthly payments. The idea was not to raise the money among a few men, but to give a goodly number an opportunity to contribute, and have a good list of boosters for the enterprise. Work will commence September 1 and continue throughout the winter. The property is regarded as one of the best prospects in the Black Hills, showing a most encouraging face of ore in the meagre developments which have thus far been made. Sampling of this by numerous parties shows it to be of excellent milling grade, while some of it would pay well to ship to smelters. It is the intention of the club to develop the mine to a point where it can readily be sold, and it is believed that this can be done in six months time. The property is in a rough part of the country, and the first work will be the construction of a wagon-road, expected to cost about \$700.

OPEN-CUT MINING AT THE WASP NO. 2. PROPERTY.

end of the year. For over a year the Mogul has been without milling facilities, a fire having so severely damaged the plant at Pluma in March 1912 that the Company took no steps to rebuild on that site. After considerable research work, it was decided to rebuild at a point more convenient to the mine, and that near the Snowstorm mine was selected as the most convenient and suitable. A plant at this point will be able economically to handle a large tonnage of low-grade ore which could not profitably be shipped to Pluma. From the Pluma plant will be salvaged practically all of the crushing and grinding machinery necessary for the erection of the new plant, which will have a capacity of 150 to 200 tons per day. The Pluma plant also contains a number of vats which can be utilized, and the warehouse and machine-shop, which were not damaged by the fire, contain much valuable machinery, repair parts, supplies, and the usual layout of tools found in a small machine-shop. With all of these accessories at hand, the engineers of the Company estimate that the plant as outlined will cost \$46,000. It is also planned to expend \$8500 in mine development and equipment in order to make the mine workings convenient to the mill. The trustees for the bondholders have in hand \$73,280 of insurance collected on the fire of the old mill, and have agreed that the present expenditures may be made from this money. Ore supplies for the new plant will be drawn from the North lode, Carstreet, and Black Moon, which are stated to have 48,000 tons in sight at the present time, the Mark Twain, Sunnyside No. 1, Ben Hur, White Pine, Hardscrabble, and others. The new plant will use gyratory crushers, rolls, Chilean mills, Dorr classifiers, and the continuous decantation and counter-current system of slime treat-

Toward this work the county commissioners have appropriated \$250. The property consists of 185 acres, which includes a good territory of splendid timber, a good mill-site, and is traversed by Two Bit creek, which carries enough water to supply a large cyanide plant. Administration of the affairs will be left to a board of five trustees, of which the owners, John Treber and A. T. Roos, will be members. The club will select two members, and these four will select the fifth man. Should this venture prove successful, the club will take up other properties and handle them in a similar manner.

A steam hoist is being installed at the Titanic property, at Carbonate, which, with the air-compressor, will be run by steam from the Iron Hill plant, 150 ft. distant. The Titanic shaft is 100 ft. deep, and water has commenced to show in the shaft. It is proposed to dewater the Iron Hill shaft to the 300-ft. level, believing that this will drain the Titanic workings, and as soon as a skip is completed and coal delivered this will be commenced.

Lessees on the Ironsides property, in Squaw creek, are preparing for an all-winter siege in the snows of that locality, and about the most important work under way is the construction of ore-bins in which the ore excavated during the winter will be stored. This work will be completed before the snow comes, and in the meantime shipments will continue until the roads are impassable. Three cars of smelting ore, the poorest of which was worth \$30, has been shipped in the past month, and two cars of milling grade are now being loaded for shipment to the Golden Reward mill at Deadwood.

Wasp No. 2 paid its regular dividend of 1 cent per share on August 14. The mine is operating regularly at

full capacity, 500 tons per day, and a good surplus fund is being built up in addition to the distribution of profits. It is estimated that there is a supply of ore sufficient to operate at present capacity for six years now in sight in the quartzite deposits alone.

New Reliance is dropping 30 stamps and handling a satisfactory tonnage of good grade ore. The ore is quite hard, and is crushed fine, so that the daily capacity is a little under 100 tons. Diaphragm pumps have been installed lately to replace the air-lifts for moving pulp from tank to tank in the continuous-decantation process. Mr. Bowman, the manager, states that this change resulted in a fair saving of electric power. The pumps require less supervision than the air-lifts, and the management is well pleased with the change. The ore-supply is at present being drawn from workings near the top of the hill, and will come from there until cold weather sets in, when the scene of operations will be changed to the tunnel workings directly at the rear of the mill.

The Bismarck mill, at Flatiron, is operating successfully at full capacity, 300 tons per day, and is showing a profit on operations. The ore is mined by glory-hole and trammed to the mill, where, after coarse crushing, the entire product is leached with cyanide solutions. So economically has the work been laid out that during the past month total cost of mining and milling, including general expenses, was only 95c. per ton. This figure did not include many items of repairs, which will be higher as the mill gets older, but on the other hand, some economies may be effected which will offset them; for instance, a mechanical haulage system, eliminating horses, to handle the ore between mine and mill, would result in a saving. On the basis of present operations, the property is earning a good profit.

The Golden Gate property, at the head of Blacktail gulch, is being thoroughly sampled by W. T. Boley, who represents the Chicago owners. The old workings have been dewatered and carefully sampled. Mr. Boley is also making a thorough examination of a bed of quartzite which outcrops on the south end of the ground, believing that it will be possible to handle it satisfactorily on a large scale. The bed is nearly 20 ft. thick. Preparations are being made to take a sample of several hundred tons in order to get a reliable sample of the whole bed. This amount will be removed and shipped to some local plant where it can be crushed and quartered for assay and treatment. In addition to this deposit, there are a number of smaller shoots of ore of good value, and altogether it is quite probable that a mill will be built.

Exploratory work at the Elliptic, which is under bond to the Strattan Venture Corporation, headed by Frank S. Strattan, consists of reaming out the diamond-drill hole which is claimed to have produced high-grade cores in the past. The hole was drilled to a depth of nearly 800 ft. from the bottom of a 600-ft. shaft, and it was near the bottom of the hole that ore was found and good cores were produced. At the present time the reaming has been completed to a point a little more than 600 ft. below the collar of the hole, progress having been slower than was anticipated, but within the next two weeks it is expected that the bottom will be reached.

On August 15 the Homestake Mining Co. declared monthly dividend No. 416, constituting a record in the annals of gold mining. Starting its dividend disbursements in October 1878, they have been regular each month with the exception of two short periods, when from extraneous causes the mine was closed. With next month, September, the Company will have completed 35 years of dividend payments. It is interesting to note that the present dividend is one of the biggest ever declared, amounting to 65c. per share on 251,160 shares issued. It means the distribution of \$163,254 among the stockholders. And the end is not yet. The Homestake probably has more ore reserves than any other gold mine in the world. They approximate 30,000,000 tons, or enough to operate at present capacity for twenty years. And all of this at the shallow depth of 1900 ft., with a large ore-shoot still going down and producing from the lowest levels some of the richest ore ever found in the mine.

The First National Gold Mining Co. has been organized by Detroit people, taking over the Forest City property near Hill City, Pennington county. The officers are W. J. Blake, president and manager; John B. Shefflett, vice-president; Henry J. Guthard, secretary and treasurer, and George P. Good, consulting engineer. The property consists of 20 acres, on which a shaft 110 ft. and lateral workings disclose a shoot of high-grade free-milling ore. A contract has been let to sink the shaft an additional 200 ft., and work will probably start by the first of September. A 10-stamp mill was erected last fall, which is described as a neat plant of its kind. It is equipped with Pierce amalgamators and Wilfley tables. It is probable that a cyanide annex will be added.

The Black Hills Tungsten Co. is employing a number of men in both mining and milling construction. The property is near Hill City and is to be equipped with a small concentrating plant as quickly as the work can be completed.

TORONTO, CANADA

CROWN RESERVE MINE AND THE SHARE MARKET.—DEVELOPMENT AT THE BEAVER, YORK ONTARIO, AND LUMSDEN.—LA ROSE PRODUCTION.

The principal feature of mining interest this week has been the passing of the bonus on Crown Reserve stock, as announced by the directors on August 11. The Company, in addition to the regular monthly dividend of 2%, has been paying a bonus of 3% to stockholders. The latter has been discontinued, the reason assigned being the pinching out of the Carson vein, the leading producer in the mine. For some days previous to the announcement the stock of the Crown Reserve had been steadily falling on account of large blocks having been thrown on the market. The passing of the bonus was followed by a further slump, the stock dropping to \$1.70, the lowest price since 1908. Reports alleged that the directors, taking advantage of inside information, had sold stock heavily before the general public was made aware of the conditions, but all statements to that effect have been emphatically denied by Mr. Carson, the president, and his fellow-directors. Nevertheless, it is clear that some extensive stockholders must have had an inkling of how matters stood, and the affair has done much to weaken public confidence in mining ventures. The future of the Company now appears to be entirely dependent on the success of the project to drain Kerr lake in the hope of increasing the ore reserves. The Beaver, which is now cutting a station at the 800-ft. level, has attained the deepest point of any mine in the Cobalt area. Preparations are being made to cross-cut east for the main or No. 5 vein, which at 700 ft. shows a continuous ore-shoot, warranting exploration at the lower depth. Development work on the other levels has been satisfactory. A stringer from No. 5 has been picked up at 460 and 530 ft., showing 2 in. of 5000-oz. ore. The production of La Rose for July was 226,626 oz., the total revenue being \$136,815, and the profit \$81,413. The cash surplus at the end of the month was \$1,418,404, and the value of outstanding shipments and ore ready for shipment, \$299,411. At the York Ontario, formerly the King Edward, a rich ore-shoot, showing from one to three inches of high-grade ore, has been cut and found continuous for 20 ft. The Company is preparing to ship two cars of concentrate and high-grade ore. The Lumsden, situated near the Temiskaming and Beaver properties, now appears on the list of shippers, having sent out 20 tons of high-grade ore which had been accumulating for some time. Short shoots of rich ore have been found from time to time, mostly in the 250 and 300-ft. levels, in the Keewatin formation. Three drills are at work.

During July the Nipissing high and low-grade mills treated 177 and 7268 tons of ore, respectively, the product being worth \$314,115. Hydraulic prospecting and underground work was satisfactory.

On August 20 the Nipissing company shipped to England 212 bars of bullion valued at \$152,524, which is claimed to be a record shipment. The Buffalo company also sent out 141 bars worth \$82,837.

General Mining News

ALASKA

According to Alfred H. Brooks, in an advance chapter from 'Mineral Resources of the United States in 1912,' metalliferous mining in this territory made important advances during 1912. The production was as follows:

Gold, ounces	829,435	valued at	\$17,145,951
Silver, ounces	515,186	valued at	316,839
Copper, pounds	29,230,491	valued at	4,823,031

Total value\$22,285,821

FAIRBANKS

During the third week of July there was a good fall of rain in the district, and there is plenty of water available. In spite of the shortage of water on Goldstream, operations on No. 17 have not had to be suspended or curtailed, this being due to the fact that the owners of the property are also the owners of the Goldstream ditch, and this still provides a full sluice head. It is expected that a large crew will be kept steadily at work for the balance of the season, when in all likelihood the claim will have been exhausted. This property is worked under lease by Peterson, Craig & Johnson, who are taking out 11,000 ft. of bedrock weekly. The ground is low grade, but profitable. The dredge of the Alaska Exploration Co. is to be overhauled and work probably started on No. 7 and 8 above, Fairbanks creek. At the Newsboy mine there are fifteen men employed. The manager, Louis Golden, states that there is six months' ore-supply on the 150-ft. level, where the vein is from 8 to 12 ft. wide. On the 200-ft. level the vein was cut 225 ft. from the shaft. It is 18 in. wide, but of no value. On the east end of this level, 25 ft. from the shaft, the vein is 30 in. wide, worth from \$15 to \$20 per ton, while there is 42 inches in a raise of about the same value. The 5-stamp Joshua Hendy mill works one shift. The *Fairbanks Weekly Times* suggests that the new placer district in Alaska be called Shusana, instead of Shushanna, Chusana, and Chisana, the first being the nearest to the Indian pronunciation. The trail, says W. H. Newton, a well known trader, is dry and well defined as far as Tanana crossing. Beyond Tetlin, he says, it would be prudent to hire Indian guides. From Tanana crossing to the Chisana, and far up the Chisana, the water is so 'slack' that the wind will blow a boat upstream. The total distance from Fairbanks is 335 miles, taking about 12 to 13 days.

JUNEAU

The following are the July returns of the mines on Douglas island:

	Alaska Mexican.	Alaska Treadwell.	Alaska United.
Stamps working	120	540	240
Ore crushed, tons	17,493	77,973	36,680
Concentrate saved, tons	394	1,449
Gold by amalgamation	\$18,573	\$101,984	\$49,324
Gold by cyanidation	18,867	92,394	43,063
Realizable value	37,066	192,435	91,464
Operating expenses	22,171	90,510	52,808
Construction	4,971	14,760	4,972
Net profit	9,923	87,164	33,684
Development, feet	80	474
Broken ore decrease, tons	4,846	2,808

On August 28 the Alaska Mexican, Alaska Treadwell, and Alaska United companies paid dividends of 30c., \$1, and 50c. per share, respectively.

Another group of coal claims in the Bering River field, the Chezum, has been rejected by the Land Office at Juneau. The decision is similar to the Cunningham case, and is based upon the point that the claimants failed to show that they had opened a mine on the ground. All charges of fraud were, however, dismissed.

NOME

The most important gold find in the vicinity of Nome since the discovery of the third beach-line was made on Golden Cow claim, as reported by telegraph. Twenty dump-

car loads produced \$150 worth of gold. Rich placers have been found on Manila creek.

ARIZONA

COCHISE COUNTY

It is reported that the United States Circuit Court of Appeals at San Francisco has handed down its decision in the case of Synnott and others v. Tombstone Consolidated Mines Co., Ltd., and others, which judgment affirms a decision previously made by Judge Sloan of the United States District Court at Phoenix, which latter decision in turn affirmed the ruling of the referee in bankruptcy, Daniel McFarland, at Tombstone. The referee, in his decision, held that the holders of the bonds of the Tombstone company, being a total issue of \$3,000,000, were not entitled to prove their claim in bankruptcy. When the bondholders attempted to prove their bonds, they were objected to by the general creditors and by A. L. Grow, trustee in bankruptcy. The unsecured claims which have been proved and allowed amount to upward of \$2,500,000. While the text of the decision of the Circuit Court of Appeals has not been received, it will probably have the effect of terminating the pending litigation between the bondholders and the general creditors. Disposal of this litigation will doubtless bring about the resumption of operations in the mines of the Company at Tombstone.

According to Charles E. Knox, president of the Montana-Tonopah Mining Co., Nevada, the Commonwealth mine, owned by that Company, is proving to be a much larger property than was anticipated when it was purchased. On one level a stope 90 ft. wide is being opened, and the ore for a width of 18 ft. will average from \$11 to \$15 per ton, and the remainder profitable milling ore. On other levels large bodies are being opened, and there is fully 100% more ore in sight than when the mine was purchased. The new mill will be ready early in September.

GILA COUNTY

(Special Correspondence.)—The test of the electric smelting of copper ores at Globe resulted in an extraction of 98% of the copper content. The salient feature of the test was the fact that about 3500 kw. per ton charge was required for smelting. From this may be estimated the economical practicability of the furnace. The added features of absence of water-jackets and lightness of parts make the furnace peculiarly adaptable to carbonate deposits in high and inaccessible places, provided electric current can be supplied at a rate sufficiently low to make operation of the furnace an economical success.

Sultan & Wayne are reported to have abandoned their lease on the Gibson, where recently they were reported to have made successful tests of jigging the sulphide ores. It is also reported that the owners of the Gibson are negotiating with the Minerals Separation Co. for installation of a small flotation plant at the property, the chalcopyrite ores of the Gibson being favorable for that manner of recovery. The Iron Cap is mining more high-grade ore above the point in the east 650-ft. level drift where the vein widened so suddenly. The stope there is known as No. 3 and is being driven west to connect with No. 2 stope and driven east along the vein. The whole face of the main east drift on the 650-ft. level is in copper ore varying in daily average from 10 to 15% copper. The point where the vein widened on the 650-ft. level is about 494 ft. east from the shaft, and the face of the 800-ft. drift east is now about 210 ft. in the same direction, leaving about 285 ft. to be traversed before the shoot is found on the lower level, if the enlarged portion of the vein proves nearly vertical.

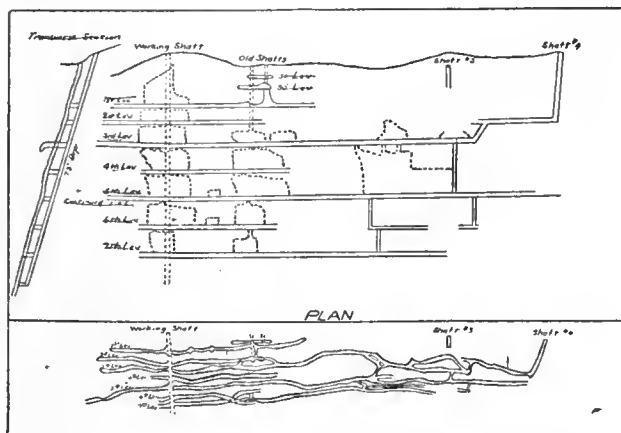

Miami, August 20.

It is reported that a successful attempt was made to smelt ore in an electric furnace at Globe on August 14. The test was made there at the instance of H. S. Paul, of Pittsburgh, who purchased the furnace from the Pittsburgh company, and had it shipped to Globe and set up on the ground of the Globe Light & Power Co., which supplied the current used for the trial run, Mr. Paul defraying the entire cost. The test was made on ore from the Copper Reef mine, 13 miles south of San Carlos. The ore contained 68% silica and 5.44% copper. The furnace is known as the

electric-resistance type, and has a capacity of 15 tons of ore per 24 hours. The furnace has a steel shell and an 18-in. lining of Grecian magnesite brick. A stationary electrode passes through the base of the furnace, about half an inch above the bottom of the brick lining, and a second electrode $4\frac{1}{2}$ ft. long and 4 in. diam. is suspended in the furnace and is raised and lowered by means of a wire cable attached to a small winch. The slag was thin and contained only a trace of copper. The copper produced was of higher grade than that from a blast-furnace, and there were no dust losses.

MOHAVE COUNTY

The Midnight mine has shipped a carload of concentrate to the Copper Queen smelter. The Copper Giant shaft is down 275 ft., and 5 ft. of \$35 ore is being opened. The Gold Road yielded \$18,000 from a six days' run of the mill,

TOM REED MINE WORKINGS.

while the Tom Reed produced \$88,000 in July. Outside mining properties are being purchased and developed by the Company, so that other sources of ore-supply will be available should anything occur to cut off the reserves of the main property. Some of the new mines are said to be developing satisfactorily.

PIMA COUNTY

(Special Correspondence.)—The Calumet & Arizona Copper Co. will make a preliminary survey for a railroad to be constructed from Tucson to its properties at Ajo, 80 miles southwest.

Tucson, August 21.

PINAL COUNTY

(Special Correspondence.)—In the Pioneer district, popularly known as the Superior district, the general tone is constantly improving. The Magma continues its shipments of high-grade ore *via* Florence to El Paso, and it is known that its drilling operations have revealed considerable high-grade copper ore at a depth of several hundred feet below the lowest present workings. It is still uncertain when the power-transmission line from the Roosevelt dam *via* Miami will be completed to Superior, but probably it will be early in 1914. The Calumet & Arizona, Reymert, and Ajax properties are being actively developed. At the point in the Ajax where the workings left the vein it had 15 ft. of ore assaying well in lead, zinc, copper, and some silver and gold. Indications are favorable for development of copper at the property, as both chalcocite and chalcopyrite are showing in the vein.

Florence, August 20.

(Special Correspondence.)—Certain mining districts in this county are being examined by C. E. Knox and E. A. Cowan of the Montana-Tonopah, Nevada, and Commonwealth, Arizona, companies, respectively.

Florence, August 21.

YUMA COUNTY

(Special Correspondence.)—Two tons of \$80 lead-silver ore has been shipped to the Selby smelter by George Norton. This came from the Eureka district, about 60 miles up the Colorado river, and was brought down by boat.

Yuma, August 21.

CALIFORNIA

Statistics of the oil-producing counties are as follows:

	Barrels.
Stocks, June 30	46,382,663
Production in July	8,573,906
	<hr/> 54,963,575
Consumption in July	8,325,402

Stocks, July 31 46,638,173

There were 48 rigs completed during the month, 337 wells drilling, 67 completed, 5 abandoned, and 6035 producing. Dividends amounted to \$734,771.

AMADOR COUNTY

The Kennedy Extension Gold Mining Co. is being sued for \$30,000 by John A. Gubson for injuries received while working in the Company's shaft.

MARIPOSA COUNTY

A 5-stamp mill, of 1000 lb. stamps, has been shipped to the Studhorse Flat mine, at Bagby, by John T. Carroll.

NEVADA COUNTY

A good deal of interest is being taken by Grass Valley people in a promising vein opened in a garage in the town.

SAN DIEGO COUNTY

About \$100,000 has been spent in developing the Montezuma gold mine, situated 11 miles from Warner's Hot Springs, by Pasadena men, headed by E. W. Knowlton, of Crown City. The company owns 18 claims in the San Ysidro range, and 15 gold-bearing veins have been opened. Present operations are confined to the Morning Star and Eureka claims, where the vein has been developed to 200 ft. depth, exposing good ore. From 12 to 18 men are employed, and further development is planned on the 250-ft. level when it is reached.

SISKIYOU COUNTY

(Special Correspondence.)—The Keables Mining Co. is working the Pine Grove placers, near Walker, with a drag-line excavator. The Company has completed an extensive line of flumes and the gravel scooped out by the excavator is discharged into the sluices and washed as in ordinary practice. It is said that prospects are good. San Francisco people are interested. Most of the placer mines in the Walker and Oak Bar districts have stopped work for the season, owing to scarcity of water. Drifts from No. 2 adit of the Cub Bear mine have entered the orebody, which yielded good grade quartz in the upper level. The shoot is small, and only the specimen grade quartz is being shipped. The Cub Bear is situated 16 miles from Etna and is operated by the Siskiyou Syndicate. A force of 12 men is employed on development work at the Dakin copper mine, near Fort Jones. Three shifts are worked. It is rumored that Eastern people are considering the acquisition of the property, Oakland people being the owners. Work will be resumed at the Bunker Hill placer group next winter. A new pipe-line has been decided on, together with substantial repairs to the flumes.

Fort Jones, August 18.

TUOLUMNE COUNTY

(Special Correspondence.)—An option has been secured by J. N. Lyon and others on several hundred acres of land situated a short distance southwest of Jamestown, through which, it is believed, the rich gravel channel uncovered in Table mountain extends. It is announced that active work will begin soon to develop the property. A number of men are engaged in general repair work at the Jumper, and it is understood that the early resumption of mining operations is assured. The long adit at the Paymaster mine, southeast of Tuolumne, is still being driven, and it is said that the operators are pleased with the present outlook. Work has begun on the Carlin property, near Jamestown, recently bonded to Howard Pollion, of New York. A hoist has been purchased, and when installed the working force will be increased.

Sonora, August 15.

Charles H. Segerstrom reports that the water is being rapidly lowered in the Dutch mine, and since June 1 it

has been reduced from the 800 to the 1400-ft. level. About the end of September the shaft and mine will be drained to 1700 ft. depth. Present operations in the mine are mostly confined to driving and stoping on the 300 and 800-ft. levels, and to reopening and prospecting on the 1000-ft. level. It is stated that C. E. and G. E. C. Boyd are negotiating a sale for the Rawhide and App mines, and it is generally believed that a strong syndicate has been formed for the purpose of not only acquiring these mines, but adjacent promising properties.

TRINITY COUNTY

The Alta Bert Gold Dredging Co. owns over 600 acres of ground along the Trinity river, near Trinity Center,

ALTA BERT DREDGE, NEAR TRINITY CENTER.

and the dredge, with 7½-cu. ft. buckets, has been in operation for about 19 months. A steel spud, weighing about 20 tons, has recently been added to the equipment.

COLORADO

The state mining commissioner, Thomas R. Henahan, has issued a circular containing figures on the mining industry of this state. He states that the mines of Colorado supplied 85½% of all the tonnage originating in this state on the Denver & Rio Grande, Colorado & Southern, Colorado Midland, and Denver & Salt Lake railroads in 1912, leaving only 14½% to be supplied in 1912 by agriculture, manufacturing, and all other industries not associated with mining. In Denver there are about 80,000 people dependent on mining for a living, while in the whole state there are 382,500 people dependent on the industry.

OURAY COUNTY

The annual report of the Mountain Top Mining Co. contains the following information: The exploration work from the adit before cutting the vein where it was of normal width amounted to 108 ft., and the drift north on the vein to 168 ft., making a total length of new workings on July 31 of 2501 ft., of which 2250 ft. was driven since January 1. In the north drift the vein has varied from 2½ to 8 ft. in width, and the main streak from 6 to 22 in., the latter averaging a little over 10 in. for the entire distance and being 18 in. at the present face. The average of 22 samples from the streak was \$7.86 gold and 64.4 oz. silver, or a total value of about \$46.50, per ton. The flow of water from the adit is 140 gal. per minute. A good millsite has been secured about 5000 ft. from the portal of the adit, and 1000 ft. from the Atlas mill, and is safe from snowslides. The ground between the adit and site is suitable for an aerial tramway.

TELLER COUNTY (CRIPPLE CREEK)

During July, eight of the local mills, the Portland, Stratton's Independence, Colburn-Ajax, Kavanagh-Jo Dandy, Gaylord-Dante, Rex Mining & Milling Co., Wild Horse, and Isabella plants, treated 35,373 tons of ore with a gross value of \$85,428. This low-grade ore ranged in value from \$1.10 to \$2.84 per ton, with a general average value of \$2.41 per ton. This tonnage will be increased soon by the addition to the Portland mill and the completion of the Neville

and El Oro mills. The Gaylord mill is treating about 75 tons per day, and a clean-up on August 20 resulted in bullion worth \$4000.

Two distinct ore-shoots have been opened on the 1600-ft. level of the Portland, and they are producing good ore. No. 2 shaft is dry, and No. 1 is down 1100 ft. at present, and it will be necessary to sink 562 ft. to have the bottom levels of both shafts on the same plane. At 300 ft. in the Gold Bond property, a rich shoot has been opened. The Elkton company has paid a 2c. dividend, amounting to \$50,000. The new ore-shoot opened by lessees in the Dexter mine on Bull hill has been opened 50 ft. It averages 3 ft. in width and about \$40 per ton, the yield being two cars per week.

NEVADA

CLARK COUNTY

The Yellow Pine mining district, sometimes called the Good Springs district, in the southwestern part of this county, is well described by James M. Hill in Bulletin 540-F. of the U. S. Geological Survey. From 1902 to 1911, inclusive, the production was: gold, \$196,515; silver, 101,779 fine ounces; copper, 521,411 lb.; lead, 5,138,247 lb.; and zinc, 15,834,643 lb., with a total value of \$1,453,715. The Yellow Pine district has a varied production. Exclusively gold ores are obtained from at least four different mines. There is also some opportunity for the development of prospects which may yield various oxidized copper ores that are said to carry a little gold. By far the most important mines at present are those from which oxidized zinc and lead ores are obtained. These produce three classes of ore, namely, lead ore, zinc ore, and zinc-lead ore, each one of which requires different treatment. All three classes may be taken from a single mine, or they may be found in distinct deposits. Three mills have been built, one for gold ores and two for zinc-lead ores. The Keystone had two 4-ft. Huntington mills. The Yellow Pine mill concentrates an ore averaging 16 to 17.5% lead, 27.8 to 29.8% zinc, and 11 oz. silver.

HUMBOLDT COUNTY

The Causten adit on Nenzel hill, the longest that has been driven at Rochester, cut the vein on August 21 at a depth of 430 ft. The development is the most important recorded in the history of this place, for it demonstrates the much mooted question of the depth of the ore. Another important development was the cutting of 5 ft. of \$75 ore in the Stoker adit on the Rochester Weaver property. The development was made at a depth of 125 feet.

NYE COUNTY

Heavy thunderstorms, on August 24, caused considerable damage at Tonopah, Manhattan, and Goldfield, while the transmission lines of the Nevada-California Power Co. were badly damaged, and the sub-station at Palmetto partly destroyed by fire. All power was shut off from many mining districts in Nevada for some time.

During July, 10 mines at Tonopah produced 48,227 tons of ore, yielding 813,385 oz. bullion and 183 tons of concentrate, the gross value of the ore being \$961,440. The yield during the week ended August 23 was 12,318 tons, valued at \$283,970.

STOREY COUNTY

Bullion tax statements for the second quarter of the year contain the following data:

	Tons.	Yield.	Profit.
Ophir, ore	1363	\$37,134	\$ 3,484
Ophir, tailing	7640	34,108	22,152
Comstock-Phoenix	1142	21,864	*613
Crown Point	5735	34,064	*486
Yellow Jacket	2536
Belcher	1046	3,697	*7,598
Hale & Norcross lessees.....	322	3,039	*302

*Loss.

Arrangements have been concluded with the Starrett Pump Co. whereby two of its pumps will be utilized in lowering the water at the north end from the 2500 to the 2700-ft. level at the C. & C. shaft. These pumps will be of 1000-gal. capacity each per minute, and will be low-

ered through the old Consolidated Virginia winze easterly of the C. & C. shaft station at the 2500-ft. level. This winze is in first-class condition, as far as it is possible to determine, and gives assurance that there will be no delay in reaching the 2700-ft. level.

WHITE PINE COUNTY

The following are details of the new roaster stack which the Nevada Consolidated company is erecting at the Step-toe plant. The new stack is being erected on the south side of the dust-chamber and about 150 ft. west of the site of the old one. It will be 275 ft. high and is 19 ft. diam. outside. It rests on a concrete foundation 35 ft. diam. set deep in the ground. The lower section of the stack is hexagonal in shape and for 100 ft. it will be constructed of ordinary pressed brick of the best quality, and above 100 ft. the construction will be of stack tile. The stack is now about 80 ft. high and progress will be made at the rate of five feet per day.

On August 19 the first Giroux ore to be mined by steam-shovels went down Robinson cañon in a train of 21 cars. The ore was from the Ora claim and was mined by one of the Nevada Consolidated shovels from the Liberty pit for the purpose of removing the right-of-way to the pit to facilitate Nevada Consolidated operations. More of the ore is being loaded and as the regular production from the Giroux is being made as usual, the output for the week will be materially increased over the average of 1000 tons per day. During July the Nevada Consolidated Copper Co. produced 5,403,919 lb. of copper.

UTAH

JUAB COUNTY

High temperatures from 90 to 100°F. on the 1000-ft. level of the Tintic Standard have interfered with development, so the Company is changing the 9-in. air-pipe from the shaft to the face of the drift, a distance of about 1200 ft., to a 16-in. line. This is expected to remedy the trouble. A No. 4 rotary blower is sending air down the present pipe. A large low-grade orebody has been opened on the 1000-ft. level of the Victoria. It is probable that the Lower Mammoth will resume shipping zinc ore in September. The new cyanide plant of Griggs, Carter, and Castleton yielded about \$1500 from 960 tons of tailing treated. Results are said to confirm the experiments.

SALT LAKE COUNTY

It is stated that the Yampa smelter has been offered for sale, which effectually settles the question frequently asked in regard to the Yampa Smelting Co.'s intention of resuming smelting operations. The Yampa smelter is at Bingham Canyon. It was constructed in 1904, and enlarged in 1906 to a daily capacity of 1000 tons. The plant for several years was in operation on the low-grade copper ore of the property in Bingham, but upon the negotiation of a smelting contract with the American Smelting & Refining Co. the plant was closed, and it has remained idle to date. At one time the Yampa was one of the largest copper ore producers of the West, but the more recent policy of the Company has been to cease wholesale mining so that a smaller but much more valuable tonnage might be secured at a profit.

SUMMIT COUNTY

Ore shipments from Park City during the past week totaled 1628 tons. The Silver King Consolidated has declared a dividend of 25c. per share, amounting to \$155,000.

WASHINGTON

OKANOGAN COUNTY

(Special Correspondence.)—Crescent Mining Co., Ltd., has installed a Samson turbine electric plant and sawmill, the latter being for the Company's own use. Temple-Ingersoll 5-C drills will be used to drive a 1600-ft. adit to cross-cut the main vein at the 1300-ft. level. Lumber is being cut for the large compressor and hydro-electric plant which is to be installed next spring, the present plant being a temporary one. The ore consists of chalcopryrite, bornite, pyrite, and quartz.

Twisp, August 23.

SPOKANE COUNTY

The *Spokesman-Review* published the following table showing the dividends paid by mining companies operating in the Coeur d'Alene district, Idaho, Ferry and Stevens counties, Washington, and the Boundary district, British Columbia, during the first half of the current year.

	1912.	1913.
British Columbia Copper	\$ 177,512	\$ 88,756
Bunker Hill	752,100	523,200
Federal	720,000	360,000
Granby	1,600,000	450,000
Hecla	300,000	220,000
Hedley	360,000	120,000
*Hercules	600,000	280,000
International Coal & Coke Co.	60,000
Knob Hill	5,000	15,000
Le Roi	60,000	43,200
Republic Mines Corporation	85,000
Snowstorm	75,000	89,979
Standard	425,000	400,000
Stewart	123,836
Success	180,000	90,000
United Copper	50,000
Total	\$5,389,612	\$2,863,971
*Estimated.		

CHILE

The report of the Braden Copper Co. for July, stating that the No. 1 Teniente adit had advanced in that period 68 ft. in ore averaging 4.73% copper, indicates that this working has probably again reached the contact. The No. 1 Teniente adit is the most important development in the Braden mine. It has already advanced several thousand feet in ore. The face of the adit is 1400 ft. below the surface and is being driven into virgin ground with no work done either above to the surface or below the adit. Ahead of the adit there are no workings for a distance of 1000 ft. until the Fortuna adit is reached, where ore of a good grade has also been opened.

COSTA RICA

The Abangarez Gold Fields Co. reports as follows for June:

	June.	Half-year.
Ore crushed, tons	6,170	29,186
Tailing leached, tons	689	2,777
Slime treated, tons	4,902	24,112
By amalgamation	\$13,655	\$ 65,700
By cyanidation	42,516	185,810
Total	\$56,171	\$251,510
Cost of operation, marketing, and administration (exclusive of betterments)	47,942	290,212
Profit	\$ 8,229	*\$ 38,702
Betterment expenditure	\$5,174	\$47,156
*Deficit.		

MEXICO

BAJA CALIFORNIA

The Boleo Copper Co. produced 14,619,920 lb. of copper during the first half of the current year. This is about 1,000,000 lb. more than the corresponding period of last year.

HIDALGO

The report of the Santa Gertrudis company shows the following regarding the ore reserves:

Ore opened and partly developed, tons.....	778,000
Profit in ore	\$3,740,000
Probable ore, tons	269,000
Profit	\$1,040,000

The San Rafael y Anexas Mining Co., one of the big concerns of the Pachuca district, has arranged to operate the San Pedro Analco mines in the Hostotipaquillo district of Jalisco on a bond and lease. The San Rafael company is under the management of Edmund Girault. It

owns mines in the Parral district of Chihuahua as well as in the Pachuca district.

JALISCO

A new body of rich ore has been opened in the Mololoa mines in the Hostotipaquillo district of this state, the property of the Mololoa Mining Co., a Makeever enterprise. Much of the ore taken out so far runs 57 kg. silver per ton, and averages 2.5 gm. gold per kilogram of silver. The new body of rich ore is between the old Mololoa mine and the Soledad mine of the Mololoa group, and was opened by a drift on No. 6 level of the Soledad. The addition to the El Favor mill in the Hostotipaquillo district, which is to be used exclusively for the treatment of Mololoa

EL FAVOR MILL.

ores, will be ready for operation within a month. The addition consists of 15 stamps, two tube-mills, concentrators, and cyanide plant, and its operation will permit of the treatment of a greatly increased tonnage of El Favor ores in the original El Favor 20-stamp mill.

MEXICO

The El Oro Mining & Railway Co., Ltd., reports for July: Mill ran 30 days and treated 23,250 tons of ore and 14,080 tons of tailing, yielding bullion valued at \$169,880; working expenses and expenditures on development, 123,050; profit, \$46,830; railway profit, \$13,970; total profit, \$60,800.

SONORA

(Special Correspondence.)—The Nacozari Consolidated Copper Co. is arranging to build a concentrator at its property, near Nacozari, by the first of the coming year, and for this purpose the board of directors has authorized the sale of 25,000 shares at \$1 per share. The Company did 600 ft. of work during the past year, and the total development done at the property is 1900 ft., 1500 ft. of which is in adits. A recent report states that the vein cut in the main adit has widened out to over 6 ft. Assays from samples taken across the face of the drift gave the following: 80c. gold, 155 oz. silver, 12% copper, 17% lead, and 2% zinc. The president of the Company is John G. Alexander.

The Calumet & Sonora of Cananea shipped 721 tons of concentrate to the smelter during July. There was 347 tons of lead concentrate, 298 tons of zinc, and 75 tons of copper concentrate in the lot. During the past week the main drift shafting at the wet mill broke, resulting in the mill being shut down for two days.

Cananea, August 23.

The Tigre Mining Co., operating at El Tigre, reports as follows for July:

Ore crushed, tons	5,119
Tailing (current and dump) treated, tons	6,635
Value of shipping ore	\$ 12,955
Value of concentrate	42,142
Value of cyanide bullion.....	64,268

Total	\$119,365
All expenditure, including taxes	76,970

Net profit\$ 42,395

Owing to interruptions to electric power, due to thunderstorms, the mill was shut down for five days.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

P. R. WHITMAN is at Los Angeles.

C. F. RAND was at Ely this week.

L. S. AUSTIN has returned to Salt Lake City.

C. S. HERZIG was in San Francisco last week.

HENNEN JENNINGS was in San Francisco Friday.

ADOLPH KNOPF was in San Francisco this week.

P. D. BURTT has left Cordova for the Chisana gold find.

S. H. BROCKUNIER, of Nevada City, has gone to Phoenix.

G. B. STREET has gone to Valdez and other Alaskan points.

JOSEPH DURKEE has returned to Berkeley from Reno, Nevada.

L. Y. YOUNG will be lecturer at the University of Illinois this year.

V. C. BENNETT, formerly of Mexico, is now at Sydney, Australia.

BERTRAM HUNT has returned from Broomassie, West Africa, to London.

THOMAS T. READ has returned to New York from Sudbury and Toronto.

GEORGE H. YOUNG has accepted a professorship in the School of Mines of Minnesota.

VAN H. MANNINO and GEORGE S. RICE, of the U. S. Bureau of Mines, are in San Francisco.

R. B. LAMB, of Toronto, is in Nevada on professional work, until the end of September.

CHARLES JANIN has returned to southern France from a visit to Switzerland and Germany.

J. A. HOLMES is in the Nenana coalfields, but will leave Valdez September 12 for the Matanuska.

GEORGE L. ALEXANDER, manager of American Type Founders Co., San Francisco, died on August 19.

REIJI KANDA, who has been on sick leave at Lake Hamana, Japan, has recovered and is back at Tokyo.

J. P. HUTCHINS has been examining platinum mines in the Urals, and is now in the Lena region, Siberia.

JOSEPH H. PLAYTER has returned to Golconda, Nevada, from Salt Lake City and an examination trip in Utah and Colorado.

H. C. RAY has left Butte, Montana, and is now at the School of Mines, University of Pittsburgh, Pittsburgh, Pennsylvania.

D. W. BRUNTON and JOHN W. FINCH have been appointed consulting engineers for the city of Denver in connection with the proposed Moffat tunnel.

L. D. RICKETTS and J. C. GREENWAY will sail from New York the middle of September for Europe. Among other countries they expect to visit the Balkan states.

TADASHIRO INOUE has been transferred from the Imperial University at Kyoto to the corresponding institution at Tokyo. He will be succeeded at Kyoto by K. INE, who has been studying in Germany and is now visiting the United States.

Company Reports

DALY-JUDGE MINING COMPANY

This Company operates at Park City, Utah, and the report of the general manager, George W. Lambourne, covers the first half of 1913. Results may be shown as follows:

Development, feet	9,000
Average monthly cost of development.....	\$16,280
Concentrating ore, tons	25,514
Shipping ore, tons	2,155
Lead concentrate, tons	5,808
Zinc concentrate, tons	2,489
Average monthly earnings	\$15,485
Balance July 1, 1913	\$527,386

Most of the development was done on the 500 to 2300-ft. levels. In regard to the development done, the greater portion was toward the Bonanza Flat section in following the fissure systems, and the faces of the various drifts were kept far ahead of the workings. This was necessary, as drainage was thereby afforded, so that more detailed exploratory work was possible. There is therefore in the great number of points of attack a marked advantage for the future work, and good results are to be expected with the least loss of time and money.

To date the Daly-Judge company has proved the famous Daly vein for a distance of over 4000 ft. southwest of the shaft, and with a large territory still awaiting development, throughout which this vein trends. In addition to its extensive development campaign at the mine, the Daly-Judge company has a large interest in the Snake Creek Tunnel Co., which is another Park City enterprise now driving a tunnel at the rate of 300 to 400 ft. per month.

MINES COMPANY OF AMERICA

This Company operates four important properties in northern Mexico, and the report covers the quarter ended March 31, 1913.

Bullion and concentrate production.....	\$535,679
Sundry receipts	6,566

Total	\$542,245
Mining, milling, etc.....	388,638

Operating profit	\$153,607
Net profit after interest, general expenses, and taxes	152,052

According to the last advices received, all of the Mines Company's properties were still operating, though at two of the mines railway communication had been somewhat irregular.

Recent development work has been meeting with good results. At the Dolores, on the Prieta adit-level, an orebody has been cut, assays of which have returned \$12.44, \$25.25, and \$34.68 per ton. The average width of this ore is 2 to 4 ft. In a cross-cut which is being driven to the west at the mouth of the main adit, a body of sulphide ore has been cut which assays about \$100 per ton. The average width of this ore is 2 feet.

At the El Rayo mine an adit is being driven north and south from the shaft. It is expected that this will have soon gained a point underneath the large orebodies in the old El Rayo mine, and in this section some important developments are expected.

At the Creston-Colorado property, in the Colorado mine, between the No. 3 and 4 levels, an orebody from 4 to 6 ft. wide, assaying \$6 per ton, is being opened. At the Creston mine, on No. 6 level, a large amount of development is being done. This has resulted in opening a shoot averaging 8 ft. wide and assaying \$6 to \$8 per ton.

At the La Dura property, in the Prieta mine, on the 1040-ft. level, in an incline known as No. 3, some promising developments have resulted, and ore averaging from 160 to 200 oz. per ton silver has been opened. At the Gloria mine some good ore has been opened in the northern portion of the property on the No. 5, 7, 8, and 9 levels. This ore,

although somewhat lower than that at the Prieta, is of a good grade.

NORTH BROKEN HILL MINING COMPANY.

This Company was registered at Melbourne in 1905, in reconstruction of a former colonial company of the same name, registered in 1895. The property owned is situated at Broken Hill, New South Wales, and yields silver, lead, and zinc. The latest report of the Company covers the period ended November 30, 1912. On December 4, 1912, the North Broken Hill, Ltd., was registered to acquire the undertaking of the North Broken Hill Mining Co., no liability. The authorized capital of the latter Company is \$960,000, in 200,000 shares of \$4.80 each; all the shares are issued and fully paid. The total number of shares of the North Broken Hill, Ltd., is 600,000, and all of them were allotted as fully paid otherwise than in cash as part of the consideration for the purchase by the Company of the undertaking and assets of the North Broken Hill Mining Co., no liability. On the report of this last-named Company the amount of ore extracted is given as 125,944 tons. During the period the mill treated 125,738 tons of ore assaying 15.81% lead, 7.18 oz. silver, and 13.35% zinc, yielding 21,781 tons of concentrate assaying 69.03% lead, 22.19 oz. silver, and 6.89% zinc. The recovery of metals was: lead 75.62%, silver 53.52%, zinc 8.95%. The total working cost was \$24.62 per ton of lead concentrate. The total output of zinc tailing was delivered to the Amalgamated Zinc Co. Two dividends were declared, a total of \$3.84 per share, amounting to \$768,000. An additional dividend of \$1.08 and bonus of 36c. per share has been declared payable on March 26, 1913, equal to 24c. per share in the shares in the 'Limited' company. The balance of liquid assets over liabilities is \$1,507,000. There was a great shortage of labor, and the contract miners earned a high rate of wages.

ST. JOHN DEL REY MINING COMPANY, LTD.

This Company was first established in 1830, and was reconstructed in 1858, 1887, and again in 1888. It owns the Morro Velho and Cuiaba gold mines in Brazil. The output from the Morro Velho mine during 1912 was 21,550 tons less than that of the preceding year. The average amount recovered from the ore, \$11.04 per ton, was about the same, but the total produce shows a reduction of \$220,000. The falling-off was entirely due to the inadequate labor available. Although the working cost, \$1,214,000, is lower than that of last year by \$67,200, the average of \$7.06 per ton of mineral treated is higher, owing to the reduced tonnage. The profit, \$566,000, although less than that of last year, \$676,800, compares favorably with the average profit of the past five years, namely \$518,000. The Brazilian authorities have granted the Company permission to introduce Japanese laborers and the Japanese Foreign Office has approved a contract made with the Emigration Society of Tokyo, including a contract with the individual laborers, who can engage for 5 years of service with the option of returning to Japan after 2½ years of service, if they so desire. A trial will be made with about 100 men, who are expected to reach the mine in September. Hard ore for the tube-mills was obtained during the year from the Cuiaba and Rapasos properties, but no mining work of importance was done there. In addition to the working cost \$1,214,000 the sum of \$83,000 was paid on duty and transport charges, \$20,000 on development, \$25,000 on the London office, \$20,000 as debenture interest, and \$24,000 as income tax. The preference shares received \$48,000, the usual 10%, and the ordinary shares received a similar dividend absorbing \$264,000. The remainder, \$249,000 was transferred to capital account for expenditures on new plant, etc. Recently, extensive deposits of iron ore have been discovered on the Company's property and a great deal of adjoining territory has also been acquired by purchase. It is estimated that 160,000,000 tons of ore is available, the average assay from 570 samples taken underground showing 67.3% iron and 0.053% phosphorus. The iron is neither as hard as the Lake Superior hard ores, nor as soft as the soft ores, and it is expected that it can be easily stoped and will yield an excellent smelting product.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

REGULAR TESTS should be made of the burning rate of fuse used in mines, and results posted in a conspicuous place.

PAVING BRICK is being made at Middlesborough, England, from blast-furnace slag. The bricks weigh 14 lb. each and wear well.

TIMBERS in manways in daily use in mines should be cleared of all loose rock lodged upon them at least once in every 24 hours. Manways should also be kept clear of all obstructions.

SAND-FILLING OF STOPES at the Robinson Deep mine, Johannesburg, is done by carrying the sand to the mine by gravity, and then sending it underground through a bore-hole 1700 ft. deep.

ICELAND, an island northeast of the British Isles, and just south of the Arctic Circle, has large water-power possibilities, and a Norwegian concern, the Nitrogen Products Co., has an option on 410,000 hp. in that country.

CYANAMIDE, nitric acid, ammonium nitrite, fertilizers, and other nitrogenous products are to be manufactured at Aura, near Kristiansund, in Norway, when the new 100,000-hp. hydro-electric power-plant is erected.

ELECTRIC POWER is to be generated by two hydro-electric stations in New Caledonia, and will be used in the manufacture of nickel and chrome alloys, this island being rich in these ores. The proposed scheme will cost about \$1,000,000 to \$1,170,000, and will take three years to finish.

A NITRE DEPOSIT occurs along the face of cliffs of black limestone, about $3\frac{1}{2}$ miles northeast of Meirose, Silverbow county, Montana, the salt consisting of a snowy white to slightly yellowish mass of needle-like crystals, according to R. W. Richards. Analyses show the following: calcium sulphate, 13.94%; sodium sulphate, 3.30%; sodium chloride, 20.42%; sodium nitrate, 21.77%; nitre, 39.48%, and nitrogen pentoxide, 1.19%. The value of the deposits cannot be safely estimated from the data collected, and it is calculated that a gross yield of about \$1.80 per ton of rock treated would result.

EXPERIMENTS on a silver ore containing a large percentage of manganese were made at the Thames School of Mines, New Zealand, several years ago, with the following results. The ore was worth 2.5 dwt. per ton in gold and 2.8 oz. in silver. Part of the sample, which weighed 3000 lb., was dry crushed and leached by 0.5% cyanide solution in a vat, by which method there was a saving of gold 95% and silver 63.3%. The remainder of the sample was treated by hot pau amalgamation (Washoe process), which resulted in an extraction of gold 94% and silver 14%. During crushing, the ore, which consisted of soft, friable, somewhat clayey quartz with the large percentage of manganese mentioned, formed a large percentage of slime which was troublesome in cyaniding by percolation.

VELOCITY CARDS of the stamps at the Winona mill, Lake Superior, show a blow from 24 to 33-ft. tons. The total cost of regrinding copper-bearing rock at this plant averages 26.93c. per ton reground. The 8-ft. diam. by 30-in. straight-face Hardinge mills have proved to be the most economical in power cost per ton ground, and also has the largest capacity of any tried. They are fitted with Falk's cut herringbone gears, according to R. B. Seeber, in a paper prepared for the Lake Superior Mining Institute. The first mill installed had a silix lining, but newer mills are lined on the straight face with pebbles set in grooves in steel plates. The conical faces are lined with silix blocks. Steel pebble linings have proved very satisfactory. A mill is out of service at least four days to replace silix lining, as the

cement must be allowed to set. With a steel-pebble lining, the mill can go into service again as soon as new plates are placed, a matter of hours only. So far, experience shows that the steel-pebble linings are cheaper. All the new mills will be equipped with the steel-pebble lining on the cones as well as the straight faces.

GLACIERS in Alaska have been studied by the United States Geological Survey, and in a report on the coastal glaciers of Prince William sound and Kenai peninsula by U. S. Grant and D. F. Higgins the following is in the summary: Some of the glaciers described, the Valdez, Shoup, Columbia, those of Port Wells and the Bear, have been under observation on several occasions during a period of 10 years. On the whole, the glaciers here studied do not give uniform evidence as to a general retreat or a general advance within the last half century; some are evidently in a period of retreat and others in a period of advance, and the general balance between retreat and advance can not be accurately determined by data now at hand.

SPUDS for gold dredges were at first made of wood, but with increasing size and weight of dredges, steel came into use. At first these were made of I-beams set parallel and bound together. Difficulties in repairing such spuds led to

STEEL SPUD FOR ALTA BERT DREDGE, TRINITY COUNTY, CALIFORNIA.

the development of a box-beam made of heavy steel plates. Such a spud was first built for the El Oro dredge at Oroville. A modern steel spud weighing about 20 tons is shown in the accompanying picture.

Gogo juice is universally used by the natives of the Philippine Islands in panning gold-bearing sand, and an investigation was made by the Bureau of Science. The native has for panning a large wooden bowl (*batea*), which is about 22 inches in diameter and slopes to a point in the centre like a flat inverted cone. The panner, usually a woman, has a little *gogo* bark at hand which at certain times she squeezes over the pan, causing the juice to fall on the water in the pan. It is believed that in this way more gold is recovered by causing the fine gold to settle quickly and not float away. *Gogo* is taken from the plant *Entada scandens* Benth. It is called *gogo* by Tagalogs and *bayogo* and *balogo* by the Visayans and Pampangans. The solution obtained from *gogo* is neutral, neither acid nor alkaline. Its chief constituent is saponin, a complex vegetable poison, which has a very slight acid reaction, and constitutes one of the groups of glucosides. These are generally colloids. In a summary of experiments on its effects on gold solutions, F. T. Eddingfield states that colloidal gold can be formed by (1) gold chloride, fresh *gogo*, and oxalic acid, plus heat; (2) gold chloride and *gogo* (after standing), plus heat; (3) gold chloride, *gogo*, and calcium carbonate, plus heat; (4) gold chloride, *gogo*, and sodium carbonate, plus heat; (5) gold chloride, saponin solution, and sodium carbonate, plus heat; and (6) gold chloride, saponin powder, and sodium carbonate, plus heat. The natives in Borneo also use the juice of certain plants to settle gold when panning gravel.

QUICKSILVER

The primary market for quicksilver is San Francisco, California, being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

ASBESTOS production in Russia continues to develop satisfactorily, and should gratify all those interested in the mining prosperity of the country. It was discovered in 1720 by Sophran Sorga and is found mostly in the Urals district, which is Russia's great mineral region, and in large quantities. The principal deposits are found on the western slope of this rising ground, and they extend over a great tract of country, beginning with the northern part of the Urals in the Bogosloff mining district. At the present time asbestos is produced mostly by the asbestos mines not far from the town of Ekaterinburg, which is the central metal-market town of the Urals. The deposits worked are largely situated in the estates of the Kamensk Treasury factory, Berezhoff, and Monetnoi. The production in 1912 was 1,007,679 poods,¹ and the value at the mine was 2 to 2½ rubles² 20 kopeks³ per pood. A great part of the Russian production is exported.

¹One pood = 36 lb. ²One ruble = 51c. ³One kopek = 1/2c.

COPPER EXPORTS

The Government figures for the first seven months of 1913 show the following exports of copper to European countries:

	Pounds.
United Kingdom	71,957,760
France	80,310,720
Germany	190,917,440
Holland	106,585,920
Belgium	3,097,920
Austria	19,535,040
Italy	26,232,640
Others	2,522,240

Total	501,159,680
Monthly average	71,594,268

GOLDFIELD CONSOLIDATED REPORT

During July the Company treated 29,550 tons of ore, yielding a net return of \$168,754, according to Albert Burch, the general manager. Operating costs were as follows:

Minling:	
Stoping	\$2.86
Development	0.68
Moving dumps	0.06
Transportation	0.08
Milling	1.91
Marketing	0.05
General expense	0.45
Bullion tax	0.04
Construction	0.03
Marketing ore shipped	0.71

Total costs	\$6.87
Miscellaneous earnings	0.04

Net costs

Development covered 3430 ft., at a cost of \$5.84 per foot. On No. 7 level of the Combination mine, the cross-cut was extended to a point 125 ft. east of the 414-D winze, where it cut what is believed to be the downward extension of ore previously cut by a diamond-drill hole. Where cut the vein was narrow, and, about the end of the month, driving was commenced for the purpose of prospecting a part of the vein more nearly in line with the drill-hole.

Near the end of the month the 135 cross-cut in the Mohawk mine cut the high-grade ore previously followed by the 127-X intermediate, and it will now be developed on the main No. 1 level instead of on the intermediate, which is only 20 ft. higher.

The 241 drift on No. 2 level of the Laguna mine followed a narrow vein of good ore throughout the month. This is in the hanging wall from the old 229 Bull Dog Fraction stope and may be the upward extension of the 303 J, O & P, which are the best producers in the Laguna.

The 901-E sill in the Clermont-Jumbo was slightly extended and produced 121 tons of \$14 shipping ore. The 916 cross-cut on the 1400-ft. level cut a strong fissure in the shale containing copper ore of too low grade to ship. It is probably the downward extension of the copper vein which has been so productive a few feet above; but it was cut in the Curley George claim, on which the Company holds a lease, and too close to the boundary line between the property and the Merger Mines claim to justify driving on it. Another cross-cut farther from the line will be driven to open it, and driving will be done in search of the shoot.

Commercial Paragraphs

GOLDSCHMIDT THERMIT Co. has moved its San Francisco office to 329-333 Folsom street.

F. W. Wetherill, formerly of New York, is now associated as engineer with the Seattle office of MEESE & GOTTFRIED Co., where he will give especial attention to elevating, screening, and transmission machinery.

THE HARDINGE CONICAL MILL Co., New York, reports that the Braden Copper Co. has placed its fourth consecutive order, amounting to twelve of the largest size Hardinge mills. When shipped this will make a total of thirty-six identical mills installed in the Chilean plant of this Company. The Cuba Copper Co., of Santiago, Cuba, has also placed an order for four of the largest size Hardinge mills for grinding in connection with the flotation process to be installed at its plant.

ON account of the rapid growth of business since the great San Francisco fire, the MEESE & GOTTFRIED Co. has been obliged to move its main offices in San Francisco from the old location at 55 Main street to the four-story steel-frame building at 660 Mission street, just back of the Palace hotel, where its engineering and sales departments will be better able to handle the many problems in transmission, elevating, conveying, and screening machinery, for the manufacture of which class of machinery this firm has the largest plant on the Pacific Coast. Branch houses and a complete stock are maintained at Vancouver, in British Columbia, Seattle, Portland, and Los Angeles.

THE S. FLORY MANUFACTURING Co. suffered the loss of a large part of its plant at Bangor, Pennsylvania, through fire recently, but reports that arrangements have been made to construct a new and up-to-date machine-shop, foundry, and necessary appurtenances as soon as it is possible to do so. In the meantime, temporary buildings will be erected and the necessary machinery installed to continue the manufacturing of engines, etc., with as little delay as possible. One building was saved from the fire. The foundry can be repaired in a short time to make castings for repairs and general construction of machinery within a very reasonable time, and no effort will be spared by the Company to provide facilities by installing the necessary machinery as promptly as possible.

EDITORIAL

A SINGLE shipment of silver bullion to London, recently made by the Nipissing mine at Cobalt, amounted to nearly 260,000 ounces, or about nine tons.

NOW that Sun Yat-sen has fled from China and William Sulzer, governor of New York state, has been impeached, the crooked promoter with an alleged mine can resume his wonted place in the limelight.

MINERS are to have a large part in National Conservation Exposition held at Knoxville, Tennessee, in September and October. A miners' field day is to be held September 20 and under the active supervision of Mr. C. H. Gordon, associate state geologist, an excellent display of exhibits relating to mines and minerals is being arranged.

RAND difficulties seem to have been smoothed over for the present, but the future is not altogether assured. The men would do well to note that mining on the Rand is at or near its high-water mark of prosperity. With lowering grades of ore, smaller profits, and, above all, with non-resident ownership of the mines, it seems probable that wages will decrease rather than the reverse. The white laborer on the Rand would do well not to rock the boat.

THE official call for the sixteenth annual session of the American Mining Congress has been issued. The Congress is to meet at Philadelphia, October 20 to 24, inclusive. Under the presidency of Mr. D. W. Brunton, and with the active assistance of a strong local committee, the meeting is certain to prove notable. A special feature of the occasion is to be an exhibit of instruments and appliances designed to promote efficiency and safety in mining. The nearness of the great anthracite mines will make possible a display of large interest to Western mine managers, who can easily learn much from their associates in eastern Pennsylvania.

WHILE selective mining is practised to a greater or less extent in the working of almost every type of metalliferous deposit, the degree to which this refinement may be conducted has been the subject of a great diversity of opinion, especially among Rand operators. The range of opinion there is all the way from supporters of an extremely large tonnage of comparatively low-grade material, to those who favor a practice which amounts to high-grading the mine as fast as ore of first class can be developed. Arguments can be found in favor of both extremes, but each property presents its own problems and there is, within limits, opportunity to choose that

degree of selectiveness which, when applied to the particular case, will produce the best economic results. In discussing Mr. Owen Letcher's article on 'Rand Conditions and Future Outlook,' Mr. H. S. Denny presents elsewhere a most interesting analysis of the principles of selective mining. As Mr. Denny was actively connected with the management and engineering problems of one of the Rand's largest groups for a number of years, he is particularly well qualified to treat this question.

TELLURIDES form a group of minerals which while rare are of large economic importance. In view of the small notice given to them in many textbooks of mineralogy, we are glad to print this week the detailed notes of Messrs. Malcolm MacLaren and J. Allan Thomson. This closes the series of informing articles on Kalgoorlie to which the profession is indebted to these gentlemen. We shall shortly begin publication of an equally authoritative account of the Rand, written by Mr. C. B. Horwood, who has devoted ten years to the study of this the world's greatest goldfield, bringing to the task not only careful scientific training, but the thorough experience of a mine manager who has served his apprenticeship in subordinate positions.

The Administration and Mexico

Although the administration's statement of attitude toward Mexico has been the subject of no little criticism both at home and abroad, it is to be noted that there has been no better policy suggested by any of those dissatisfied with the course which has been followed since the beginning of the present controversy. The administration's treatment of the situation is to be generally commended, and the absence of jingoism from both houses of Congress, with the exception of that one lonely voice from the Senator from Pennsylvania, is evidence of the unanimity of the belief in the President's policy and the wisdom of his course. To those familiar with the ways of the Latin, it was to be expected that President Huerta would reject any proposal coming from the United States; but ~~now~~ when there has been time for reflection, it is not at all improbable that Don Victoriano will awake to the realization that the American people are Mexico's best friends and that our motives have been solely altruistic. As the situation stands, there are but two available policies, the present policy of diplomatic solution of Mexico's difficulties and the alternative of an armed intervention. The latter course is untenable under existing conditions and could only be sanctioned as a very last resort. While the ultimate result of such a conflict is assured, there could be nothing gained by such a move, and another addition to the 'white man's burden' is by no means an asset. The United States has domestic problems of greater import which demand attention and while it is our duty to protect American lives and investments in Mexico, it is also our duty not to engage in a warfare which, judging from the war with Spain, would cost a large number of lives and from half a billion to a billion dollars, except as a last resort. American investments together with those of foreign nations have

suffered and are suffering from the present revolution in Mexico, but a resort to arms at this time is by no means warranted and might easily result in still more serious consequences and a paralysis of industry in that country which would take years in righting itself.

The Institute and the Society

One of the amendments to the constitution of the American Institute of Mining Engineers, which was adopted at the annual meeting last February, authorized the directors to arrange for affiliation of other technical societies. This amendment was adopted with full knowledge that among the affiliations contemplated was one with the Mining and Metallurgical Society of America. Indeed, at the meeting, Mr. J. W. Richards, chairman of the committee on amendments to the constitution, stated that in view of the pending plan of union of the Mining and Metallurgical Society with the Institute, the proposed amendment providing for a class of 'Fellows' of the Institute was unnecessary and undesirable, and advised a vote against it. The amendment was thereupon voted down by means of a block of proxies, though the general vote of the membership is said to have been favorable. This would seem to make it clear that so far as the whole membership of the Institute expressed any opinion it was not adverse to a classification of membership, and that the particular plan proposed by the 'Fellowship' amendment was defeated in view of plans already contemplated, for affiliation of the Mining and Metallurgical Society. The vote in favor of the new constitution delegating to the directors authority to effect affiliations was clearly taken with a view to the particular affiliation mentioned, and one or two others that had been also discussed. Negotiations for affiliation were therefore resumed through duly appointed committees of the governing bodies of the two institutions. In due time a plan of union was agreed upon. Whether or not this was the wisest plan is, we think, beside the question. It was the only practicable plan upon which the two committees were able to agree. As is true of all compromise agreements, it was unsatisfactory in part to each party to it, but in our judgment, in case it had been carried out, it would have afforded a working basis, and the spirit of harmony would have been more effective than any technical or formal obstacles standing in the way of complete union.

The constitution of the Mining and Metallurgical Society contained no provision for affiliation, as did that of the Institute, nor had the membership of the Society, as had that of the Institute, voted upon the principle involved. The Council of the Society, therefore, endorsed the plan and also obtained a favorable referendum vote of the members. Not only was this done, but the Council obtained authority upon the effecting of the affiliation, to offer membership in the Society practically without restriction or formality to all those members of the Institute who, by reason of experience and professional attainments clearly specified in the constitution, were eligible. A rough calculation will

make it clear that this plan would have made 500 to 1000 members of the Institute immediately eligible. Carrying it out in good faith would have given potential control of the Society to those who at present are non-members. There can be no question of the absolute good faith of the Society and its members in this matter, and therefore talk of the Society becoming a small inner clique to control the Institute is nonsense. The Institute is, and always will be, dominated by its strong and capable members, as it should be. The men who know how to lead do lead, and under the proposed plan the men who have the professional qualifications demanded of members of the Mining and Metallurgical Society, some of whom are members of it and some of whom are not, would have dominated the Institute by force of ability, as they do now.

At the time of these negotiations and up to a recent date there was no hint that the directors of the Institute were not authorized to make the agreement outlined and there was no indication that they would not endorse the action of their own properly appointed and especially capable committee. The Society accepted the report in good faith and even went so far as to amend its constitution in order to carry out the plan of union. Now the directors of the Institute have voted as follows:

"The board of directors of the American Institute of Mining Engineers has carefully considered for several months the question of union or affiliation with the Mining and Metallurgical Society of America, and while at an earlier time and under other circumstances such a union might have been accomplished, yet under present circumstances, the directors of the Institute deem such union inexpedient. While thanking the Mining and Metallurgical Society of America for its consideration of the matter, we believe that further discussion of the subject will serve no useful end, and we conclude it best that the Society and the Institute continue their useful functions and friendly relations side by side as heretofore."

It becomes a pertinent question as to what are the changes of circumstances that warrant the directors in backing out of an agreement so nearly concluded; one, moreover, that resulted from negotiations initiated on its side. Clearly the significant change is the regeneration of the Institute itself and the belief that it is now in position to undertake, in addition to the work it has long and excellently accomplished, the new responsibilities neglected for years by the Institute and first undertaken by the Society. The most important of these are: (1) creation of a means of ascertaining and expressing the opinion of the profession on public matters touching mining; (2) formation of local sections to stimulate interest and promote friendly coöperation. The third major activity of the Society, the creating of a definite standard of conduct and attainment as a basis for membership, the Institute frankly abandons. The Institute is endeavoring, through large committees, to find a means of ascertaining and expressing the opinions of its members on various subjects. Whether in the end this method will prove as effective as that of committee action followed by referendum vote developed by the Society, is fairly

an open question. As to that, time will tell. In the matter of local sections it needs but little consideration to make clear that any section built on the large and miscellaneous membership of the Institute must be very different in character from the sections of the Society and must find its field in the reading of papers, giving of lectures, and similar activities rather than the friendly, informal, after dinner meetings of the Society. The matter of standards of membership is, we think, too important for a great profession to ignore permanently, and the only way to create and maintain a standard is by voluntary affiliation in some organization of those who are eligible. How the Institute is to meet this problem without the help afforded by the Society as a nucleus, is far from clear; and, recalling the history of the formation of the Society, it is even less clear how the action of the directors of the Institute in rejecting the plan of affiliation is going to promote that spirit of harmony and friendly relations, that all would like to see obtain. To our way of thinking, rejection of the agreement was a mistake. Those directors who felt they could not vote favorably should, we think, have made their influence felt earlier. Practically, if not technically, the action of the board savors of repudiation.

We feel keenly that it would be better for the profession to have one society rather than two, and we regret greatly that there seems no immediate prospect for bringing about that condition. As good democrats, and "forward-looking men" we are more concerned with the future than the past, and it is evidently to be a period for repressing any disposition to criticize uselessly, however natural it may be. The men of the Mining and Metallurgical Society will, of course, maintain their organization and keep up their work. No other course is open to self-respecting engineers such as constitute its membership. The Society, while small, is influential, and every effort should be made to make it most effective. It is not impossible to maintain small professional societies with low dues, where their purpose is sound and their leadership wise. Something over a quarter of a century ago it became evident that the large and miscellaneous membership in the geological section of the American Association for the Advancement of Science did not afford a sufficient bond among professional geologists. The Geological Society of America was therefore created and, with a limited membership, it has attained a position of conspicuous usefulness and influence. The secret lies in the fact that it has maintained a high standard of membership and of work. It is a real honor to be a member of it. Incidentally, out of dues of \$10 per year and a low initiation fee, it has published an excellent series of bulletins and has accumulated a satisfactory reserve fund. The life of a society is conditioned by its usefulness. Let it serve a high purpose diligently and it may be sure of success and the respect that success brings. We counsel the members of the Mining and Metallurgical Society to look at the situation with good humor and to persevere in their efforts to place the profession of mining engineers on at least as high a plane as that of the civil engineers and of the great learned professions.

Mining by Wholesale

By THOMAS T. READ

Progress in the mining of copper and gold ores tends steadily toward the mining of large low-grade orebodies by wholesale methods, thus minimizing operating costs. As a result, metal mining comes more and more to resemble quarrying, and in the best and cheapest methods of quarrying work the metal miner may find much that is suggestive and useful. The following description of the quarry and crushing plant of the Tomkins Cove Stone Co., Tomkins Cove, New York, which is commonly accepted as the largest stone-crushing plant in the world, follows closely a description which appeared in *The Excavating Engineer*, December 1912, only such corrections having been made as were neces-

About 160 men are employed, including farm hands, etc. The quarrying work is done in hard blue or gray limestone which rises to a height of 200 ft. above the Hudson river.

The limestone is blasted from a high vertical quarry face, loaded by Bucyrus steam-shovels to cars on a high level track, and drawn an average distance of about 800 ft. to the top of the crusher house. It is dumped directly into the crusher hopper and passes vertically downward through three successive sets of horizontal crusher rolls, which reduce it to a maximum size of about 2 in. From the lower rolls it is raised about 90 ft. by a steeply inclined steel pan elevator which discharges into a hopper in the top of the preliminary screen-house. This hopper discharges into a distributor that spreads the broken rock evenly over a gravity screen that removes all stone larger than $1\frac{1}{2}$ in. and delivers it to a belt conveyor by which it is returned to the last pair of rolls.

About 90% of the product which passes through the preliminary screen is delivered by a belt conveyor 362 ft. long, inclined about 10° to the top of the main screen-house, where it passes by gravity vertically through a stationary distributing and screening apparatus which separates it into $1\frac{1}{2}$, $\frac{3}{4}$, and $\frac{3}{8}$ -in. sizes, each of which is discharged on a separate horizontal belt conveyor and dumped into one of the five storage-bins with a combined capacity of 20,000 cubic yards.

Loading Capacity

The loading capacity is at present about 600 yd. per hour. Both loading and shipping capacities can easily be largely increased at any time by the use of wider belts on the present conveyors.

The conveyor-galleries, supporting trestles and towers, and the roofs, beams, girders, and columns of the crusher and screen houses and power-house are of structural steel, sheathed with corrugated iron and furnished and erected by the Snare & Triest Co. All floors are of concrete, all foundations on solid rock. Excepting the steam-shovels, locomotives, and the main jack-shaft operating the crusher roll, all of the equipment is operated by separate electric motors of Allis-Chalmers make, and all electric wires that otherwise would be dangerously exposed are run in pipe conduits.

At present the stone for the new plant is taken wholly from the upper bench of the quarry, since its floor is at the same level as the receiving platform of the crusher house.

The face of the upper bench of the quarry is about 140 ft. high and 700 ft. long, and is worked by full-depth holes of a uniform diameter of 6 in. These are drilled by three Keystone and two Clipper drills operated day and night by two men each.

TOMKINS COVE STONE QUARRY AND PLANT.

sary to cover recent changes. An excellent description of the plant as originally designed appeared also in *Engineering News*, January 12, 1911.

Certain of the illustrations used in the articles are here reproduced, and to them are added halftones from photographs kindly furnished by the Stevens-Adamson Company.

Income and Expenditure

The most interesting part of this work to the miner, namely, the cost of the different steps of the work, is unfortunately not available for publication, since the Company is privately owned and is unwilling to disclose its operating costs. It may be stated, however, that the product, crushed limestone (of three sizes, $1\frac{1}{2}$, $\frac{3}{4}$, and $\frac{3}{8}$ -in. ring), is sold f.o.b. railway cars and barges at the plant at the average rate of 75c. per cubic yard or 57c. per ton, the crushed rock averaging 2600 lb. per cubic yard. From this average return, all operating costs, overhead charges, and general expense must be met, and a good operating profit is made. The plant has a capacity of 8000 tons in a 10-hour day. Ordinary laborers are paid at the rate of 20c. per hour, and skilled workmen higher wages; steam-shovel operators, for instance, receiving \$150 per month. The low rents paid by the workmen who live in Company houses may also be regarded as a part of their wages. Comfortable small houses of four to five rooms are rented for 57 to 76c. per week, according to their size and desirability.

The holes are about 8 ft. apart in rows 30 ft. back from the face of the quarry, and are each charged with from 400 to 600 lb. of 60% dynamite, chiefly furnished by the Du Pont de Nemours Powder Co., and are fired in groups of 5 to 6.

In blasting, as many as 56 holes have been fired at one time, using 6 to 10 tons of powder in 85 or 90-ft. holes. Under the management of William Lange, now in charge of the quarry, the firing of giant blasts has been introduced with good results. Small adits are driven into the quarry face, turned off at right angles, and the powder stowed at the end of the drifts and at intervals along their

Iron Works, and are drawn by 40-ton American Locomotive Co. locomotives to the crusher house. There are also three Shay locomotives to handle the ears on the $4\frac{1}{2}$ to 5% grades that are used in some places. A new design of car carries three such skips on one frame, the longer wheel-base thus afforded resulting in fewer derailments and consequently greatly lessened repairs and lost time. The lost time of the shovels, on account of 'spotting' ears and the other ordinary delays, amounts to about 50 to 55% of the total time. There are in the quarry and around the plant about three miles of standard-gage track laid with 80-lb. rails.

ISOMETRIC VIEW OF CRUSHER HOUSE.

length; as much as 22 tons of Judson powder and 60% nitroglycerine being used in one blast, resulting in breaking down 250,000 cu. yd. of rock. Some interesting work is being done in the driving of these adits and cross-cuts, which are roughly oval in cross-section and not large. The driving is done by contract at the rate of \$2 per foot of advance, the Company furnishing powder, tools, and electric light. One man and his helper, working 10 hr., advance 6 to 7 ft. on the average, and have made as much as 9 ft. in 10 hours.

Quarrying Operations

The limestone is shattered into irregular pieces, roughly cubical, nearly all of which are within the capacity of the three 95-C Bucyrus steam-shovels, having $4\frac{1}{2}$ -yd. dippers. The shovels load the stone into 8-yd., $6\frac{1}{2}$ by 9-ft. steel skips, $4\frac{1}{2}$ ft. deep, manufactured by John Turls Sons, Newburgh, New York. The skips are set on separate steel-frame standard-gage cars manufactured by the Pamapo

The loaded skips are delivered at ground level in the upper story of the crusher house on both sides of the first rolls. They are unloaded from the cars by a counter-weighted whipline led over a sheave in the roof and thence to a Lidgerwood hoisting engine. The skip is dragged to the receiving table, where its forward lower edge engages a stop against which it is revolved upward to dump its contents into a vertical-sided hopper made of heavy ribbed sectional cast steel plates with a 7 by 9-ft. rectangular opening to the rolls.

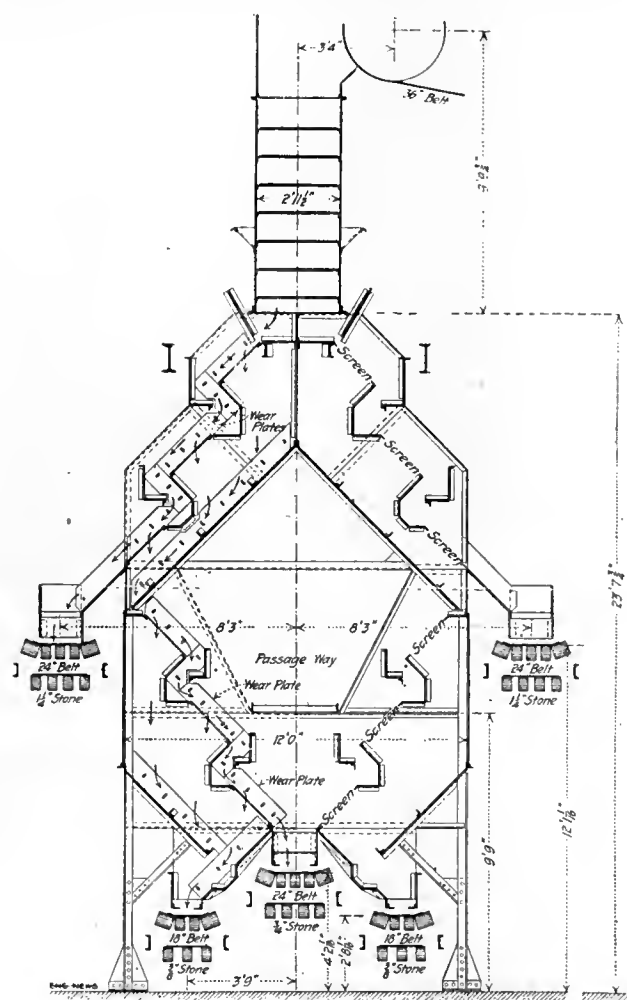

Roll Crushing

Any stone which can be loaded in a skip or handled by a shovel is crushed by the Edison rolls, which reduce a 9 by $4\frac{1}{2}$ by $4\frac{1}{2}$ -ft. hard stone to 6 or 8-in. pieces in 10 seconds. Sometimes larger pieces are chained and loaded, and when by accident a piece is delivered which is too large to pass through the opening, or jammed diagonally, a short hole is quickly drilled in it by a pneumatic tool

and a light charge of dynamite fired without removing it from the bin. This breaks it enough to enable it to drop into the rolls, and it is immediately crushed without difficulty or injury to the machinery and with very little loss of time. Under ordinary conditions, 8 cars can be dumped in 6 minutes.

Power-House

The 60 by 123-ft. power-house on the second bench of the quarry, close to the vertical face of the rock, has a trussed roof about 20 ft. high in the clear.

SIDE ELEVATION OF SCREEN USED FOR FINAL SEPARATOR.

and is divided by an interior row of columns in two parts with separate double-pitched roofs and monitors. In the 43 by 60-ft. boiler-room there is a battery of three 600-hp. Heine boilers, with room for one more; two 12 by 8 1/4 by 12-in. Davidson single-acting feed pumps, and a Cochrane water heater and purifier. Two boilers supply all the steam at present required, leaving the third always in reserve. A sidetrack from the boiler-house to the main line of the West Shore railroad and an elevated coal storage-bin with automatic feed to the boilers has been provided.

Engine-Room

In the 60 by 80-ft. engine-room there is installed a heavy-duty cross-compound 18 by 36 by 36-in. condensing engine of the Reynolds type direct-connected to a 500-kw. generator furnishing 500-volt, 25-cycle, 3-phase current for all electric light and power throughout the plant. There is also installed a

1000-hp., heavy-duty, cross-compound, 22 by 44 by 42-in. condensing engine of the Reynolds type, connected to a 15-in. jack-shaft 36 ft. long, with two double-face pulleys, 10 ft. diam., belted to the Edison crusher rolls.

Condensation water is pumped from the river through a 10-in. spiral-riveted pipe by a centrifugal pump driven by a 30-hp. motor, and is returned to the river through a pipe of the same diameter. There is also in the engine-room a large Ingersoll-Rand air-compressor, and the usual complement of oil separators, traps, filters, and a gravity oiling system. The engines and generators were installed by the Allis-Chalmers Co., Milwaukee, which also furnished all of the 13 motors, from 15 to 150 hp., which are required in different parts of the plant for the separate and independent operation of all the principal items of the machinery.

In order to pass the stone by gravity through the sets of crusher rolls, the latter are arranged in a vertical line between the levels of the floors of the second and third benches of the quarry. The skip-dumping machinery and the lubricating oil reservoir are placed in the roof of the crusher house, and the rolls are supported on very heavy steel girders.

Crusher House

The general arrangement is indicated in the diagram. The rolls are of the Edison type, designed by the Edison Crushing Roll Co. The first or upper pair of rolls, 6 ft. diam. and 7 ft. long, are run at 180 r.p.m. and will crush the stone much faster than it can ordinarily be delivered. They are set about 6 ft. 6 in. apart on centres and have forged steel mandrels about 5 ft. diam., to which are cap-bolted 16 half-length segmental surface plates of chilled east iron, 6 in. thick, with projections or spurs about 3 in. long. On one of the rolls are two diametrically opposite longitudinal rows of spurs 6 in. long, which act as sledges to break the rock which is crushed between the other spurs.

Horizontal feed rolls 30 in. diam., and both operated by a 15-hp. motor, are set, one on each side of the opening in the feed tube, and a pair of full length distributing rolls, 30 in. diam., are placed in the bottom of the receiving hopper, so as to deliver its contents more uniformly to the second pair of rolls 13 ft. vertically below the first pair. These are 4 ft. long and 4 ft. diam., and of similar construction to the first pair. They are arranged to deliver to either of two pairs of finishing rolls several feet below them, which are 4 ft. long and 3 ft. diam., with corrugated surfaces instead of spurs. Only one pair of the corrugated rolls has been installed, but provision is made for the installation of a second pair if necessary, thus making the plant symmetrical and delivering broken stone on both sides of the centre line to the pan conveyor.

The rolls are enclosed in riveted steel hoods hinged on their upper edges and lifted by tackles provided for the purpose. All of their bearings are flooded with oil in dust-proof iron boxes and the oil from a 500-gal. reservoir in the roof of the building is distributed through pipes and sight feeds to the bearings and collected from them in pipes which

deliver to a 600-gal. drain tank in the basement. From this tank the oil is forced by a Davidson vertical triplex pump through a filter and back to the roof tank, thus providing for constant circulation and purification of the oil at a minimum loss.

The product of the rolls is elevated 83 ft. by a 45° pan conveyor, said to be the largest yet constructed, with 116 triangular 72 by 30-in. riveted steel pans 2 ft. deep, with a capacity of about 1000 lb. each. This conveyor is operated by a 150-hp. motor at a speed of 87 ft. per minute and carries 1000 yd. of broken rock per hour. All the other conveyors, which with this exception are of the belt type, manufactured by the Stephens-Adamson Manu-

though the provision here described permits it to be quickly and easily changed if necessary. The screen plates are of commercial manufacture and can be quickly replaced when necessary, but they show such durability that it is believed that the use of ordinary steel will be continued instead of manganese steel, which would cost about four times as much.

Course of Rock Through Screens

The material passing over the first screen strikes a right-angle steel shelf just below it and covers the same with a cushion of broken stone which protects the surface of the steel and soon acquires a permanent slope on which all the succeeding material stops

LOADING CARS AT THE QUARRY.

facturing Co., Aurora, Illinois, are operated by separate electric motors.

Sizing Screens

The pan conveyor discharges into the hopper of a fixed gravity screen which separates the broken stone into two sizes, one of which contains pieces above 1½ in. and the other contains everything below 1½ in. These screens are Edison patent and have a number of comparatively long and narrow inclined shelves over which the broken stone falls in a sort of cascade with its velocity checked at each step, so that all of the screens are efficient.

The screens are arranged symmetrically inside a steel plate shell, and the two sets, each with a total area of 96 sq. ft., are separated by a central vertical diaphragm enabling either or both sides to be used at will. The removable screen plates, 2 ft. wide, are made in sections 4 ft. long, of thin carbon steel plates punched with square holes and are set at an angle of about 40° with the horizontal.

The efficiency of the screen is very sensitive to changes in the character of the material or in the amount of moisture which it contains and to the degree of inclination of the screen, therefore the plates are made adjustable by the insertion of shims, up to ½ in. thick, under the lower edges. Extended experiments were made before the installation of this screen and resulted in the determination of the 40° angle, which will probably be maintained, al-

and then falls again to the next screen, from which it is deflected to a second shelf, and so on, this stopping at every step and zigzagging down from top to bottom at a moderate velocity.

The large stones rejected by the screens are discharged from their upper surface to a 24-in. belt conveyor 92 ft. long, driven by a 10-hp. motor, and are returned to the finishing rolls.

The remainder of the stone, passing through the screens, is caught on an inclined bottom plate provided with transverse angles which check the speed of the stone sliding down over it to a second chute delivering to a 36-in. belt conveyor 362 ft. long that is inclined about 10°, driven by a 100-hp. motor, and has a capacity of about 800 yd. per hour. It discharges its burden to the receiving hopper in the top of the main screen house about 60 ft. above the point of delivery.

This hopper delivers to a distributor, which is a steel-plate box containing two inclined tiers of narrow horizontal shelves on which the broken stone falls and accumulates in full-width heaps with sloping sides, over which the succeeding pieces slide and fall in sheets on both sides of each shelf, thus equally distributing the crushed rock over the screen plates below. The shelves, 3 ft. long and 12 in. wide, are provided with rack and pinion connections which give them horizontal motion in either direction so that they can be adjusted if necessary to suit changing conditions.

From the distributors the broken stone passes through an 8 by 12 ft. rectangular box, about 23 ft. high, in which there are installed, on each side of the centre line, three successive sets of screens of the same type as those described in the preliminary screen house. The screens are symmetrical on each side of the centre line and each half, having a total screening surface of 192 sq. ft., can be used independently of the other and is designed to be served by two belt conveyors on each side, besides a fifth conveyor on the centre line which receives the $\frac{3}{4}$ -in. stones from the screens on both sides.

Advantages of the Screening System

This method of screening is considered by the owners to be more rapid, efficient, and economical than the use of revolving screens and is believed by them to possess a great advantage over that method, in that much less dust is produced and the sharp corners of the stone are not broken off as is the case when it is revolved in a cylindrical screen. The screens are completely enclosed, they are made of commercial plates easily secured, replaced, and adjusted, the installation is compact and convenient, and most of the steel work excepting the screen plates is protected from wear by cushions of broken stone, thus greatly increasing its durability.

The $1\frac{1}{2}$, $\frac{3}{4}$, and $\frac{3}{8}$ -in. sizes of broken stone are respectively delivered from the screens to 30, 24, and 18-in. conveyor belts, 120 ft. long, on centres that are driven with a speed of 400 ft. per minute and discharge their burdens to corresponding horizontal 30, 24, and 18-in. belts, 140, 210, and 275 ft. long respectively, all of which are driven at a speed of 300 ft. per minute by separate 20, 15, and 10-hp. motors. They are at right angles to the first set of belts and carried through an elevated gallery over the tops of the storage bin, about 65 ft. above its floor, discharging at any point of any bin by means of standard automatic trippers.

The storage bins have a common horizontal concrete floor, 40 ft. wide and 292 ft. long. On it there are seated five reinforced concrete transverse partition walls, 48 ft. high, which separate it into an outside extension, and four independent bins enclosed by a vertical wall, 32 ft. high, on one longitudinal side, and by the vertically excavated rock face of the bluff on the opposite side.

Belts

The widths of the belts are proportioned to the different quantities of stone produced by the crusher, namely, 56% of $1\frac{1}{2}$ in., 30% of $\frac{3}{4}$ in., and 14% of $\frac{3}{8}$ in. As the demand for different sizes of stones varies with different seasons, considerable flexibility is required for the storage system, and one bin is reserved for $1\frac{1}{2}$ -in. stone exclusively, another for $\frac{3}{4}$ -in., and two for $\frac{3}{8}$ -in., which is more likely to accumulate, and one large bin nearest the screen house is kept available for any size required.

In the floor of each bin there is a row of 18 by 24-in. holes, 10 ft. apart on centres. Each hole is provided with a steel quadrant valve operated by a lever in the tunnel below. When stone is required for shipment, two valves are usually opened and discharge the stone on a 36-in. horizontal belt 291 ft. long, which is operated by a 50-hp. motor and runs

from end to end of the tunnel at a speed of about 400 ft. per minute with a capacity of 10 yd. per minute.

This belt delivers to an inclined 36-in. conveyor belt 170 ft. long, run by a 50-hp. motor at a speed of 350 ft. per minute, which elevates the stone to a height of 27 ft. above the ground and discharges into a hopper with transverse chutes on both sides through which the stone may be loaded into cars on the railroad track below, and also with a longitudinal chute through which, if the transverse chutes are closed, the stone may be delivered to the last conveyor, which has a 36-in. belt 240 ft. long, run by a 50-hp. motor at a speed of 400 ft. per minute, to the end of the dock, where it terminates about 28 ft. above water-level with a hopper provided with a telescopic steel chute 20 ft. in maximum length. This can swing 180° , is supported at the outer end by a boom and tackle, and is thus enabled to reach any part of the 500 or 600-yd. barges moored to the front or side of the dock.

Magnitude of the Plants

About 15,000 cu. yd. of concrete and 700 tons of structural steel was used in the construction of this plant, which was designed and constructed by P. K. Yates, following general plans prepared by the Edison Crushing Rolls Co., Stephens-Adamson Manufacturing Co., Allis-Chalmers, and others. The quarry has been in the hands of the Tomkins family for 75 years, reaching its present stage of development under the administration of Walter Tomkins, president of the Tomkins Cove Stone Company.

The Lovett Grinder

The Winona Copper Co., after extensive experiment with the Lovett grinding machine, has decided to make a trial installation. The machine consists of two cast iron disks running face to face in a horizontal plane. The bottom disk rotates about its axis, while the top disk reciprocates across the face of the bottom disk. The material to be ground is fed through a hole in the top plate. The top plate is made in sections, secured in a harness, which maintains contact with the lower plate simply by their own weight. Some middling on which an extraction of 29% in direct mineral was usually obtained was treated in this machine. After grinding in the Lovett machine an extraction of 71% in direct mineral was made. The feed going to this machine contained 34% of material through 200 mesh (ordinary number 24.4) and the product contained 63% through 200 mesh (ordinary number 26.4).

Official figures show the following output from Charters Towers, Queensland, for the month of May. Mills crushed 6537 tons yielding bullion 4745 oz., value \$77,000; cyanide works treated 9206 tons, yielding bullion 5223 oz., value \$38,400; smelters treated 276 tons yielding gold 1640 oz., value \$33,600; silver 2200 oz., value \$1050; lead 21 tons, value \$1480; alluvial gold 15 oz., value \$310; copper ore 2 tons, and copper concentrate 17 tons, yielding bullion valued at \$115; silver 40 oz., value \$19; copper $3\frac{1}{2}$ tons, value \$2232; black tin, value \$31; slag 15 cwt., value \$210; the total value being \$154,463.

The Re-Awakening of an Old Placer Camp

By ERNEST G. LOCKE

Twenty years ago American cañon, in Humboldt county, Nevada, was the scene of great activity. Hundreds of Chinamen were working the gravels, and recovering millions in gold dust, of which fact ample evidence remains in the hundreds of shallow shafts, and the piles of worked gravel spread over not less than two miles of the river-bed. The first discoveries were probably made by white men, but they proved indifferent to the riches at their hands, so the ground was leased to a Chinaman on a royalty basis. It is said that this Chinaman brought in hundreds of his countrymen to whom he sub-let the ground in blocks 20 ft. square. Each lessee sunk a shaft to the pay-streak and mined out the ground comprised in the lease. Thousands of piles of tailing attest the energy with which work was conducted. An old Chinaman still living on the ground—the last of five hundred—states that each block of ground 20 ft. square produced from \$1500 to \$3000 in gold dust and nuggets. The source of the gold has not been definitely traced, but it is believed to have originated in a range of porphyry hills through which the old river cut its bed, and the remains of which can now be examined still carrying gold contents varying from a trace to \$15 and \$20 per ton. In my mind, there is no doubt that these porphyries provided the placer gold of American cañon, and of the several other cañons lying north and south, which also produced the yellow metal.

Production of American Cañon

It is a difficult matter to endeavor to make an estimate of the aggregate amount of gold taken out of American cañon. Chinamen are secretive as to their gold, but it is said that the Wells Fargo & Co. Express has a record of several millions of dollars worth carried out by it. F. L. Ransome gives a reported output of ten millions, and others believe twenty millions to be nearer correct. However, it is certain that the extraction has been good from an area represented by only two miles of river bed, which was the extent of the gold-bearing gravels.

In working the gravels down the river the bedrock was porphyry up to a certain point, where it changed to limestone. The pay-streak lay on a false bedrock of clay, generally about 60 ft. from the surface, being shallower at the upper end of the diggings and increasing in depth at the lower part. A shaft nearly 200 ft. deep was sunk through gravels to the limestone. The pay-streak, however, still retained its position at about 70 ft. from the surface; little or no gold was found below the false bedrock, and none on the limestone.

About half a mile below this shaft the gold spread into a fan-shaped deposit and gradually was lost. The cañon continued, so why did not the gold? It is believed by many that the lower part of the old channel with its gold gravels was faulted and carried northward for about 2000 ft., the upper portion being tilted up to a steep angle. Some time after

this occurrence a flow of lava came from the mountains to the west and filled and concealed this faulted part of the channel.

This portion of the gold river channel, unnoticed by a generation of prospectors, has recently been discovered, through portions of the gravel having rolled down the hillside from under the lava. There can be no doubt of it being an old river channel—the north rim of the channel (limestone) is visible in several places, but the south rim is buried under the lava; in between, the gravel outcrops at one point, and has been uncovered at several places by pick and shovel. A shaft, now down 130 ft., is projected to go to bedrock, and a tunnel is being driven under the lava toward the south rim. All of this work is in washed gravel, sand, and boulders—pannings show that the gravel contains fine colors of gold, some cinnabar, plenty of magnetite, and cubes of hematite; in fact, the porphyry gravels are exactly the same as those worked by the Chinamen in American cañon, there can be no doubt that the same hills were the source of both.

Such being the conditions, it is confidently anticipated that when bedrock is reached and the old river channel cross-cut from rim to rim, rich returns will be had.

American cañon is situated a short distance from the new camp of Rochester, the head of the cañon being no more than one mile north of Newel hill; the diggings are about three miles down the cañon, and many now look forward to seeing there the life and battle of a successful gold district.

Operation of the Great Boulder Mill

From the annual report of this Kalgoorlie company, the following is abstracted:

During the year 1912, a total of 193,451 tons (2240 lb.) of sulpho-telluride ore was treated in the sulphide mill for a return of 59,284 oz. of bullion by amalgamation, worth approximately £213,924, and 98,249 oz. of bullion by cyanidation worth approximately £354,850. Also treated 14,467 tons of old tailing for 1204 oz. of bullion, worth approximately £4385, making a total for the year of 158,738 oz. of bullion produced, worth approximately £573,159.

The loss of mercury per ton of ore treated in the sulphide mill has averaged 0.178 oz. The loss of cyanide has been 0.9 lb. per ton of ore treated.

The average assay value of the residue of the ore treated during the year is 1.60 dwt. per ton of 2240 lb., and the average assay value of the residue of the old tailing dump is 1.37 dwt. per ton. Costs were \$1.92 in the sulphide mill and 82c. per ton in the cyanide plant, a total of \$2.74 per long or \$2.44 per short ton.

Dividends paid by gold mines on the Rand during the first half of 1913 total \$19,200,000, while those from outside districts, diamond, coal, and tin mines made a total of \$21,600,000.

During the month of July the Elmore vacuum plant, at the mines of the Sulitjelma company, Norway, produced 850 tons of copper concentrate.

Geology of the Kalgoorlie Goldfield—V

By MALCOLM MACLAREN and J. ALLAN THOMSON

Kalgoorlie is not rich in variety of vein minerals, nor are good crystals of the rarer species often obtained. In rock-forming minerals, however, it is well represented. The following list gives the species that have been noted by us, or recorded by previous observers.*

Actinolite	Coloradoite	Melonite
Albite	Dolomite	Mesitite
Altaite	Emmonsites ¹	Muscovite
Amalgam ¹	Enargite ¹	Olivine
Amphibolite	Epidote	Opal ¹
Apatite	Fahlore	Orthite
Arsenopyrite	Fluorite ¹	Pennine
Asbestos	Fuchsite	Petzite
Asbolite ¹	Galena	Psilomelane
Augite	Gold	Pyrite
Axinite	Graphite	Pyrrhotite ¹
Biotite	Gypsum	Quartz
Blende	Halite	Rhodochrosite
Bornite	Hematite	Rickardite
Bournonite ¹	Hessite	Roscoelite
Breunnerite	Ilmenite	Ruby silver ore ¹
Calamine	Kaolin	Rutile
Calaverite	Krennerite ¹	Scheelite ¹
Calcite	Leucoxene	Sericite
Cerargyrite	Limonite	Serpentine
Chalcedony	Lollingite ¹	Siderite
Chalcopyrite	Magnesite	Silver ¹
Chloritoid	Magnetite	Sphene
Chromite	Malachite	Sylvanite
Cinnabar ¹	Marcasite	Talc
Clinochlore	Massicot ¹	Tourmaline
Clinozoisite	Melanterite	

Mode of Occurrence

The minerals may be classified by mode of occurrence under five heads.

1. Those which constituted the original igneous rocks. Olivine, augite, basic plagioclase, and orthoclase (if any) have totally disappeared. Apatite, chromite, magnetite, titanomagnetite, ilmenite, brown and green hornblende, biotite, acid plagioclases, and quartz are still found.

2. Those formed by a rearrangement of material during rock alteration with or without the addition of water and carbon dioxide. They are sphene (including leucoxene), rutile, hematite, magnetite, serpentine, talc, hornblende (uralite), biotite, chlorite, chloritoid, epidote, clinozoisite, zoisite, muscovite (sericite), carbonates, and quartz.

3. Those occurring in 'segregation veinlets' in the altered rocks, consisting for the most part of the minerals produced during the alteration. The composition of the veinlets may be tabulated as follows:

Rock.	Minerals of 'Segregation-Veinlets.'
Amphibolites.	Epidote; quartz and epidote.
Contact-altered amphibolites.	Epidote; quartz and epidote, with actinolite and biotite.
Serpentines.	Serpentine and chalcedony.
Carbonated serpentines.	Carbonates and quartz.
Older Greenstones.	Quartz, carbonates, and chlorite.

*Only the occurrence of gold and of the tellurides will be here described in detail.

¹Not observed by the authors.

Older Greenstones
(Calc-schists).

Carbonates, with muscovite or quartz.

Quartz-dolerite
greenstones.

Quartz, carbonates, and chlorite; rarely albite or albite and quartz.

Vein-altered quartz-
dolerite green-
stones.

Any combination of quartz, carbonates, and muscovite; quartz, carbonates, and hematite; rarely albite and quartz.

Minerals in Altered Rocks

4. Those formed in altered rocks by an introduction of new chemical material, or occurring in fissure veins not entirely filled by segregation from the enclosing rock. The commonest mineral thus formed in rocks is pyrite; it is sometimes noted that pyrite occurs in the rock on each side of a quartz vein which carries no pyrite. In such cases the vein solutions have brought the sulphur which has fixed itself on the iron in the rocks. Chalcopyrite and arsenopyrite have also been noticed as replacement minerals in rocks. In some cases an introduction of magnetite seems probable. The gold and tellurides generally appear to occupy cracks in the rock, but these may be spaces of dissolution. They are frequently accompanied by roscoelite, which appears to replace sericite and requires an introduction of vanadium oxide. All the above minerals with the rarer sulphides are also found in fissure veins. Here also must be included those minerals produced by 'pneumatolytic action,' which imply the introduction of fluorine and boric vapors. Tourmaline is common in small quartz veins, and also as a replacement mineral in rocks. The minerals found with tourmaline in veins include quartz, carbonates, chlorite, albite, pyrite, chalcopyrite, blende, gold, and tellurides. When they pass through ultra-basaltic rocks tourmaline veins determine the formation of fuchsite, probably by the introduction of fluorine. Axinite has been found in one locality associated with quartz as a vein in the amphibolites.

Minerals Produced by Oxidation

5. Those produced by surface agencies (oxidation) from any of the former. Limonite is by far the commonest product of rock and vein oxidation, and under certain circumstances gives rise to horizontal nodular rocks termed laterites. Next to it comes calcite, which, whether by replacement or accretion, forms spheroidal or ellipsoidal pebbles known as cement pebbles, and also the calcareous cement to the superficial deposits. Mine workings in the oxidized zone show powdery red and yellow rock (colored by limonite) alternating with white material consisting largely of kaolin. These rocks are traversed by veins of quartz and limonite often containing secondary gold. In some cases the quartz itself may also belong to the same period of formation. Incrustations of psilomelane are common. In the oxidized portions of the telluride lodes secondary gold (mustard and paint gold), cerargyrite, massicot, emmonsites, asbolite, malachite, and gypsum have been recorded.

Mineral and Composition.	Color and Lustre.	Cleavage and Fracture.	Chemical Tests.	Notes.
Altaite—PbTe.	Lead gray with a yellowish tinge.	Perfect cubic cleavage.	B.B., easy fusibility; presence of Pb and Te, absence of S. Wet way, presence of Pb and Te.	Resembles galena.
Calaverite—AuTe ₂ .	Pale bronze yellow with bright metallic lustre.	No cleavage; subconchoidal fracture.	B.B., easy fusibility; presence of Te; bead of gold on roasting on charcoal; occasional recalescence.	Some resemblance to pyrite, but much less hard.
Coloradoite—HgTe.	Iron black color.	No cleavage; subconchoidal fracture.	B.B., easy fusibility; presence of Te; complete disappearance on roasting on charcoal; mirror of Hg in the closed tube. Wet way, presence of Hg and Te.	cf. petzite and fahlore only distinguished by chemical tests.
Hessite—Ag ₂ Te.	Lead gray to steel gray; tarnishes readily.	Cleavage indistinct; fracture somewhat conchoidal.	B.B., easy fusibility; presence of Te; Ag bead after heating on charcoal with carbonate of soda. Wet way, presence of Ag and Te.	cf. petzite when tarnished.
Krennerite—(AuAg)Te ₂ .	Silver white to brass yellow; brilliant metallic lustre.	Perfect basal cleavage.	B.B., cf. calaverite, but decrepitates violently. Wet way, presence of Ag and Te.	When massive indistinguishable from sylvanite unless the latter is twinned.
Petzite—3Ag ₂ TeAu ₂ Te.	Iron black color; metallic lustre.	No cleavage; subconchoidal fracture.	B.B., easy fusibility; presence of Te; white malleable bead on heating on charcoal with carbonate of soda; the bead becomes yellow on warming in HNO ₃ . Wet way, presence of Ag and Te.	cf. coloradoite and fahlore.
Sylvanite—AuAgTe ₂ .	Silver white; brilliant metallic lustre.	Perfect cleavage in one direction.	B.B., cf. calaverite. Wet way, presence of Ag and Te.	cf. krennerite; a twinning striation perpendicular to the cleavage sometimes observed.

Gold

Unlike its occurrence at Cripple Creek, free gold is common at Kalgoorlie in unoxidized telluride ores as well as in the oxidized. In the former it occurs as large or small lumps of irregular size embedded in the rock, or in quartz veins traversing it. Crystal forms have not been observed, although sometimes the gold is bounded by plane faces where it has rested on quartz crystals. It is generally found in

close association with the tellurides, and has probably, in many cases, been precipitated by them. At the Kalgurli mine it occurs in intimate association with a copper telluride, which it veins in a very intricate manner.

The Tellurides

As little information about the tellurides is accessible in the standard English textbooks on mineralogy, the composition, physical character, and the

modes of recognition of the different species found at Kalgoorlie will first be briefly outlined.

Composition

Calaverite corresponds nearly to the formula $AuTe_2$, but contains small amounts of silver, as shown in the preceding table of analyses made on Kalgoorlie specimens.

Sylvanite and Krennerite.—Both these minerals are silver-gold tellurides of the general formula $(AuAg)Te_2$, but while krennerite shows variable proportions between the silver and gold, sylvanite approximates closely to the formula $AuAgTe_4$.² Since both are silver-white minerals with a good cleavage, their separation, in the absence of crystal forms, as is the case at Kalgoorlie, is not practicable. As will be seen from the table of analyses, both minerals appear to be present. The first analysis referred to by Frenzel as sylvanite has been referred to as krennerite by Rickard³ and Hintze.⁴ The others approximate more nearly to $AuAgTe_4$.

Petzite

Petzite is a gold-silver telluride, the analyses of which approximate closely to the formula Ag_3AuTe_2 . Owing to its similarity to coloradoite it is difficult to obtain pure for analysis, as is evident from those quoted below.

Spencer⁵ considers it probable that in the above tellurides "the gold and silver do not isomorphously replace each other, as is usually considered to be the case, but that they are present in atomic proportions, as indicated in the formulae adopted above. These formulae may represent double tellurides or possibly simple salts (perhaps tellur-aurates, analogous to sulph-antimonites)."

Gold-Tellurium Alloys

On the other hand, Lehner in a recent paper⁶ has put forward the view that the gold-tellurium minerals are not chemical compounds at all, but alloys. His chief arguments are that the tellurides can precipitate gold from solution in the same manner as metallic tellurium of gold-tellurium alloys, and that it has proved impossible to prepare the minerals synthetically.

Against Lehner's view, it may be pointed out that three of the above minerals, calaverite, sylvanite, and krennerite, possess definite crystalline form, a property not possessed by alloys. Although in the case of calaverite the crystalline form is peculiar, and has led Smith and Prior to believe that the crystals are really not homogeneous, sylvanite and krennerite have a perfect cleavage, proving a regular homogeneous molecular structure. At Kalgoorlie both calaverite and petzite are found in massive forms that might well be alloys from their physical appearance, but this is also true of coloradoite. Lehner restricts his alloy hypothesis to the gold-tellurium minerals.

The apparent lack of definite molecular proportions is probably due, as Spencer has pointed out, to the difficulty of obtaining pure material for analysis. Still the analyses show that the minerals approximate more closely to definite chemical compounds than would be expected in the case of alloys. Moreover, the close association of several species in the same ore is difficult to understand if they are formed as alloys. It is, however, conceivable that calaverite, petzite, and coloradoite have been formed as definite chemical compounds and have since degenerated into alloys, which, in the case of crystalline calaverite, have formed pseudomorphs after the original crystals.

Kalgoorlie Minerals

Goldschmidtite, kalgoorlite, and coolgardite are names that have from time to time been applied to Kalgoorlie minerals. Goldschmidtite, first described from Colorado, has since been shown to be identical with sylvanite. Kalgoorlite (Pittman⁷) and coolgardite (Carnot⁸), two species found in Kalgoorlie specimens have been shown by Spencer⁹ in an exhaustive discussion to be capable of explanation as

- ⁵Spencer, *tom. cit.*, p. 274.

- ⁹Spencer, *loc. cit.*

mixtures of the above tellurides and coloradoite. As neither Pittman nor Carnot make any mention of coloradoite, which assumes a prominent place among Kalgoorlie tellurides, Spencer's contention possesses considerable weight. In the following table of analyses are also given two (No. 6 and 7) which have been calculated by Spencer as mixtures of petzite and calaverite.

Hessite

Hessite is generally ascribed to the formula Ag₂Te, but most analyses show a decided proportion of gold. No analysis has been made of the mineral from Kalgoorlie. It may be pointed out, however, that apparently homogeneous pieces of hessite are shown when polished and treated with acids to be composed of a mixture of hessite and petzite. An analysis made without this knowledge would certainly show a considerable percentage of gold. It is to be noted that among the analyses quoted by Dana those made on crystals of hessite contain but little gold. It is most probable, therefore, that hessite is a pure silver telluride without gold.

Coloradoite was described by Genth from Colorado as HgTe, but Simpson,¹⁰ from an analysis of the Kalgoorlie mineral, suggested Hg₂Te₃. Speneer made a new analysis¹¹ on carefully selected material, with the result that Genth's formula (HgTe) was confirmed. The analyses were as follows:

	1.	2.	3.

Melonite. A hitherto unrecorded telluride of nickel has been found at the Hidden Secret mine. It agrees in physical characters with the melonite as described in Dana's 'System of Mineralogy,' and gives all the usual blowpipe tests for nickel and tellurium. The following characters were noticed:

Sulphuric acid test for tellurium, very good.
Heated before the blowpipe on charcoal; does not fuse readily; colors the reducing flame blue-green; gives a white sublimate of TeO₂ and the characteristic tellurium odor; after long heating fuses with spluttering; the yellowish green or brown residue colors the borax bead a reddish brown color when very little of it is introduced.
In the closed tube does not fuse; indistinct sublimate of TeO₂.
Dissolves in nitric acid to a colorless liquid, which becomes green with one drop of hydrochloric acid.

Torrington Blatchford, of Kalgoorlie, kindly made a qualitative examination, which showed the absence of silver, lead, copper, and bismuth, and abundance of nickel and a slight trace of zinc. As very little material was available, a quantitative analysis was left for one more expert in telluride analysis.

Rickardite

Rickardite (?). Rickardite, the tellurium of copper (Cu₂Fe₃) has been recorded only from the Hope mine, Vulean, Colorado, by Ford.¹² M. Brimsden, metallurgist of the Kalgurli mine, called our attention to a telluride in that mine containing copper and gold. Etching experiments showed that the mineral is intricately veined by free gold, so that it is probably a pure copper telluride. The mineral varies somewhat in appearance according to the abundance and fineness of distribution of the free gold, which is seldom visible before treatment in acid. Two varieties were noticed, the one with very fine fracture and a black metallic appearance; it proved to have leaf-like films of gold often between the cleavage planes; the other was coarser and of a grayish metallic appearance, with a distinct cleavage; the included gold was not too finely distributed. The mineral is quickly attacked by cold nitric acid which renders the free gold visible.

A small fragment, as free as possible from included gold, fused easily before the blowpipe on charcoal, colored the flame blue-green, and gave a dense white sublimate of TeO₂; the bead obtained, which was small in proportion to the original fragment, was of a brownish color when cold, and was malleable. On treatment with hot acid it effervesced and became golden. The solution obtained by decomposition in nitric acid was of a greenish color, which turned to blue on neutralization by ammonia. The sulphuric acid test for tellurium was obtained more easily than in the case of any other telluride. It was further observed that the mineral was decomposed by long heating with ammonia with the production of a blue solution.

The above tests leave little doubt that the mineral is a telluride of copper. It differs considerably in color from that recorded for Rickardite. It was noticed, however, that occasionally on tarnished surfaces the colors were similar to those of bornite.

¹²Ford, W. E., *Am. Jour. Sci.*, XV, 1903, p. 69.

A quantitative analysis was made in the laboratory of the Kalgurli Gold Mines.

Diagnostics

The presence of tellurium may be easily detected by blowpipe tests. When heated on charcoal, in the oxidizing flame all the gold and silver, lead and mercury tellurides quickly fuse and emit dense white fumes, which have a characteristic odor. They coat the charcoal with a volatile white sublimate of TeO_2 . When the bead is touched with the reducing flame it imparts to it a bright bluish green color. When heated in the closed tube, they again fuse and form a white sublimate of TeO_2 near the test. This fuses on further heating to a liquid, which is yellow when hot and white when cold. Occasionally also a black sublimate of metallic tellurium is obtained, especially with calaverite, but also with coloradoite when large fragments are used. An easily performed wet test consists in heating a fragment of the mineral on a porcelain plate, and allowing a few drops of sulphuric acid to flow over it. Under certain conditions of temperature a flash of purple color is obtained, owing to the formation of tellurates. This test may also be applied to the sublimate of tellurium in the closed tube, or to the coat of TeO_2 on charcoal.

Determination of the Tellurides

The distinction of the different tellurides can easily be made by a combination of physical characters and blowpipe tests. Calaverite and sylvanite give a malleable yellow bead when simply roasted on charcoal, but may easily be distinguished by color and cleavage. Petzite gives a silvery, malleable bead only when heated with soda on charcoal, and this bead becomes golden on parting with nitric acid. Coloradoite, which greatly resembles petzite in physical appearance, disappears completely when heated on charcoal, and gives a mirror of globules of mercury when heated in the closed tube. Hessite resembles petzite in giving a brittle bead, but is much harder to reduce with soda and charcoal. If a large piece is used, dendritic growths of silver form on the surface of the bead. Altaite may be distinguished from the others by its cubic cleavage and greater flexibility. While lead may be detected by blowpipe methods, it is more satisfactory to have recourse to wet tests. From galena it may be distinguished by the sulphuric acid test for tellurium.

Melonite is distinguished from the others occurring at Kalgoorlie by the combination of perfect cleavage and yellow-brown color. It does not fuse readily before the blowpipe or in the closed tube, but forms a greenish yellow mass on roasting. A minute amount of this imparts the characteristic brownish red colors to beads of borax and microcosmic salts. The copper telluride found at the Kalgurli mine is distinguished by the combination of cleavage and gray-black color. Owing to the presence of veinlets of gold penetrating it, some difficulties are met in blowpipe analyses. Thus, when roasted it gives at once a yellow bead. It is very easily soluble in cold nitric acid to a greenish solution, which turns blue with addition of ammonia, while the free gold does not pass into solution. It

is noteworthy that ammonia itself turns blue after prolonged heating with the natural mineral.

Metallography of the Tellurides

A few experiments, with a limited amount of material and the rudest of apparatus, were made on the behavior of tellurides when polished and etched. The results were sufficiently encouraging to show that much information as to the constitution and interrelation of the minerals may be gained by more extended work in this direction. Because of the difficulty to the ordinary man of obtaining material suitable for handling, it could be done most easily by the mine chemists.

Owing to the softness of the tellurides, it is difficult, in thin sections of rocks containing them, to obtain a smooth surface; calaverite, in particular, shows a coarse hackly surface, which alone, without the paler color, would distinguish it from pyrite; sylvanite, petzite, and coloradoite give much smoother surfaces, but generally rougher than magnetite, which the last two resemble in color.

If larger pieces of the tellurides alone are taken, it is possible to grind a smooth metallic surface. The abrasives used were, first fine emery on a wheel, then flour emery on glass, and the final surface was obtained by 'dynamite cloth,' although wash-leather is preferable. The chief difficulty is to remove the larger scratches made by the fine emery.

On the polished surface it is sometimes possible to recognize the presence of more than one kind of telluride, or the inclusion of extraneous minerals, such as gold and chalcopyrite. In the case of the copper telluride the cleavage was visible, but not in the case of sylvanite or melonite.

Solvent for Tellurides

The most suitable solvent employed was nitric acid. In the case of the copper telluride, a few seconds' immersion in cold nitric sufficed to bring into relief the veining by gold and the cleavage of the mineral. In other cases the mineral was heated for a few minutes with the acid. It was noticed that the greater amount of silver compared to gold in the mineral the quicker the decomposition. In this manner the presence of petzite in the Hidden Secret hessite was demonstrated. Etching with nitric acid brought to light no trace of crystalline structure, except in the case of sylvanite, in which a polysynthetic twinning, invisible on the cleavage planes, was brought to light. The presence of this twinning serves to distinguish sylvanite from krennerite. On one occasion a slight indication of cleavage was suspected in hessite, but was destroyed by further boiling in nitric acid. No success met attempts to bring out the cleavage of sylvanite.

Considerable difficulty was experienced owing to the deposition of chloride of silver on washing in the Kalgoorlie 'scheme' water. On allowing the specimen to dry, the surface became blackened. This and the tarnish produced by nitric acid can be removed to some extent by washing in solutions of potassium cyanide.

With *aqua regia*, on the other hand, the order of solubility changed. The greater the amount of silver in the telluride the slower was the decomposition.

tion, owing to the deposition of silver chloride. In this way petzite became dissolved away below the surface of the preparation, while the hessite enclosing it was little attacked. The 'solution surface' of the petzite presents curiously curved shapes, and seems to indicate a lack of crystal structure. Sulphuric acid failed to give any satisfactory results as a solvent. Time did not permit further experiments. A large number of solvents might be suggested, including KMnO_4 , $\text{K}_2\text{Cr}_2\text{O}_7$, FeCl_4 , sulphur monochloride, etc., all of which are known to be-
compose tellurides.¹³

The results obtained may be briefly summarized:

Calaverite.—Surface slowly lowered and tarnished by HNO_3 ; more rapidly lowered by *aqua regia*.

Sylvanite.—A polysynthetic twinning revealed by HNO_3 ; iridescent colors obtained by *aqua regia*, followed by cyanide solution.

Petzite.—Surface slowly lowered by HNO_3 ; if subsequently polished on wash leather, becomes golden colored; an undulating solution-surface produced by *aqua regia*.

Hessite.—Surface lowered by HNO_3 , apparently quite regularly; a slight indication of a cleavage or parting obtained; deposit of silver chloride by *aqua regia*.

Coloradoite.—Surface lowered by HNO_3 , not so quickly by *aqua regia*.

¹³Lehner, *tom cit.*

Copper telluride.—Surface quickly lowered by HNO_3 ; cleavage becomes marked.

Occurrence

The tellurides are for the most part confined to the richer shoots in the large lodes in the 'Mile.' Outside of this, they have been found in most abundance in the Block 45 and Eclipse leases of the Oroya Links and the Hidden Secret gold mines. From a mineralogical point of view, the shoot now worked at the 400-ft. level of the Kalgurli G. M. and the Hidden Secret shoot are the most interesting. The Kalgurli shoot is very rich in sylvanite and contains also calaverite, petzite, coloradoite, and the hitherto unrecorded silver and copper tellurides, and also fahlore, cerargyrite, bornite, and oxidized materials difficult to separate from the tellurides and sulphides, but suspected to be cuprite, emmonsite, and montanite (the last as a coating on coloradoite). The Hidden Secret telluride is mostly a black color, proving on etching to consist of mostly hessite with subordinate petzite, while altaite and melonite are also present. The non-telluride minerals are chiefly chalcopyrite, pyrite, and bornite, while large masses of cerargyrite were obtained from the oxidized zone. The following table, amplified from Spencer, gives the list of species so far identified from the chief mines of the field. It will be noticed that sylvanite is commoner on the eastern than the western side of the 'Mile.'

Sulphur as a Fertilizer

In connection with the wide outcry made over the effect of sulphur fumes upon vegetation, it is interesting to note that sulphur itself is well known to have marked value as a fertilizer. B. Heinze, in Germany, has recently called attention to this, his experiments showing the beneficial action, which is not well understood. A. Demolin, in France, concludes that the sulphur is converted to SO_4 by micro-organisms and that its fertilizing action is partly due to its action on micro-organisms and partly to the formation of H_2SO_4 , which by its action on lime

salts and other bases makes mineral matter more readily available to the plants. V. V. Sabashnikov, of the Russian Agricultural Experiment Station Service, has found that an application of 10 gm. of sulphur per square metre to a fertile clay soil greatly increased the yield of barley and rye. E. Lierke, in Germany, finds that fertilizers containing sulphur compounds gave better results with fruits than other fertilizers.

Coke production in Illinois in 1912 amounted to 1,764,944 short tons, valued at \$8,069,903, against 1,610,212 tons in 1911.

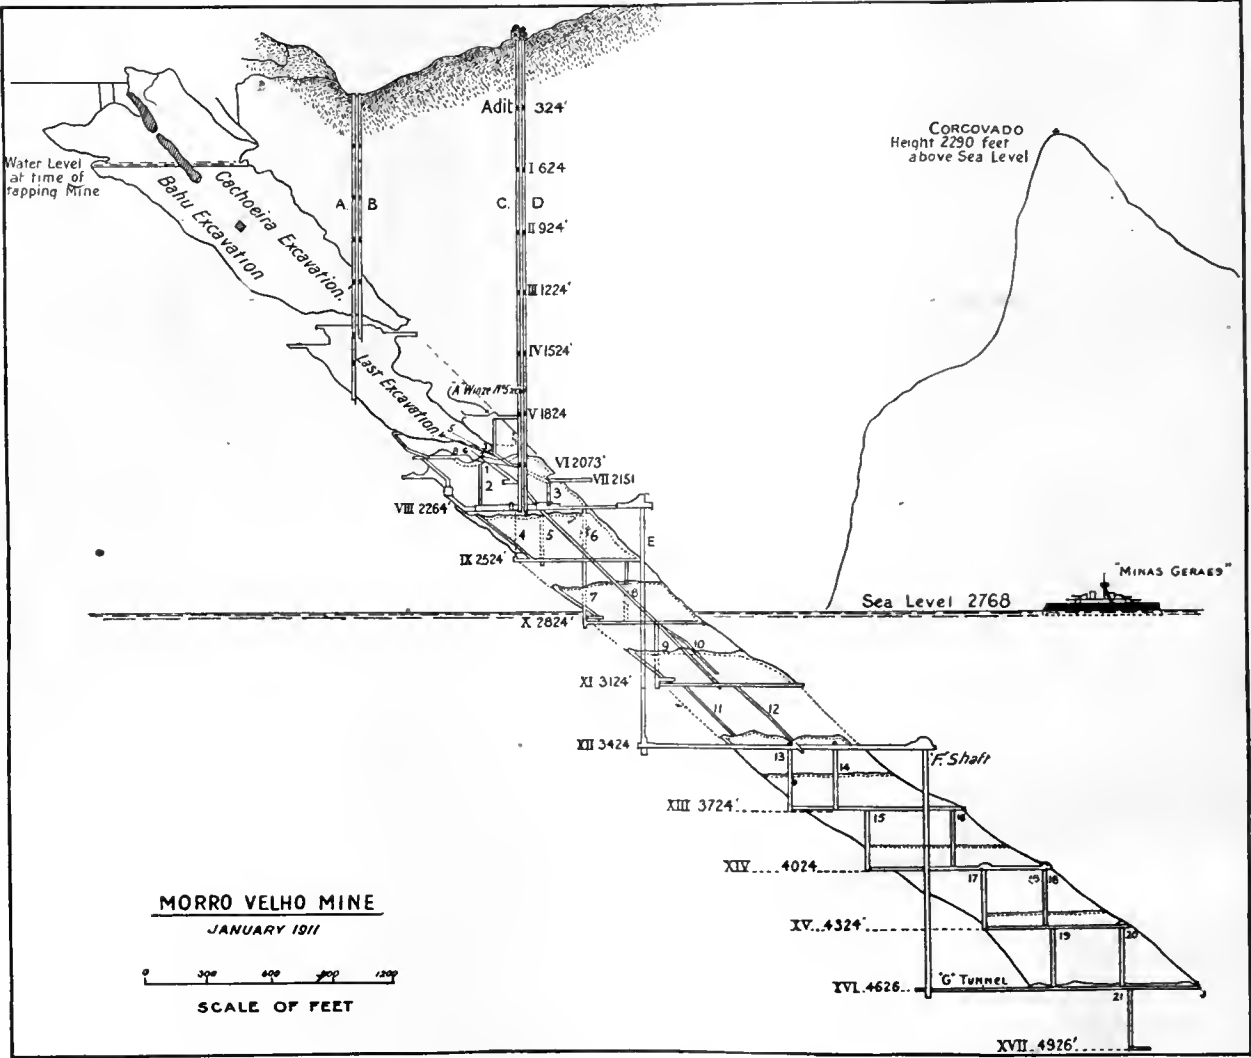

Temperatures at the Morro Velho

The Morro Velho, the famous Brazilian gold mine owned by the St. John Del Rey Mining Co., which has now reached a depth of 4926 feet, affords opportunities for measuring rock temperatures that are unusual. Incidentally, these temperatures make the problem of ventilation severe. In his recent annual report, George Chalmers, the superintendent, discusses the matter in part as follows:

The Sirocco fan plant, installed in February 1912, has run satisfactorily during the year, with the exception of the interruption attributed to a number of small stoppages, amounting in all to 13 hours 40 minutes, caused by the generating plants supplying

rock and levels or excavations, it will be found that the rock temperature as represented by readings taken at the extremity of 10-ft. holes in the rock, shortly after the particular locality had been opened, decreases, and continues to do so for a considerable time after being exposed to the air from surface, and consequently it is probable that even the first reading is a little below the temperature of the rock previous to the excavation being made in it. No doubt longer holes would give readings approaching more closely the true rock temperature, but the thermometer at the extremity of a 10-ft. hole probably gives readings sufficiently close for practical purposes.

It has been previously pointed out that horizon

the power being temporarily shut down by thunderstorms, and not due to any trouble in the fan-house.

Power Consumption

The average power put into the fan has been below the full capacity of the 150-hp. motor, but sufficient to pass through the mine about 72,000 cu. ft. of air per minute, which after being split up among the several parts of the mine, has kept the workings at a temperature, although hot, not sufficiently so to interfere with the efficiency of the men. As a proof of this it may be said that there are many contractors and others working in the mine who would not be satisfied to remain there if they could not work 50% overtime, or a total of 12 hours. By referring to back reports on the temperatures of the

14 (4024 ft.) at the time of being opened, showed a rock temperature of 98°, and at horizon 17 (4626 ft.) it was 105°. A line passing through these two points and projected to horizon 22 (6120 ft.) indicates a temperature of 117°, and at horizon 18 (4926 ft.) one of 107½°, but the actual temperature registered from the bottom of a 10-ft. hole, bored as soon as possible after the shaft reached that point, showed 11½° less. This can be accounted for by the cold air from machine-drills working close at hand, together with the cooling effect by the large volume of air coming into the bottom of the shaft from the 12-hp. auxiliary fan. As a proof of what has been stated above as regards the fall in rock temperature when exposed to air from surface for some time, it will be seen that at horizon 17 the rock temperature at the

time of the first reading shortly after the rock was opened, was 105°, that during the hot months from November to March it had fallen a degree, that for 1911-12 for the same months it fell to 100½, and for 1912-13 it was only 98°, or a total fall of 7°, and at the horizons above, the fall has continued with marked regularity. At horizon 16 and those above, the air temperature is not quite so regular, but represents a considerable average fall since 1910-11.

Changes in Temperature

There is, however, little change for the past year as compared to that of the year previous, probably owing to the fact that during the past year there has been no increase in the volume of air, while the mine has been deepened, and a considerable area of heating surface has been added by the rock opened in development. Had the fan been worked to the full power of the 150-hp. motor, which it must be remembered is only half what it is finally to work under, no doubt the temperature of the air for the past year would have more closely approached the average temperature of places opened for some time, and what may possibly be expected after the horizons have been connected with the main ventilating system, and with an ample supply of air. It must be remembered that the above readings have been taken during the four hottest months, when the surface temperature is considerably greater. During the remaining eight months the average surface temperature would be lower, and the readings within the mine would be less to some extent. In sinking and driving in new rock dependent on auxiliary ventilation, the temperatures are higher; for instance, at the bottom of the 'G' shaft, at horizon 18, during sinking operations the rock temperature was 106°F., and the air temperature 98°. The men working there did not appear to feel the heat very much, and in the drift from the present bottom of the shaft, where probably the temperature is slightly higher, the drillers are penetrating the rock at about a yard per day, which is a good average for tunneling in this rock close to surface. The fact of the mine being a dry one is probably a matter of considerable importance, the wet bulb showing a temperature considerably below the dry. It has been stated by writers on the subject that a temperature of 100°F. with the air so dry that the wet bulb temperature is only 80°F., is no worse for the efficiency of the men than a saturated atmosphere of 80°. I also find it recorded that the Yellow Jacket rock on the Comstock, at the 2840-ft. level shows a temperature of 154°, while the air in the adits is 110°, yet good English, American, and Canadian labor is available at reasonable prices. It may be mentioned that the native working in the open here with the sun over his head, has to bear a temperature of 107° and upward, and not unfrequently in our shops, with open sides, the temperature in the day is over 100°.

Minimum Temperature

It is evident that everything possible should be done to reduce the temperature to a minimum, both from a humane as well as business point of view, and the only effective way to accomplish this is by paying special attention to the airways, keeping the

mainway into depth below or ahead of the explorations beneath the stopes, and by reserving ample power for the fans. By attending to these points the maximum quantity of air can be passed through the workings, but the air must enter the mine as cool and dry as possible. Experiments on cooling the intake air by suitable arrangements in which power water is being used, without interfering with the power, are being tried; also some experiments in insulation have given results of interest.

Metallurgy in Rhodesia

The following notes were recently published in the *Kalgoorlie Miner*, Western Australia, after an interview with H. T. Brett, who was a metallurgist at Kalgoorlie several years ago, but has since been in Rhodesia with the Consolidated Gold Fields of South Africa.

There was recently erected at the Shamva mine a mill of 56 stamps, using ¼-mesh screens and having a capacity of 1800 tons per day. On the Faleon there are 24 Nissen stamps, with a capacity of 500 to 600 tons per day, and it is expected that a flotation process will also be installed. At the gold and copper mine it is also proposed to erect 24 Nissen stamps. The Globe & Phoenix, considered to be one of the richest mines in the world, has developed 180,000 tons of ore, worth \$33.60 per ton, notwithstanding that the mill has been crushing similar ore for the past two years. Among the mines which will start crushing during the next twelve months are the Shamva. This is a big low-grade property, situated on a hill, the ore from which is worth \$4.80 per ton. This, it is estimated, will be mined and treated at a cost of \$2 per ton. A plant is being erected to deal with 50,000 tons per month. From this property 2,000,000 tons can be worked by open cut. The development of this mine to date has not cost much above 12c. per ton. The Faleon, a copper and gold property, with ore containing 3% copper, and \$5 gold per ton, will also begin crushing shortly. There has been developed in this mine about 600,000 tons of ore, and the plant will contain Nissen stamps, a Minerals Separation plant, blast-furnace, and convertors. Then there is the Cam & Motor, which will be equipped with a large plant on Western Australian lines—dry crushing, roasting, involving cyaniding, and capable of treating 500 tons per day. In this mine there is developed 1,000,000 tons of ore, worth about \$10.80 per ton.

Flotation at Broken Hill

The following are outputs of the Zinc Corporation and Amalgamated Zinc company's plants during May:

	*Zinc Corporation.	Amalgamated Zinc.
Tailing treated, tons.....	27,670	46,960
Zinc concentrate, tons	7,605	12,603
Lead concentrate, tons	4,154	137
Total income.....	\$244,000	\$173,000
Working profit	68,000	86,000

*This Company also treated 15,554 tons of ore from its South Blocks mine.

Manufacture of Eucalyptus Oil

*The use of this oil was until recently restricted to medicinal purposes, but now that the Minerals Separation process of flotation of sulphides from ores finds a use for it, the manufacture has attained quite an important place.

A recent visit to one of the stills belonging to the Eucalyptus Oils, Ltd., which Company is operating in the Braidwood district, New South Wales, afforded an opportunity of inspecting the methods employed in producing the oil, and supplied a cheerful example of another source of wealth to Australia, which, with the extension of the patent process (since its complete success has been proved here) to other mining countries, will, doubtless, also mean in the future a valuable export trade.

There are over 200 varieties of eucalyptus now classified, and it is the peppermint class which meets the requirements of oil production. Their oils contain a large percentage of *phellandrene*, which, while being detrimental to their use for medicinal purposes, increases their suitability for flotation purposes, and they are large producers, giving in the case of *Eucalyptus amygdalina* up to 40 lb. of oil per 1000 lb. of leaves, and can thus be produced sufficiently cheaply to be profitably employed.

The first step taken is to fell the trees selected, and as the foliage only is required, all of them having a fairly good leaf growth, from saplings to those of about 18 in. diam., receive the attention of the ax. The large branches are then cut off, and these, in turn, cut up with a knife to branchlets not exceeding 16 in. long. The wood is useless, consequently as little of it is left as possible, having due regard to the time taken in the trimming. These branchlets are piled by the fallen tree, and later collected by bullock or horse drays, which traverse the bush on rough tracks cut for the purpose. Thence they are conveyed to the still, which is usually situated on the side of a running creek. The form of still mostly used is made from 400-gal. square tanks, with the tops cut out and steam-proof lids substituted; these are used singly, coupled, or in three, as the output may demand.

Holes for fire are dug under them, and pipes carried from the sides through the running water and emptying their mixture of distilled oil and water into a suitably placed receiver, complete the plant, and the oil is subsequently skimmed from the top of this receiver, much in the same manner as cream is skimmed from milk. A wooden platform is usually employed at the bottom of the tank, leaving several inches under it in which to boil the water, and the tank having been filled with the leaves and tightly pressed down, the lid is screwed on, the fire lighted, and nothing remains but to attend to the stoking for a period ranging from 4 to 6 hours, by which time practically all the oil contained in the leaves has been carried off into the receivers. It is not claimed that this form of plant is an ideal one, and better results can be obtained by the use of an improved class of still; but the cruder form has many advantages, including that of being

rapidly constructed, easily moved from place to place as circumstances may require, and of being so simple in construction as to need little or no expert attention. The oil, when taken from the receiver, having been tested and classified, is packed in drums and is then ready for use. In the case of the medicinal oils, it has further processes of re-distillation to undergo in separating its various constituents for the uses to which they are applied, but as it is only in regard to the oils used for mineral separation that these enquiries were made, they do not come within the scope of this article.

The Irvinebank Aerial Tramway

*The Irvinebank Mining Co., Ltd., North Queensland, has recently completed the erection of an aerial ropeway connecting the Governor Norman mine with the stamp-mill storage-bins and is effecting a large saving in the cost of transit of ore between those points, and is otherwise giving every satisfaction. The length of the tramway is nearly 1½ miles. It crosses the Ibis gorge, and its greatest span is 1300 ft., the buckets being about 300 ft. above the stream. It is built on the single-rope system; that is, a single traveling rope which both supports and pulls the load along. This system, which has been brought up to its present state of perfection by J. Pearce Roe, director of Ropeways, Limited, of London, is remarkable for simplicity of working, construction, and low cost. The ropes are supported on 15 trestles of an average height of 21 ft., built of light steel sections securely braced by tension rods. On the ropes there are 45 buckets, each hung from patent carriers and capable of holding about 500 lb. of ore. The buckets are despatched from the loading station at the rate of one per minute. A patent bell-timing apparatus, mounted at the loading station, regulates the spacing. The stations, or terminals, are of simple design, and only one man is required at each terminal. As soon as a bucket arrives at the loading station, it automatically releases itself from the rope, and, running on to a shunt rail, is carried under the ore-bins, where it is filled from chutes specially constructed to facilitate the loading. The carrier is then run round to the take-off point, where it again automatically attaches itself to the rope, and so travels on to the unloading station, where a similar action takes place. The bucket is here received by the man in attendance, who, by simply knocking up a catch on the bucket, tips the ore into the receiving bins.

The ropeway is driven by a 10-hp. engine. The power necessary, however, to keep the machine running after it is under way is approximately 4 hp. The total cost of the entire plant, including bins at the mine, engine, etc., was under \$17,000, and it has reduced the cost of conveyance of ore from \$1.44 to about 12c. per ton of ore carried.

Gold is reported to have been discovered in large quantities in the southern part of the Province of Katanga, in the Belgian Congo.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Rand Conditions and Future Outlook

The Editor:

Sir—Owen Letcher, by virtue of a long residence on the Rand, coupled with unique facilities for getting detailed information in regard to the mining industry, is a writer who must be taken seriously on such a subject as that selected by him in your issue of June 28, 1913.

It would be impossible, however, for any writer to take up the controversial points that must enter into the consideration of such a subject, without laying himself open to criticism on some point or other, and, as a matter of fact, I find that there are several questions upon which I feel that issue may be taken with Mr. Letcher.

The burden of Mr. Letcher's article is that the Rand, as a gold producer and profit earner, has just about reached its zenith, and that, in the near future, the beginning of a gradual and general decline must be looked for. On this broad platform I am entirely in agreement with Mr. Letcher, and I consider that his presentation of the case in support of this contention is extremely lucid and convincing.

Influence of Depth on Grade of Ore

It is on some of the internal questions touched upon by Mr. Letcher that I would wish to remark. For instance, he says: "I do not see any real evidence to support the statement that poorer ore is the rule as greater depths are reached on the Witwatersrand." He continues: "This is, of course, based on experience to date when a maximum depth of 5000 ft. has been reached, but I do think that many of the Witwatersrand mines have milled ore having a higher value than the average value throughout this region" (the central mile).

I must confess that I cannot follow Mr. Letcher in this statement. It is some years since I left the Rand, but certainly up to that time the available evidence in my possession was in support of the argument that there is diminution of grade as depth is attained. This expression "as depth is attained" in itself, however, requires some explanation, for it must not be understood that it is intended to mean that the first hundred feet must necessarily be richer than the eighth hundred feet. There are many cases, of course, where this was so, but this is not the argument. It is in dealing with the main reef series as a whole, and dividing the area on the dip of the series into three parallel zones of 2000 ft. each in width, the first zone extending say from the outcrop to 2000 ft., the second from 2000 to 4000 ft., and the third from 4000 to 6000 ft., that I would prefer to take as my basis, explaining at the same time that this classification is more or less arbitrary, and to be only taken as a generalization. Would Mr. Letcher then tell me

that the average grade of the ore disclosed in the known developed mines, as arrived at by a 5-ft. sectional sampling throughout, shows no falling off as between these three zones? I do not wish to take the case of particular mines, as I have no desire to express an opinion which might be judged as prejudiced, or damaging to any one part, but here there is presented a question that, from the engineering and scientific standpoint, is of great interest, and I believe, and it is my firm and unhesitating opinion, that a comparison such as that suggested by me would show that there is undoubtedly, on average, a material falling off as between the second and first zones, and again, but in lesser degree, as between the third and second zones. This same question was taken up by Mr. Schmidt in an article presented by him to the Institution of Mining and Metallurgy in 1911, and at that time there was some discussion on this particular point, and, in my judgment, the general trend of opinion then was opposed to that now expressed by Mr. Letcher.

I cannot see what useful purpose it serves to make a claim, such as that put forward by Mr. Letcher, which, according to my observations and experiences on the Rand, is quite inaccurate, especially as it appears to me that the figures submitted by him, reflecting the operations over the past five years, are in direct conflict with that view.

Mr. Letcher's next point is contained in the following: "Admittedly, there is much to be said in favor of selective mining—in other words, making hay while the sun shines. Unfortunately, however, that such a policy has been pursued is not generally recognized. Unfortunately, also, the expectations of lower working costs have not been realized. On the face of official statistics, given herewith, the winning of an equal dividend from ore of lesser grade as a consequence of lower running charges has been a presumption that has not been fulfilled. Neither has the automatic transfer of ore from the unpayable or unprofitable side of the ledger to the payable or profitable side been manifested, and this despite the operation of 858 additional stamps and 173 additional tube-mills."

Selective Mining

Selective mining is a complicated question, and, unless its application is expressed in figures, it is difficult to follow any argument closely. All mining is more or less selective, within limits, and it is only a question of the degree that really calls for criticism. Mr. Letcher's idea, of course, is quite clear. He is referring to the policy, advocated by certain engineers, of attacking, whenever and wherever possible, the richer parts of any mine, regardless almost of everything. The argument made in favor of this policy is that the ultimate profit made is greater because of the compound interest factor.

Take, for instance, a mine in which the ore developed amounts to a total of 100,000 tons blocked out, giving an average recovery value throughout of, say, 7 dwt., divided as follows: 5000 tons at 40 dwt. equals 200,000 dwt.; 75,000 tons at 6 dwt. equals 450,000 dwt.; 20,000 tons at 2.5 dwt. equals

50,000 dwt.; total, 700,000 dwt.; and assume further that this 5% of 2-oz. rock (recovery value) is distributed in small blocks at various points in the mine; also that the cost of development on the full tonnage of 100,000 tons has amounted to 2s. 6d. per ton. The advocates of selective mining would then proceed to deal only, in the first place, with 5000 tons of 2-oz. rock.

If this could be done, maintaining an average working cost, such as could be realized in taking merely average-grade ore and working on some scheme of concentration in the mine, then there would undoubtedly be a great deal to say in favor of it from a present-value standpoint.

Selective Mining v. Working Cost

But what would happen? In order to mine only this grade of ore, work would have to be conducted on every level in the mine. Tramming, shoveling, skip-filling, lighting, air-lines, rails, etc., would all have to be maintained at each of these points, from which only very small quantities of ore would be taken. The supervision would have to be out of all proportion to the tonnage, seeing that the points of attack would be so far apart, and from every conceivable working condition aspect, the result of such policy must be reflected in abnormal cost. It is in this that the danger of the policy lies, as the only offset to this inflated expenditure is the interest obtainable on the larger amount realized per ton of ore handled. It is too complicated a matter to deal with in figures in an article of this kind, but I have made many calculations on hypothetical cases, and it is not difficult to postulate a case where persistence in such a policy might rob a mine of 50% of its potential profit. Contrariwise, however, it can be shown that the opposite policy of including worthless rock with the higher-grade ore may be followed to equally disastrous limits.

In fact, the whole problem of the limitations of selective mining rests in the factors of grade of ore *vis a vis* concomitant operating expenses, it being axiomatic that the more selective the mining the higher the working cost. In almost every form of mining, however, a certain amount of selection must be followed. It is in determining correctly the economic limit of the application of the principle that the capabilities of the administration will be shown. It is quite certain that there are mines where a straightforward policy, practically devoid of all selection, will show the best economic result, while there are others that could only be made to yield profits by sticking closely to that policy. It is absurd to generalize, and until a specific case is taken, it is quite impossible to have any view one way or the other.

Steadiness of Output

But ultimate profit is not the only objective—there are other weighty considerations. Steadiness of output, for instance, is desirable in mining, and the only way to arrive at anything stable in this direction is by creating reserves of the higher grade of ore. All mines vary in some degree in the distribution of their mineral value, and, in conse-

quence, all mines will have their phases of lower and higher grade ore periods of development. If a mine has two or three years ore-supply developed ahead of its mill, it is not difficult to regulate, within fair limits, the average output, seeing that the grade can be modified from time to time, as dictated by the results of current development. That is to say, if new development continues to show a better grade than the average of the existing ore reserves, then an increase in the grade milled might be allowed; whereas, on the contrary, if new development continues to show poorer average results, the grade of the current ore being milled might be correspondingly reduced. In this way a steady level of returns can be maintained and shareholders and directors can look forward with considerable certainty to the immediate future, and two or three years beyond that.

Influence on Returns

On the other hand, if a policy of selective mining is to be followed, where the richest ore is always to be taken out as soon as discovered, and sent to the mill, regardless of everything, there must be undoubtedly violent fluctuations in the returns, and considerable uncertainty as to the value of the Company's shares and its future. Furthermore, as already stated, operations under such conditions cannot possibly be carried on as economically as in the other case, and it is not at all improbable that the advantage and interest obtained by getting the returns from the higher-grade ore early into the bank, under this system, would, in many cases, be more than offset by the corresponding increase in the operating costs entailed. It should not be impossible, at a given time, to figure what the most profitable limit of selection should be, but I would say in general that if the principle is adopted, merely with the idea of rushing those points where the best ore appears, regardless of other factors, it must prove to be economically unsound, as there are undoubtedly many occasions when the working of lower-grade ores simultaneously with some of the higher-grade ores will yield a joint aggregate profit that could never be arrived at by selecting first the higher-grade ore and finally going back to the lower.

Effect of Increased Tonnage

This is one side of the question. Mr. Letcher has pointed out another feature, namely, that the increase of the number of stamps and the addition of tube-mills has not resulted in increased profits.

The object of adding this additional plant was originally to permit of the handling of much larger quantities of ore, with the idea that the general reduction of operating cost to be brought about in handling such larger quantities would result in showing a profit on a grade of ore that could not be made to yield a profit when only a small tonnage was being handled. Up to a certain point, this idea was undoubtedly sound, but here, just as in selective mining, the principle can easily be carried too far. Whether 100 tons or 1000 tons of ore are being broken per day, the hardness of the ore is not affected, and it still takes so much dynamite

and so much labor and so much other material to win one ton of rock from the mine. The main saving—and within certain limits a most important one—is in general administration charges, and other main charges, such as power, etc., but unless there are other factors of advantage automatically brought into play in the actual work to be done, the benefits possible are somewhat restricted.

If it be assumed that on the higher-grade ore, when handling a small tonnage, a stoping width of 24 in. has to be maintained, while in the other case a stoping width of 12 ft. could be carried, and assuming further that there was still a definite margin of profit to be made on the 12-ft. width, then there would unquestionably be a serious problem facing the administrator who had been instructed to follow the selective mining principle; and in fact, given that the margin of profit in the case of the 12-ft. stope were appreciable, a case might easily be postulated where the following of the selective mining principle would become merely absurd.

Increased Equipment

The real truth of the matter is, that in some cases additional stamps and tube-mills have been provided in mines whose more recent developments have not come up to the average of the earlier developments, and in some cases the falling off has been so considerable that it has been found impossible to keep even the same number of stamps running as the mine originally had on a much lower grade of ore. In other cases, it was found that the mine was in such a condition that it was quite impossible to do both the necessary amount of mining and development to feed the larger number of stamps even after incurring heavy expenditure on new shafts, ore-bins, and works of that sort, and undoubtedly mistakes were made in many cases for lack of a proper understanding of these internal considerations.

Turning again to Mr. Letcher's paper, I find that his charts are instructive. It will be noticed that the gross production from 1908 to 1912 has increased from 28,810,393 to 37,182,795, but, per ton, the output has decreased from 31.5s. to 29.9s., while the working costs have increased from 18s. to 18s.8d., the working profit decreasing from 13s.5d. to 11s. 1d. (There is a clerical error in Chart No. 2 in the working profit figures.)

The most significant figure, however, is that dividends in 1908 on 18,196,589 tons of ore milled were over half a million sterling greater than on 25,486,361 tons in 1912, despite the increase in the gross production of £8,000,000 in the latter period. The increase of 8d. in the cost and the decrease of 1s.8d. in the recovery makes a difference of 2s.4d. per ton as between the two periods. It will be noticed that the dividends over the period amount to only 71.8% of the profit declared, and to about 26.5% of the gross production. It must not be forgotten that there is an appreciable percentage of the amount distributed as dividend which is not profit. Some few companies have declared intermittent dividends, representing only a part replacement of capital, and then have stopped.

The charts clearly reflect, however, what has hap-

pened on the Rand in the past five years, and, to my mind, these figures may be taken as having an important bearing on the question of the diminution of grade and increase of cost, as depth is attained.

Decline in Production

According to Mr. Letcher, the decline of the Rand is to be of the same gradual nature as its rise, and in this he is possibly right. A precipitous decline could only be brought about by unfavorable conditions regarding labor, or foolishly selective mining, or some equally potent factor in the working of the mines. He does not emphasize the fact that the decline may be a great deal more gradual than the rise, owing to possible future improvements, by virtue of which the enormous tonnages of 3 to 4 dwt. ore of the Rand may be ultimately handled at a profit. If it should be possible to handle these ores, of which many millions of tons partly developed exist within the area of present developments—and no man will be bold enough to say that such things cannot come about—then there is a possibility of finding the Rand still in existence as an important mining district many years ahead.

Personally, I have the conviction that the Rand will die hard, and, as the grade of the available ores becomes lower and lower, necessity and invention combined will contrive ways and means of showing profits that, under the methods and general procedure obtaining today, would be quite impossible.

London, July 30.

H. S. DENNY.

[The question when to adopt selective, and when wholesale mining methods is a live one in many districts other than the Rand. We will be glad to hear from other of our readers.—EDITOR.]

Trent Agitators

The Editor:

Sir—In the article on Symmes agitators, published some time ago, it was claimed by the author that his agitator was as near perfection as any agitator could be, because of the fact that it started up freely after a shut-down of four hours and fifty minutes.

In connection with this matter I would like to call your attention to my experience with the Trent agitator here last night. There was a severe thunder storm and lightning struck the sub-station, demolished one of the switches, and short-circuited the line. As a result of this, the plant was without power for a period of fifteen hours, until ten o'clock the following morning. I was fully prepared to sluice out the agitating vats, but was surprised to find that after the pumps had been started and the agitators shaken a little, every one of them started and were running within fifteen minutes. The specific gravity of the pulp varies from 1.25 to as high as 1.35, and the ore that is treated contains a good deal of porphyry, which packs solid after a shut-down. I consider today's performance of the Trent agitator as remarkable and do not know of any agitator that would do the same thing.

WALTER TECHOW.

Virginia City, Nevada, July 22.

Special Correspondence

NEW YORK

THE MEXICAN SITUATION.—PRESENT AND FUTURE COPPER PRODUCTION.—ZINC PRICES AND BUTTE & SUPERIOR OUTPUT.— BUTTE MINING COMPANIES IN TROUBLE.—STEWART, FEDERAL AND UNITED STATES STEEL CORPORATION.

The leading topic of the week has been the relations between the United States and Mexico, and the message read to Congress by President Wilson has been thoroughly discussed, both at home and abroad. The stock markets regarded the outcome as favorable, as securities in Mexican enterprises advanced toward the end of the week, but generally the action of the administration has come in for criticism. European critics point out that the withdrawal of all Americans, leaving something like \$500,000,000 of assets behind, is scarcely practicable, and the firm and aggressive attitude taken by Sr. Gamboa has caused much favorable comment. The view held by some is that the elimination of Huerta would be a great mistake, since what is needed in Mexico is a man of sufficient force to control the situation, and during the months in which he has been tried out Huerta has given good evidence of possessing the necessary characteristics. To throw him overboard and begin again with an untried leader probably would mean repeating the incidents of the past half-year. The means by which Huerta acquired control of the government are repellant to Americans, but, on the other hand, our own means of acquiring the control of the Panama canal zone was not so blameless as to justify us being too particular as to the antecedents of the Huerta administration. It would seem better to tolerate the past of the present government than to follow a course of action which may lead to a repetition of similar occurrences. Meanwhile little has been accomplished beyond creating the impression that the United States is disposed to take a firm stand regarding Mexico, rather than attempting to ignore the turmoil to the south of us.

The market of electrolytic copper was firmly established at 16c. per pound by the end of August, a good deal of October and November copper having sold at that price. This figure was the one held abroad and cables from London on August 28 stated that dealers, who usually undersell the producers, had advanced prices to £74 10s. (16½c.), Aron Hirsch & Sohn quoting £74 5s. The latest report from the Lake Superior district was that 17 shafts had resumed hoisting. The Laurel Hill refinery is endeavoring to recover some of the output it lost when shut down by the strike earlier in the summer, but, even so, it is prophesied that the Copper Producers' Association figures will show a decline of 15,000,000 lb. in the output for August. The following table shows the refinery production and deliveries for the first seven months of this year:

	1913.	1912.	Increase, per cent.
Production (7 months)...	947,268,638	872,976,969	8.6
Deliveries (7 months)...	999,676,265	911,921,286	9.6
Excess deliveries	52,407,627	38,944,317	..

C. W. Barron returned from Europe last week and has given out the following statement: "Although Germany for two years has been trying to curtail industry and stop new construction, she has increased her consumption of copper more than any other country and is still at the maximum of consumption. This month there has been an active buying movement in the metal in England and Europe, and unless buyers now go slowly copper may sell sharply higher, until the Lake Superior mines can get over their strike and come into the market. It should not be forgotten in this connection that the Calumet & Hecla has been the sole American copper mining company to check sharp advances in copper. It has not been the policy of the Company to sell ahead, and with two smelters and its reserves it has usually been in a position to check a runaway market. Calumet is now powerless to check the market, if consumers take fright over the absence of copper reserve supplies of any consequence anywhere in the world. Recently copper

has been shipped upon express steamers to Europe at higher than ordinary freight rates because of the shortness of supplies." Looking at the matter from another viewpoint, it may be said that general business is now very dull, and the manufacturer will shortly have to adjust himself to the unknown effect of the new tariff. He is not insensible to the fact that Chino is expected to break its best previous record with an output of over 5,000,000 lb. in August. The Calumet & Arizona has blown in its new smelting plant and will raise its monthly output 5,200,000 lb. from the Calumet & Arizona ores, while the Shattuck-Arizona ore is expected to provide 1,000,000 lb. per month in addition; nearly a 50% increase over output last year. By the first of the year Inspiration will have a 600-ton mill at work, with its big mill coming in a year later. Braden is increasing its output, the Granby will blow in its smelter at Hidden Creek by the end of the year, while in the background looms Chuquicamata with its immense output, and the possibilities at Tanganyika as well. Until the selling outlook for manufactured products is better it is scarcely likely that consumers will stampede the copper market from the fear that they will not be able to secure copper to fill orders.

Spelter continues on its upward way, touching 5.8c. per pound for September, delivery on October 28. This makes boom times for the Butte & Superior, which has been rapidly increasing its output recently. At the middle of August it was treating 975 tons per day, and making an 86.5% recovery of the zinc in concentrate containing 48.9% Zn. The estimated tonnage milled during August is 30,000 tons, yielding 11,000 tons of concentrate, or over 10,000,000 lb. of zinc. The Mississippi Valley had always been the chief zinc-producing area, but the success of the Butte & Superior has shifted the centre of gravity of zinc production a good deal to the west. It will continue to take its way westward, for the zinc output of the Coeur d'Alene, Idaho, is rapidly growing as well, and California has immense resources of zinc ore which, at perhaps no very distant date, will become a market factor. Some Butte copper companies are having hard going. The Butte Central Copper Co. has been petitioned into bankruptcy by three creditors whose claims are \$300, \$400, and \$300 respectively. This concern, with a capitalization of \$2,500,000, has a remarkable set of names associated with it. The mine is called the Ophir, and, though not full of gold, was claimed to contain 1,000,000 tons of ore yielding copper, lead, zinc, silver, and gold. Among the directors are F. A. Cave and R. Forget; W. L. Creden being consulting engineer. After being thrown into bankruptcy for sums totaling \$1000, it seems evident that too much credence was placed on the estimates. The United Copper Co. is a man-sized mix-up, the claims filed against it amounting to \$2,745,375, and those against the Montana Ore Purchasing Co., one of its subsidiaries, being \$5,728,048. Justice Holt has recently appointed Henry D. Estabrook a special master to pass upon these claims, which have been filed with the receivers, J. S. Sheppard, Jr., and Addison E. Cudworth. The United Copper, it will be remembered, was the concern with which F. Augustus Heinze was connected, only to come to grief. While speaking of Heinze companies, it is interesting to notice that the Stewart Mining Co. has postponed its annual meeting until September 28. The directors state that present earnings justify dividends of 10c. per share per quarter; the next dividend being payable on September 15. Mrs. A. P. Heinze has just lost her suit against F. R. Hutton & Co., whom she sued to recover the amount of her margins, alleging that she bought United States Steel common stock on the assurance of the firm that it had inside information that the stock would advance, which it failed to do. Justice Whitaker held that a broker is not liable for expressing his opinion on the future course of the market.

The Federal Mining & Smelting Co. has been making good profits this year. It is reported that during the first eleven months of its fiscal year, which ended August 31, its earnings brought its surplus up to \$916,000, or nearly \$200,000 in excess of the \$720,000 required for its present dividend rate of 6%. Now that lead has advanced in price and spelter is high, the company should do even better. There is still 1¼% back dividends due on the preferred stock, which might have been paid this year if the directors had

thought advisable. The steel market has shown a marked increase of buying, the Steel Corporation showing an improvement of 30-35% as compared with three months ago. Present pig iron prices, averaging all districts, are about 25c. higher than when the lowest sales were made in June and July, and correspond, on the average, to the prices ruling in the middle of last August. The steel mills vary greatly as to their orders on hand, and the company which had the biggest tonnage ordered at the beginning now stands near the bottom. Some heavy rail orders are likely to be placed, among them that of the Pennsylvania railroad for 180,000 tons.

JOPLIN, MISSOURI

CARTHAGE MINES HAVE HEAVIER OUTPUT.—PLANTS OF AMERICAN ZINC, LEAD & SMELTING CO. RESUME.—ZINC AND LEAD NOTES.

Heavier production than usual is recorded from the mines of the Carthage, Missouri, district, where an extraordinarily high grade of zinc sulphide and some high-grade galena is produced. Much of the zinc ore brings better than the prevailing figure paid for 60% metallic-zinc lots. The S. Y. Ramage Co., which has been a conspicuous producer of the Webb City-Carterville district, has extended its field of activities to the South Carthage district. Different levels are being opened and hand jigs used to clean the ore. The Hermosa Mining Co. is operating on a lease of the Waddell Zinc Co.'s tract northwest of Carthage. A mill of 200 tons daily capacity has just been placed in operation. The Wise Guy tailing mill, treating residue from the rich old Vesuvius mine and the Linzee Hill Zinc Co., all northwest of Carthage, are other producers that are swelling the output of that camp. The ore of this region occurs usually in very soft ground. The roofs of the drifts are not substantial as a rule, and unusually heavy timbering is necessary. The district is producing close to 300,000 lb. of zinc ore weekly, valued at about \$7000.

Of much importance to the local district is the resumption of activities at mines No. 2 and 4 of the American Zinc, Lead & Smelting Co., at Webb City. Out of four large mines in the Prosperity group, only one has been working steadily through the era of comparatively low prices; the opening of the other two will give employment to about 250 men, and will increase the production of zinc concentrate about 400,000 lb. weekly. The lead-ore production will also be increased. The mines were closed because of low prices for ore. The drifts, however, have been kept drained and the task of resuming work was not difficult. The mines are equipped with mills of 400 tons daily capacity. A thin sheet-ground formation, occurring at a depth of 190 to 210 ft., is worked. The mill recovery is about 2.5% zinc concentrate and 1% lead concentrate. The bulk of the zinc ore is used by the American company in the manufacture of metal and is smelted at the Company's plants at Hillsboro, Illinois, and at Dearing and Caney, Kansas.

The Kansas City Zinc Co., operating on a lease of the Rusk land in North Joplin, has opened a zinc deposit at a depth of 140 ft., and a remodeled mill, moved to the lease, has just been placed in steady operation. The lease was worked to some extent by the Big Irish Mining Co. a year or more ago, but the present development is in 'virgin' ground to the north of the old workings, while some distance to the east another shaft has cut the same formation, and this is to be connected with the mill by a long inclined tramway. The ore contains about 10% iron pyrite, for which a deduction is made, but the richness of the zinc sulphide in the mill ore overbalances the presence of the undesirable element. The ground is soft, some timbering being necessary, although some of the drifts have substantial roofs.

On the Hemphill land, Belville, northwest of Joplin, an open-cut near Turkey creek is showing a workable deposit of tripoli, a mineral used in the manufacture of scouring and cleaning compounds. Preliminary development is being conducted by a Joplin company with a view to placing the property on a productive basis. This is the only occurrence of this mineral discovered near Joplin. A large deposit

at Seneca, Missouri, twenty miles southwest of Joplin, is now being extensively worked.

A lead ore discovery, apparently rich, is being worked by Edward Buxton and associates on a lease of the Charles Schifferdecker land, nine miles east of Joplin. In view of the fact that this is in a virgin territory where little mining has been done, the outcome of the operations is being watched with much interest. In drilling, the ore was cut at a depth of 50 ft. and extended down to 100 ft. The formation was shown in a number of drill-holes. The ore is 'free' in character, occurring in a talcose formation, and can be treated on hand jigs. It is estimated that it will yield close to 5% lead, although there are streaks of several feet in thickness which could be worked, and yield more than 20% lead. W. G. Stevens and others, of the Betsy Jane Mining Co., who have been drilling this land, have moved their prospecting rig to a point one-fourth

PROSPECTING WITH A KEYSTONE DRILL, JOPLIN, MISSOURI.

mile north of the lead-ore development and have started their first hole.

For the first time in years a number of mines have been forced to suspend operations because of a water famine. Mines that usually keep one or more large pumps at work steadily, have gone completely dry, and in some instances it has been found impossible to procure enough water to carry on milling operations. Prospect drillers have also had an extra demand for their services, the call coming from many farmers whose wells have also gone dry. The use of churn-drill rigs in sinking deep wells for water is common throughout the district at this time.

Zinc and lead ores at Joplin, Missouri, and adjacent districts are bringing better figures than at any time since the first part of the year, the former product commanding \$48 to \$50 per ton, basis of 60% metallic zinc, at the beginning of September, while the extra choice ores sell as high as \$53. Spelter at East St. Louis is quoted strong at \$5.75 to \$5.85. Prices are low when compared with the record figures of a year ago, when for the corresponding week of 1912 zinc sulphides brought \$52 to \$56, basis, with choicer grades commanding as high as \$59. Metal was quoted at 7.05c. per pound. Lead ore is stronger at \$58 per ton, while pig lead, East St. Louis, is quoted at 4.75 to 4.85c. per pound. For the corresponding week of 1912 ore brought \$61 and metal sold for 4.775c. per pound. Calamine brings \$22 to \$24, assay basis of 40% metallic zinc, with choicer grades selling for as high as \$30. A year ago the range was \$29

to \$31, with a top for choice lots of \$36. Zinc-blende production is now close to 5000 tons, lead ore about 750 tons, and calamine about 400 tons per week.

BOSTON

LAKE COPPER CO.'S AFFAIRS.—BOSTON & MONTANA DEVELOPMENT CO. AND THE BUTTE, WISDOM & PACIFIC RAILWAY.
—BUTTE CENTRAL, TONOPAH VICTOR, ALASKA GOLD MINES, AND TUOLUMNE.

The expected happened when the directors of the Lake Copper Co. met in Boston a few days ago and called an assessment of \$2 per share on the stock, payable September 9. This is the first time the stockholders of this Company have been assessed, and with the payment of the present levy the stock will read "\$5 per share paid in." The stock has the usual Lake par value of \$25 per share, and 100,000 shares. Lake made the high record of \$94.50 per share and has recently sold down to \$6. Its history has been one of great vicissitudes, as it was proclaimed a second Calumet & Hecla and afterward a worked-out property. The formation of the famous Lake lode has proved to be irregular, and this has hurt the Company's market standing. About three years ago, after the Paine management assumed control of the property, 13,500 shares of treasury stock were offered at \$35 per share, the underwriters, Hayden, Stone & Co., getting a commission of \$2 per share, the offering netting the Company \$443,850. Including the present assessment, Lake has had over \$1,000,000 spent on it, and is now selling at a market valuation of between \$600,000 and \$700,000. Few mines ever had a more variegated and checkered history, and the remaining solution seems to be a general consolidation of South Range properties in order to keep within one management the 'elusive' Lake lode.

The Boston Stock Exchange and Curb, following the example of New York and Philadelphia markets, observed Saturday, August 30, as a holiday, preceding Labor Day.

The Boston banking interests which are financing the Boston & Montana Development Co. and its subsidiary, the Butte, Wisdom & Pacific Railway, have received word that W. R. Allen, president, and W. C. Siderfin, vice-president, have made an automobile trip of nearly 300 miles over the route out of Butte which will be covered. The road will be about 128 miles long, including two spurs from the main line to connect the Elkhorn district in Beaverhead county and the French Gulch district in Deer Lodge county. About three miles from Divide, on the Oregon Short Line, is the dam of the Big Hole Power Co.'s plant, where the railroad company has a corps of engineers now in camp surveying the line. At this point there is about a mile of difficult engineering to be done to provide a roadbed on the side of the mountain. Outside of this point, it is said that the average grade of the road in its entire length is less than 1%. The road will open the country around Bannack, the first capital of Montana when it was a territory, and the scene of the first rich placer-gold discovery in Montana. A stampede resulted up the gulches to the north, culminating in Butte. The president, Mr. Allen, former lieutenant-governor, is known throughout Montana as 'Governor,' and the vice-president, Mr. Siderfin, is general manager of W. A. Clark's business interests. The road will open the Big Hole basin, a valley of about 1000 square miles, this being the only rich valley in Montana which has no railroad.

Butte Central will have to undergo reorganization, and the stockholders are being advised to that effect. The Company is involved in debt. It has a good mill, but is unable under present conditions to supply it with ore averaging more than \$5.50 per ton. This is about half the average expected by the management, and places the Company in a position where it cannot make a profit with a 100-ton plant. The mill, however, which is all paid for, is a splendid asset, opening the way for the treatment, by combined concentration and cyaniding, of Butte argenteriferous ores which formerly went to waste. It is believed that this will bring about an important feature of Butte

operations, and to the ill-fated Butte Central the credit may be given.

The Boston Curb has listed for trading in its unqualified department 1,200,000 shares, par value \$1, of the Tonopah Victor Mining Co., of Tonopah. This is the second Tonopah stock to be admitted to trading on the Curb. Tonopah Victor is sinking the main shaft down nearly 600 ft. in cap rock. The president of the Company is John G. Kirchen, general manager of Tonopah Merger and Tonopah Extension, and the treasurer is Key Pittman, United States Senator from Nevada. Seeley W. Mudd, of Los Angeles, is one of the directors.

Alaska Gold Mines stock has recently been under pressure, a block of several thousand shares having been liquidated, but shows recovery.

Boston takes considerable interest in the losing fight which has been made by Tuolumne officials to increase the capitalization of that Company from 800,000 to 1,500,000 shares and in the expansion to acquire the Butte Main Range property, a prospect of considerable value in the Butte district. The opposition to the president, Mr. Hickey, and his associates was led by Lee Mantle, former senator, who had a clean-cut victory. It was foreseen that the Tuolumne plans would not go through, and the officers of the Butte Main Range Co., who are largely the same as those of Tuolumne, met and withdrew Butte Main Range from consideration in the deal. This was prior to the Tuolumne meeting and made the defeat of the expansion plans a certainty. It is believed here that the outcome of the fight between Messrs. Mantle and Hickey places the responsibility of Tuolumne's future upon Mr. Mantle, an unsought and unexpected honor, and will logically relieve Mr. Hickey of that burden. The fight was a fast and furious one, and came to a climax by the Mantle faction preferring charges of irregularities in the Tuolumne management, and an investigation has been ordered. The Tuolumne group is the largest local independent one in Butte, but has met defeat in trying to make Tuolumne, a rich but small property, larger than it really is. The stock of Tuolumne has been traded in at times with some activity on the Boston Stock Exchange, and it is supposed that there is some scattering of the shares, but the control is held in Butte. Mr. Mantle is the owner of 5000 shares.

TORONTO, CANADA

DOME MILL EXTENSION.—DEVELOPMENTS AT THE HOLLINGER, PEARL LAKE, AND BURNSIDE MINES.—NORTHERN CUSTOMS CONCENTRATOR BEING ENLARGED.—AFFAIRS OF THE CANADIAN IRON CORPORATION.

The construction of the addition to the Dome stamp-mill is progressing rapidly, and it is anticipated that the 40 new stamps will be in operation early in 1914, increasing the capacity from 370 to upward of 650 tons per day. A change will be made in the process of treatment, and six sand-leaching vats will be added to the equipment.

The Hollinger company has opened on the 425-ft. level its No. 1 vein, which had dipped out of the winze. It is reported to be as rich as in the upper levels. The winze will be sunk another 125 ft. No. 4 vein is opening well on the 300-ft. level. The shaft on the Dixon property, owned by the same interests that control the Hollinger, will be sunk from 235 to 500 ft., with cross-cuts at every 100 ft. Development will include driving from the Hollinger, work having been already commenced at the 100-ft. level.

A find of rich ore has been made at the Pearl Lake, in a raise from the 400-ft. level. The ore shows a good deal of free gold. This is stated to be the first time that free gold has been discovered at this depth. The discovery and the production of fine specimens of the ore caused a revival of interest in the stock market, and an active demand for shares. The Pearl Lake shaft is down to 725 ft., which is the lowest depth reached in the Porcupine district.

Shareholders of the Dome Lake, at a meeting held here on August 25, ratified the proposed increase in the capitalization from \$500,000 to \$750,000, but refused sanction to

the proposal of the directors to offer \$100,000 in shares for sale at 35c. Strong dissatisfaction with the course of the management was expressed, and action postponed until fuller information as to the condition of the Company was forthcoming. At the Burnside, in the Kirkland Lake area, some good surface finds have been made. A cross-cut has been started at the 100-ft. level to cut the vein, which dipped out of the shaft at 50 ft. depth.

The Northern Customs Concentrator has placed with the Power & Mining Machinery Co. an order for 80 stamps, to be delivered at Cobalt within 60 days. The Cochrane has adopted a policy of deep mining. This mine has taken out some high-grade ore from and above the 200-ft. level, but the ore-shoots have all been short and quickly exhausted. The shaft is to be sunk from the 200-ft. level to reach the diabase formation, which in this neighborhood underlies the Keewatin at a depth of about 600 ft. Levels will then be driven through the Keewatin to cut the main vein. At the Cobalt Lake underground exploration has been undertaken to prospect several acres at the north end of the property hitherto undeveloped. The work will be done north and west of the old No. 4 shaft on the east side of the lake. A cross-cut will be driven at the 300-ft. level across the lake to cut fault veins, and another will be driven north down the lake centre at the 225-ft. level.

The Canada Iron Corporation has been placed in the hands of a receiver, F. F. White, of New York, pending the reorganization of its finances. It has been adversely affected by foreign competition since the abolition of the iron and steel bounties, and has found difficulty in making collections. The directors concluded that as there seemed no prospect of relief by favorable tariff changes, the best course was to reduce fixed charges by reconstructing the finances. The Company's headquarters are at Montreal, and it has iron mines at Egansville and Bessemer, Ontario, Bathurst, New Brunswick; and Torbrook, Nova Scotia; and furnaces and foundries at Midland, Hamilton, and Fort William, Montreal, Londonderry, and several other widely scattered points in eastern Canada. Its outstanding securities consist of first mortgage bonds, \$2,920,000; consolidated bonds, \$1,717,933; preferred stock, \$2,909,000; and common stock, \$4,832,300. Most of its securities are held abroad. The plants continue in operation, and it is stated that business will be conducted without interruption until the reorganization is effected.

BUTTE, MONTANA

BUTTE & SUPERIOR ZINC ORES.—BUTTE, WISDOM & PACIFIC RAILWAY.—BUTTE CENTRAL AFFAIRS AND THE MINE.—MINE RESCUE WORK.—TUOLUMNE COPPER COMPANY.—BUTTE MINERS AIDING MICHIGAN STRIKERS.—BUTTE & ZENITH SHAFT SINKING.—EQUIPMENT COMPLETE AT BELMONT SHAFT OF ANACONDA COMPANY.

Good reports continue to come from the zinc mill of the Butte & Superior Copper Co. Considering the published results the success of the zinc industry at Butte seems assured, and it appears to be high time to prospect some more of the many large manganese veins of Butte in search of other zinc orebodies.

Of local interest to the mining industry is the proposed construction of a new railway in Beaverhead county, Montana. The line is being surveyed from Divide Station, on the Oregon Short Line, to Wisdom in the Big Hole basin. A branch line will be laid up Wise river to the Elkhorn mining district. It is probable that the promoters of this enterprise have visions of larger things still, and may attempt that difficult and expensive engineering task of continuing through Idaho to Boise and further, for the name suggests the Pacific Ocean as the final terminus of the line. As the crow flies, a southwest line from Montana to California would seem to have strategic advantages from the traffic-man's point of view, but field engineers state that the vertical components of a railway through that part of Idaho are something sad to contemplate. In any case the Butte, Wisdom & Pacific railway promoters want to get rail transportation to their mines at Elkhorn, and incidentally will gather in what tonnage they can from the

stock raising and lumber communities of the Big Hole basin.

According to press reports the Butte Central company is still trying to blame its troubles on makers of stock-market raids and others. It is claimed that 'bear' raids scared off the money supply at just the wrong time. To an on-looker it would seem, however, that the true cause of financial fright was the failure of the expected returns from the mill. A first-class mill was erected under competent direction and was operated for some time; then the crash came, and it seems hard to get away from the conclusion that the real trouble lay in the disappointing returns from the ore milled. With the ore in the mine as claimed, and the mill in operation why couldn't the stockholders rest on their oars and let the mill do some of the paying? Now that Boston creditors have brought bankruptcy proceedings against the property, something may yet be done. A reorganization may be effected and a fair trial made for a zinc mine. Promising manganese veins exist in the property, and no one knows but what zinc orebodies similar to those of the Butte & Superior or Elm Orlu mines might be developed. Comparing the veins with those on Anaconda hill, and hoping for copper at depth seems hardly justified, because no typical east-west manganese vein, such as the Ophir of Butte Central, has proved profitable in copper at any depth. Several such veins have been developed sufficiently deep to satisfy engineers conversant with Butte that these veins are not promising for copper.

Mine operators in Butte are taking an active interest in the government system of mine rescue and first-aid instruction. Oxygen helmets are in constant use in several of the Butte mines, on account of troublesome mine fires. The companies are assisting those in charge of the Mining Bureau's rescue car in every way possible. This has resulted in many of the mine employees becoming fairly well skilled in the use of the necessary apparatus. There is no doubt that many lives can be saved by proper use of the information offered by these government specialists.

The Tuolumne Copper Co. is also having troubles. It is to be commended, however, for not trying to hide them from those interested. In the first place comes a statement from the secretary, Mr. Harrington, to the effect that the Company lost \$8000 on its mining operations last year. This same statement acknowledges the fact that the directors saw fit to declare \$160,000 in dividends during this depressing period, leaving but \$37,000 on hand with which to operate a copper mine. Also, the scheme of some of the directors to take over another prospect and refinance Tuolumne has met with such strenuous objections on the part of many stockholders that it has apparently been dropped. And as a further reflection of internal troubles, the superintendent, Mr. Sheehan, has resigned, and his successor has not yet been made known. At present Tuolumne is shipping about 100 cars of ore per day, just about sufficient in value to meet operating expenses.

The miners' union at Butte is sending \$14,000 per month to the aid of the striking copper miners of Michigan. This fund is secured by a monthly assessment of \$2 from every miner in Butte. Outside of the benefit to unionism which this fund is intended to give, the argument is brought forward that the furthering of the Michigan strike will act directly for the benefit of the Butte miners. The price of copper is supposed to be advancing because of the curtailed production from Michigan, and should this curtailment bring the price of copper to 17c. per pound, the Butte miners will receive 25c. per day more wages. In other words, the theory is that by abetting the Michigan strike to the extent of \$2 per month the Butte miner will better his own paycheck by the sum of \$15 per month. This argument borders on high finance in its reasoning, but is not laying much stress on the financial distress of the Michigan miner.

The Butte & Zenith Copper Co. is to resume sinking its shaft west of Butte. The cross-cutting, which was done from the 500-ft. level, is claimed to have opened promising ground, and the shaft is to be continued to the 1000-ft. level.

East Butte Copper Mining Co. has extensive improvements under way which will result in an increased production. It is planned to have this work completed by the beginning of 1914. The smelter is being enlarged to double

the present capacity, the concentrator is being remodeled and enlarged, and new underground work is to be undertaken. The old No. 1 mine, the work on which was suspended some six years ago, is to be reopened and deepened, and an electric hoist is to be installed there.

RHODESIA

LABOR IN RHODESIA AND THE RAND.—GLOBE & PHOENIX AND BUSH TICK MINES.—ALTERATION TO LAW DEALING WITH PLACER MINING.—LOWER GWELO DISTRICT PROSPECTS.

While mining affairs in the Union of South Africa have been under a cloud for the past six weeks, the mineral industry in the adjacent territory to the north of the Limpopo river has made good progress. All things considered, the last two or three monthly outputs are admittedly satisfactory, and in regard to the development, and more particularly the equipment, of the large 'new' mines of the country, the Shamva, Cam & Motor, and Falcon, good work has recently been achieved. Rhodesia is as yet too young a country for 'trades unionism.' The industrial unrest so noticeable in the Union of South Africa today has not spread to the British South Africa Co.'s sphere of influence, and, having regard to recent events

exceptionally rare on the Witwatersrand, is common in most of the Rhodesian goldfields.

In short, the Transvaal miner has substantial advantages over his brethren in the north, but whereas the man on the Rand appears to be forever discontented, the Rhodesian is generally a cheery soul, quite prepared to take on a contract in a bad end, to slide down an ancient working, or to pump a neighbor's claim, as the occasion requires. The strike on the Rand is not likely to have much effect on the white miners of Rhodesia. But since the Union Government has prohibited recruiting until the present period of industrial unrest is over, the strike is likely to have a beneficial influence on Rhodesian mining in so far as natives are concerned. Large numbers of 'hoys' who under normal conditions would go to the Rand compounds, are now likely to find employment at the Rhodesian mines, and as a number of new mines are due to commence treatment operations in Mashonaland before the close of the year, these natives deflected from the Rand by the strike will be a valuable acquisition to the country.

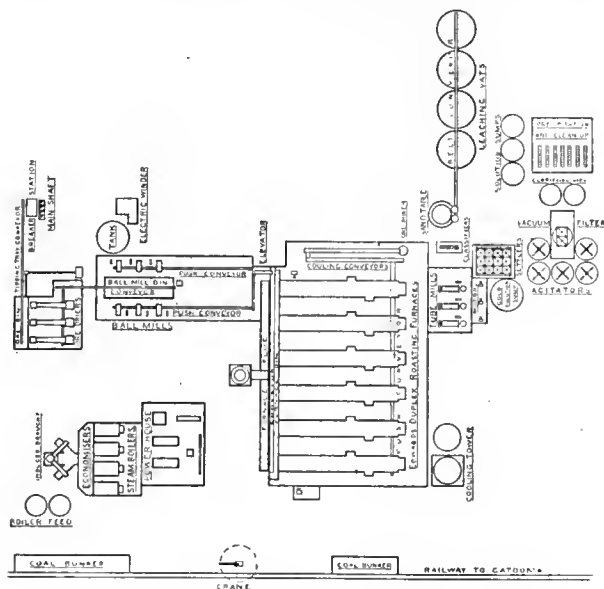

The gold output of Southern Rhodesia for June has been declared at £240,303, which, considering the shorter running time, may be said to compare favorably with a production of £243,452 in May. During the first six months of this year the gold output of the country has been worth £1,412,170, as compared with £2,707,369 in the corresponding period of 1912 and £2,647,896 in the first six months of 1911. Production of minerals other than gold in these three periods was: 1911, £242,863; 1912, £257,230; 1913, £109,217. These figures show that while the rate of output in regard to gold has shown advance during the first half of the year, the production of other minerals records a slight decline. Among 'other minerals', chrome iron ore occupies the leading place, and since the quantity and value of chrome-iron ore raised is dependent on shipping facilities at Beira, the decrease in 'other minerals' is probably more apparent than real.

The largest contributor to the gold output during June was, as usual, the Globe & Phoenix. With 40 stamps and 10 pans at work, this mine milled 6450 tons of ore yielding from the mill £32,168, from concentrate £3347, from tailing £4392, and from slime £2803.

The Bush Tick Mines, Ltd., is a property that has been recording improved returns during the past month or two. This mine is under the Hollins control, and a few months ago the whole surface equipment was reorganized and six Nissen stamps were added to the mill. The March output was 834 oz. gold, and the production for May amounted to 1068 oz. with a total value of £5513. A stamp-duty of 10.13 tons per head per day was obtained. It is important to learn that sinking operations have been resumed in the two main shafts of this property. It is reported that 'development values are improving at depth.'

The Government of Southern Rhodesia has recently been considering alterations to the existing law with a view to giving more favorable chances to men staking placer gold areas. During the past year or two the production of gold as the result of alluvial working in Rhodesia has been practically of a negligible quantity. The Department of Mines does not anticipate the development of any important placer fields; but it is recognized that the gravel in some rivers, notably the Mazoe, is well worth washing for gold.

The Lower Gwelo mining district is again attracting the attention of Matabeleland prospectors, and after a fairly lengthy period of comparative idleness, it is satisfactory to observe that mills are working at most of the old points of call between Gwelo and the Gothic again. The R. W. Syndicate owners are working the Rocksand and Sceptre mines. The 10 stamps on the Shamrock are being worked by Crampin and Masters. The Gretna Green and Alannah mines are also in this neighborhood. On the latter, it is reported, a rich ore-shoot has recently been opened, and a 5-stamp mill is in course of erection. It looks, indeed, as if the lower Gwelo area will become one of the most productive districts in eastern Matabeleland in the near future.

PLAN OF CAM & MOTOR NEW PLANT OF 15,000 TONS MONTHLY CAPACITY. THE ORE CONTAINS GOLD AND ANTIMONY AND THE MILL HAS BEEN DESIGNED FROM THE BEST PRACTICE AT KALGOORLIE.

on the Witwatersrand, Rhodesian mine-owners must feel devoutly thankful that the labor agitators have not yet attempted to bring about a state of anarchy and industrial paralysis in the several goldfields of Matabeleland and Mashonaland. There are, of course, vast differences between the white labor problems of the Transvaal and of Rhodesia. To begin with, the miner of Rhodesia is a very different person from the miner of the Main Reef group of mines. He is a much more happy-go-lucky individual and not imbued with the truculent feeling of 'I'm as good as you and a jolly sight better' which is too often the attitude of the Rand miner to managers, mine captains, and shift bosses alike. The average worker connected with a Rhodesian mine is a man who has a knowledge of other things than actual mining. He is a prospector; as often as not, a hunter and trader as well. In the dry or winter season many Rhodesian miners 'trek off' into the bush, bent on finding mines of their own. Some of them strike it lucky, others do not and have to return to some employment. But in any circumstances, there is invariably a better *esprit de corps* in the mines of Rhodesia than on the Witwatersrand. On the average, Rhodesian miners earn, if anything, less than miners on the Rand, and in Rhodesia living expenses are appreciably higher than in the Union of South Africa. The phthisis evil is practically unknown in Charterland, but, on the other hand, malaria, which is

General Mining News

ALASKA

JUNEAU

The Alaska Gastineau Mining Co. will add to the electrical equipment of its plant two 1750-kva. alternating-current generators with a 50-kw. motor-generator exciter set, a 540-kva. induction motor with 22-kw. exciter, six 600-kva. water-cooled transformers, switchboard panels, and accessories. All the apparatus has been ordered from the General Electric Company.

VALDEZ

Letters from the North and returned stampedeers bring unfavorable news from the Shushanna goldfields. Prospectors going toward the camp met discouraged men returning, and many turned back. Reports state that about \$15,000 has been taken out on the discovery claim, but trenching above and below the claim shows barren ground. Food is said to be at a high price, and flour sells at \$1.75 per pound.

ARIZONA

COCHISE COUNTY

(Special Correspondence.)—G. P. Sterrett, a turquoise gem expert employed by the United States Government to report on all precious stones found anywhere in the country, has been in the eastern part of the county lately investigating such properties. The turquoise mine near Courtland has received a great deal of attention, and an examination by Mr. Sterrett convinced him that it is a valuable mine. The fineness and quality of the gems is considered the best in the United States. Mr. Sterrett was greatly surprised at the spectacle of the great quantity of blue stones so eagerly sought for by Eastern collectors of gems. Joseph Mulheim and a number of other prospectors and mining men have taken an option on a zinc property in the Dragoons, west of Tombstone. It is a zinc deposit, the equal of which has not been found in the county. Development work of a preliminary character is under way at present, and indications are promising. Secrecy is being rigidly maintained by Mulheim and his partners in the venture as to the exact situation of the new zinc district, as they are busy securing options and bonds on adjacent territory.

Benson, August 28.

Concreting the Junction shaft of the Calumet & Arizona was finished during the past week. A considerable amount of work has to be done at the surface in the shape of new equipment.

A meeting of the Copper Queen Benefit Association was held during the past week. The report showed that the Association is in a strong position and that there has been a noticeable decrease in the more common accidents, fewer claims along this line having been paid in many months. This is the first tangible result of the widespread 'safety first' movement which is daily being extended more and more in the district.

GILA COUNTY

(Special Correspondence.)—Superior Judge Shute sustained the New Keystone company's demurrer to the Inspiration company's suit for condemnation of right-of-way for a tunnel through the New Keystone property, upon the grounds that it could not be considered a public utility within the statute. Notice of appeal was filed by the plaintiff company, although it failed to avail itself of the opportunity granted by the court to amend its complaint. Local discussion is generally to the effect that the present feeling displayed between the two mining companies, the Inspiration and the Miami, is due to the action of the Inspiration in securing the South Live Oak property by purchase, despite the fact that the Miami company was the only bidder that went to the expense of thoroughly examining the property. Whether the Inspiration will continue its efforts to secure a right-of-way for a transportation tunnel through the New Keystone, or will arrange for another method of ore extraction, is not yet known.

Miami, August 30.

MOHAVE COUNTY

With the new concentrator of the Arizona Southwestern Copper Co., at Copperville, in operation, another great step has been taken in mining development in this county. The mill is of 200-ton daily capacity. Regular shipments of concentrate will be made from now on. Six auto-trucks have been ordered, and they will be used with the one purchased more than a year ago. The trucks will carry the concentrate to Yucca station, where it will be loaded on railroad cars for shipment to the Needles smelter.

PIMA COUNTY

Thomas M. Park, manager of the Elephant Head mine, has received two 6½-ton Sauer motor trucks for use in hauling ore from the Elephant Head mine in the Santa Rita mountains to the nearest railroad point on the Tucson-Nogales line.

YAVAPAI COUNTY

Reports from that portion of Hassayampa district lying east of Copper basin are most encouraging, the miners of that district being busy in the development of their properties. At the Climax, during the past few weeks, water for milling purposes has been scarce. The Lion vein of this property has been opened from No. 4 and 5 adits. The C. B. S. company, whose stockholders are mainly the same as those of the Climax, has also obtained good results from the limited amount of work so far done. A vein was cut in the shaft, assaying 9% copper, \$10 silver, and \$2 gold per ton. In the Big Bug district, the Humboldt Consolidated company is opening rich silver ore.

YUMA COUNTY

There are reports of the cutting of gold-bearing ore on the 450-ft. level at La Fortuna mine, thirty miles north of Yuma. It is stated that the ore assays \$400 to \$500 per ton.

CALIFORNIA

BUTTE COUNTY

Emil Autram and L. Fredericks, two miners employed at the Success gravel mine at Thompson's Flat, had a narrow escape from drowning in the lower levels of the mine, on August 27, when they broke through into an old drift which was filled with water.

NEVADA COUNTY

The new shoot on the 300-ft. level of the Oustomah mine is yielding some high-grade ore which adds considerably to the prospects of the mine, as the ore is in new ground. The shaft is being sunk to 1500 ft. E. C. Klinker is manager. The Eagle Bird mine at Maybert has been bonded by W. M. Wilson, owner of the property, to the California Eagle Bird Mining Co., of which Mr. Klinker is the general manager. The new Company will thoroughly develop the property. About 20 men are employed at the mine, sawmill, 10-stamp mill, and other work. The three-compartment inclined shaft is 800 ft. deep and is filled with water within 50 ft. of the collar, but it is estimated that this can be pumped out in 30 days. The Forest Service has sold to the Tightner Mines Co. 30,000 stumpage feet of standing timber on Section 36, the same adjoining the patented section on Oregon creek which the Company bought a few months ago from the Cole estate. The concrete foundations for the new stamps and concentrating tables have been set, and a large platform erected adjacent to the site for the new annex to the mill.

It is stated that rich ore has been opened in the Pennsylvania mine, operated by the Pennsylvania Gold Mines Co. George W. Starr is superintendent.

SHASTA COUNTY

(Special Correspondence.)—The Mammoth Copper Co. is working 8 machine drills at the Stowell mine, situated between the Mountain Copper and Balaklala holdings, and recently opened a large orebody showing good copper ore. A new and interesting situation in the smelter-smoke question has recently developed in Shasta county. The crops have been remarkably large this year and generally free of any insect ravages such as developed in many neighboring counties. It is claimed by many disinterested people that this pleasing agricultural condition is due to

the sulphur that has been deposited on the soil by the copper smelters, and that operation of such works is of direct benefit to agriculturists by increasing fertility of soil and banishing insect life from trees and crops. That the farmers are beginning to appreciate the value of the copper-mining industry to Shasta county was recently evidenced when the Farmers' Protective Association issued an open letter declaring its friendliness for the copper miners and its desire to aid in an amicable solution of smelter-fume troubles. Coincident with the Hall desulphurizing experiments at Coram and Field process trials at Redding, the action of the agriculturists has created a most favorable impression. Frank M. Leland has invited the farmers to inspect the installation and operation of the Hall plant at Coram, in order to satisfy themselves that the Balaklala Copper Co. is using every endeavor to prevent escape of objectionable fumes.

Redding, August 25.

R. E. Scott arrived at Coram from New York and Paris, and will remain until the Hall process is tried out at the Balaklala smelter. Mr. Scott is familiar with the Hall process, as he installed it successfully at some pyrite mines in France. His advice is appreciated by the Balaklala management at this time. The aerial tram-line was started on August 28 and ore is now coming from the mine to the smelter. The gas producer, a part of the Hall process plant, was started on August 26.

SIERRA COUNTY

A stope, 800 ft. farther northeast than any previous development in the Sierra-Alaska mine, at Pike City, has opened some rich ore. It is only 300 ft. from the surface. The water in the North Fork mine at Forest was lowered 15 ft. during the week. It is expected, however, that from now on the rate will be more rapid, with the probability that the drainage will be accomplished by about September '10. People from Alleghany confirm the report of rich ore in the Eldorado mine. It was made in a raise from the main working adit, at a height of 150 ft. The vein is 3 ft. wide and is rich in free gold and arsenical pyrite. Over \$1600 worth of coarse gold was recovered after the blast that opened the ore. It has since been exposed to 12 ft. in height and is undoubtedly the same shoot that was mined in former days 350 ft. higher in the surface workings. The shoot pitches south. The mine is being worked by Fessier Bros. They started the 10-stamp mill during the past week.

The Nissen stamp-mill is being moved from the Red Star to the Sierra del Oro (Ironside) in the head of Jim Crow cañon. The mill will be erected at once at the Sierra del Oro and used to crush ore from that mine. The Nissen mill consists of a single 1500-lb. stamp in a circular mortar and is practically new, having been run only a short time at the Red Star. One or two good concentrators will be installed to save the sulphides, and the machinery will all be run with a gasoline engine. The Sierra del Oro is owned by Redding, McCormick & Mayer, and Mr. McCormick is in charge of the development. An air-compressor and machine-drills have been installed at the Alhambra at the head of Jim Crow cañon.

TUOLUMNE COUNTY

(Special Correspondence.)—The recent heavy storms in the high mountains have caused a temporary suspension of operations at the Kanaka bar claim, on the Tuolumne river, near Jacksonville. The gravel washed so far has given good returns, and work will be resumed as soon as the swollen stream permits. It is reported that a deal for the sale of the Uncle Sam and Fifth Ward mines, situated near Arastraville, was consummated this week and that the purchase price, said to be \$20,000, will be paid in full immediately. Robert Marshall, of Sonora, has for many years been the owner of the properties. A promising claim is being developed near the Black Oak mine by the Nicholls Bros. and Thomas Webster, of Soulsbyville. Some high-grade ore is being mined. A party of San Francisco mining men, accompanied by R. C. Kennedy of that city, inspected the old Starr King mine, east of Tuolumne, this week with a view to reopening the property. Development work is in

progress at the Louisiana mine, north of Tuolumne. An assay of some ore lately opened showed \$90 per ton. Rich gravel has been uncovered in the Jungerman claim, situated above Pine Log, on the south fork of the Stanislaus river. The property is being developed by Thomas A. Lawson, Louis Hansen, and the Boenig brothers. A controlling interest in the Alameda mine has just been acquired by Charles Fitzgerald, who expects to succeed shortly in reopening the property for further development. Fire in the compressor-room at the New Albany mine this week did damage to the amount of several hundred dollars.

Sonora, August 30.

COLORADO

CLEAR CREEK COUNTY

It is reported that the Big Five Tunnel & Ore Reduction Co., of Idaho Springs, which contemplates the erection of a concentrating mill, will wait until the Edison mill at the Waldorf mines is completed, and if it proves the success anticipated, a similar mill will be erected by the Company. A large ore-house is being erected at the dump of the Bard Creek mine, preparatory to breaking down ore during the winter.

JEFFERSON COUNTY

It is proposed to reorganize the North American Smelter & Mines Co., and a new company is to provide \$500,000 working capital. This Company proposes to improve and reopen the old Carpenter smelter at Golden and to build a new 300-ton combination mill to work in conjunction with the smelter. It will obtain its ores from Gilpin, Clear Creek, and Jefferson counties, where it owns a number of mining properties. The old company went into liquidation in October 1912.

OURAY COUNTY

The machinery for the installation of the flotation process at the Atlas is expected shortly to arrive at Ouray.

SAN JUAN COUNTY

Plans have been drawn for the erection of a 500-ton plant to treat the tailing from the old mill at the Silver Lake mine. A. R. Wilfey will test a new concentrating table in this new plant. The examination of the Buffalo Boy properties of the Continental Mining Co. was completed during the last week in August by the engineers who have been there for the past three weeks. The samples were taken, carefully marked, and shipped to Nevada to be sampled and assayed. The results will not be known for several weeks yet, as the last of the samples are just being prepared and shipped.

TELLER COUNTY (CRIPPLE CREEK)

According to local statistics, the Cripple Creek district in August produced 85,381 tons of ore with a gross value of \$1,251,809, as follows:

Plants.	Ore treated, Av. val.		Gross val.
	tons.	per ton.	
Golden Cycle	33,500	\$20.00	\$ 670,000
Portland (Colorado City)...	10,000	22.00	220,000
Smelters	4,000	65.00	260,000
Portland (Cripple Creek)...	15,800	2.50	39,500
Stratton's Independence	11,286	2.67	30,133
Colburn-Ajax	5,580	3.20	17,856
Gaylord-Dante	1,400	3.00	4,200
Kavanagh-Jo Dandy	1,600	2.10	3,360
Wild Horse	1,165	4.00	4,660
Isabella	750	2.00	1,500
*Rex M. & M. Co.	300	2.00	.600
Total	85,381		\$1,251,809
*Dump ore experiments.			

Dividends totaled \$80,000, made up of \$30,000 from the Golden Cycle and \$50,000 from the Elkton Consolidated companies.

Lessees at the Victor Gold Mining Co.'s property have opened what is thought to be the East Victor vein, a heavy producer, on No. 8 level, at a depth of 650 ft. The vein dips southwest and assays up to \$100 per ton in gold.

IDAHO

BONNER COUNTY

Concerted action by the mining men interested in the Pine Creek district to combat the encroachments of homesteaders is planned as one of the chief matters to be taken up by the Wardner-Kellogg chapter of the Idaho Mining Association, this subject being discussed at the meeting held on August 22. A number of homestead entries have been recorded in the past few months and several of the cases are in court. The mining men claim that the lumber interests are behind the homesteaders in an endeavor to secure the logs from Pine creek. One of the recent homesteads covers the entire Hilarity group of claims, while the Constitution claims are included in a homestead filing now before the Land Office.

SHOSHONE COUNTY

The Federal Mining & Smelting Co. filed suit against the Headlight company on August 23. The Federal company alleges that it is the owner of the Mammoth and Tariff lodes in Lalande mining district and that the Headlight company claims to be the owner of the Headlight, Grey Eagle, Maggie, Ophir Fraction, and Alexander lodes, situated in the near vicinity. The Federal company also alleges in the complaint that the Headlight company, by means of an adit having its portal on the Headlight claim, has driven an adit under and across the Grey Eagle, Maggie, and Ophir Fraction lodes into and through the Cleveland and Cleveland fraction lodes, owned by the Green Hill-Cleveland company, and has wrongfully entered the Mammoth lode and is now wrongfully extracting ore.

The National Copper M. Co. has again sought relief in the district court in its efforts to construct a flume and grade down Deadman gulch to its new concentrator which is now being constructed. This time Wilhelmina Thompson and her son, Einar, appear as the defendants. An agreement was made between the parties for a right-of-way, but the defendants are alleged to have since refused permission for the work to go on. It is necessary to complete the flume within sixty days.

An addition is being made to the Success mill at Nine Mile, which, among other machinery, will house a mag-

MAP SHOWING POWER-LINES OF THE WASHINGTON WATER POWER COMPANY.

netic separator. The process is for the purpose of extracting iron from the finely crushed zinc and lead concentrate, thereby raising the grade of the shipping product, saving freight on worthless material, and avoiding or reducing smelter penalties on the iron. The process is new in the Coeur d'Alene. The Terrible Edith, at Murray, shipped 99 tons of lead and 55 tons of zinc ore in July. It is said that the ore-shoot is 600 ft. long and from 2 to 6 ft. wide in the adit. The workings are situated high up on a hill and transport is difficult. The ore is sorted by hand.

The Hunter company plans the erection of a new 1000-ton capacity milling plant at Mullan to replace the 300-ton plant now in operation. The site for the new mill has been selected just west of the present plant and nearer the town.

The 14-mile transmission line being constructed by the Idaho-Continental Mining Co. from its power-plant at Boundary Creek to the Idaho-Continental mine is about completed, according to A. Klockmann, president of the Company, who has returned from a several days' visit at the property. Work at the power-site and at the mine is

progressing satisfactorily, and there is no question that the buildings will be completed and the equipment ready to operate by Christmas. From 125 to 150 men are employed, and the number will be increased if necessary to insure the completion of the work before bad weather interferes with the work.

MICHIGAN

HOUGHTON COUNTY

(Special Correspondence.)—The strike has been broken but the mines of this district will be months in getting back to normal working conditions. It is slow work. But the fact is apparent that all the time more of the men are returning to their employment. At the present time all of the conglomerate and two of the amygdaloid shafts of the Calumet & Hecla are in operation; these have been so for ten days. Regular 'rock' shipments are made to the stamp-mills at Lake Linden and the full working force is employed on the surface and in the shops at Calumet. The Calumet & Hecla has the situation in hand better than any of its subsidiaries and other properties. The Superior started a week ago, and while there has been every effort made to intimidate the men and to make trouble for those who have returned to work, ore is being shipped regularly. Isle Royale has started No. 2 and 6 shafts. Quincy is operating two shafts, No. 2 and No. 6, and a large force of men is employed in construction work at the new Pontiac engine-house. Champion has been operating two shafts in a limited way for some time, being the first mine to resume operations. In all of these cases the English, Scotch, Irish, and Welsh miners were the first to return to work, while the Scandinavians have been quite as loyal. The Victoria never suspended. The White Pine, also, has been operating two shafts right along, none of the miners at either of these properties having affiliated with the Federation. It is generally understood that neither the Franklin nor the Winona are in any hurry to resume operations, being content to wait until there is no sign of trouble and the labor market is straightened out. There have been doubtful rumors to the effect that the Winona would suspend operations indefinitely. The failure of the strike here can be laid to the crude methods followed by the officials of the Western Federation of Miners.

Houghton, August 28.

Since the above was written there has been some disturbance in the district, but on the whole the promise of resumption of work is satisfactory. It is estimated that the past month's shut-down resulted in a loss of 16,275,000 lb. of copper and \$800,000 in net earnings to the 12 groups of mines in the district.

MISSOURI

ST. FRANCOIS COUNTY

The strike in the lead belt of southwestern Missouri was settled on August 26. The miners agreed to accept a wage increase of 25c. per day. The Western Federation of Miners was not formally recognized in the settlement. The plan of settlement to which both the union men and mine-owners agreed was that submitted by the State Board of Mediation and Arbitration. The plan provides that if any miner feels at any time that he is unjustly treated, he may submit his grievance to the State Board of Arbitration. The mine-owners agree to abide by the decision of the board.

MONTANA

GRANITE COUNTY

The United States Geological Survey has just issued a report by W. H. Emmons and F. C. Calkins describing the geology and ore deposits of the Phillipsburg quadrangle of western Montana, an area which has produced \$50,000,000 in gold and silver. The first discovery of gold in the state is said to have been made in this area. At one time Phillipsburg held a place among the leading gold and silver camps of the country, and it still produces a fair quantity of these metals.

LINCOLN COUNTY

(Special Correspondence.)—The Hazel T. M. Co., operating the Shaughnessy Hill group, is shipping a carload of its

silver-lead ore to the smelter. According to all reports, the outlook for the property is very favorable. At a recent meeting the following officers were elected: George Chandler, of Spokane, president and treasurer; John H. Town, of Libby, vice-president and manager; and John M. Gleason, of Spokane, secretary. Work has not yet started on the building of a concentrator, but officials of the Company say that one will be built.

The Faith, Hope & Charly Mining Co. has a crew of men at work on its Bear creek property, 20 miles south of Libby, under E. N. Cory, of Spokane, the owner of the claims. There is an orebody on the property about 10 ft. wide carrying gold, silver, and lead. The upper adit, which was driven about 1000 ft., has been abandoned and a new one started 1000 ft. lower.

H. G. Lougee, of Portland, Oregon, recently visited the Montana Silver-Lead Mining & Milling Co.'s property, 15 miles south of Libby, in which he is largely interested.

Libby, August 17.

NEVADA

CHURCHILL COUNTY

During July the Nevada Hills mill treated 3676 tons of ore averaging \$15.62 per ton, the recovery being \$52,489. Costs totaled \$29,094, leaving a profit of \$23,394. Recovery by concentration was 26.3%, and by cyanidation 65.1%, a total of 91.4%. Departmental costs were: mining, \$3.52; milling, \$2.97; marketing, 74c.; taxes and interest, 10c.; and general, 68c.; a total of \$8.01 per ton, less 10c. per ton for miscellaneous earnings. Depreciation is given as \$20,000, and net resources are valued at \$111,734.

CLARK COUNTY

(Special Correspondence.)—Development work at the Yellow Pine mine has been actively carried on while the mill was idle, and large additional ore reserves have been developed. A continuation of the main orebody has been cut on the No. 6 level, south of a fault that displaced the ore on every level in the mine. At the present time a cross-cut has cut 24 ft. of high-grade mixed lead and zinc ore, and the face of the cross-cut is all in ore. The improvements to the mill have been completed, and it has been in operation since August 20. Regular shipments of 60 tons of carbonate of zinc concentrate and 18 tons of lead-silver concentrate are being made daily.

Good Springs, August 28.

(Special Correspondence.)—While the destruction of the 40-stamp mill at the Quartette mine by fire was a severe blow to Searchlight, the effects will be of a temporary nature only. Hardly had the flames subsided when men were started overhauling the Cyrus Noble plant, and power wires were strung to the main shaft of the Quartette to drive the pumps. Quartette ore will now be hauled to the Cyrus Noble mill for treatment until the completion of the new Quartette mill. At the time of the fire there was about \$8000 worth of bullion on the plates and in the mortar-boxes, and an effort is now being made to recover this. The copper plates are being prepared for shipment to the smelter, and all the ashes in the immediate vicinity of the plates are being sacked and these will be smelted to recover the gold content.

Searchlight, August 28.

LINCOLN COUNTY

(Special Correspondence.)—At the town of Atlanta, 45 miles north of Pioche, the Atlanta Consolidated Gold Mining Co. has just completed the installation of a new surface plant and head-frame, and sinking has been resumed. The plant consists of a 110-hp. boiler, an 8½ by 12-in. Lidgerwood hoist, and a 7 by 8 vertical high-speed engine driving sample-grinding machinery, and a 10-kw. direct-current generator for lighting, pumping, and ventilating. A compressor and machine drills will probably be installed. The orebody is a replacement of the lime on a contact between lime and porphyry-andesite, containing gold and silver of value, and from the width and extent of the mineralization promises to be both large and valuable.

Atlanta, August 23.

MINERAL COUNTY

The Aurora Consolidated Mines Co. is installing, among new electrical apparatus at its mines at Aurora, two 2-ton 250-volt electric mining locomotives, one 450-hp. motor, and 25 smaller motors ranging from 2 to 150 hp., 14-kw. and 50-kw. motor-generator sets, three 500-kva. water-cooled transformers, switchboard panels, and accessories. The order for all the equipment has been placed with the General Electric Company.

NYE COUNTY

The Belmont main shaft is to be sunk from No. 14 to No. 15 level at once. Developments on the Belmont, Favorite, Shaft, and Mizpah Fault veins are highly encouraging. A winze from the 750-ft. level of the Extension mine is opening good ore. B. F. Edwards, vice-president of the West End company, states that the condition of the mine warrants the mill being increased to 200 tons daily capacity. On the 1000-ft. level of the Halifax, the vein is 40 ft. wide of payable ore. Ore production of Tonopah mines during the past week in August was 12,512 tons valued at \$281,950.

STOREY COUNTY

The Mexican Gold & Silver Mining Co. has filed its bullion tax statement for the quarter ended June 30, as follows:

Ore treated, tons	1,581
Gross yield	\$92,640
Mining, transport, and treatment.....	59,252
Bullion tax	1,386

WHITE PINE COUNTY

Underground operations by the Consolidated Copper Mines Co. on the Giroux group have been suspended, and all the employees have been paid off and discharged. It is understood that no more ore will be hoisted by the Company, from the Brooks-Morris group at least, for some time, as the ore required to be shipped to the Steptoe plant at McGill under the terms of the treatment contract can be supplied from the Ora claim for the present.

Three steam-shovels and a number of donkey engines have been shipped to Ely for the Copper Mines company, and are expected to arrive soon. Meanwhile the Giroux ore from the Ora claim will be mined by one of the Nevada Consolidated shovels.

NEW MEXICO

SOCORRO COUNTY

The main shaft of the Ernestine Mining Co. has reached a depth of 150 ft. below the old workings. Levels are being driven at regular intervals to intersect the good orebodies opened in the upper zones. The Deadwood mill, the pioneer custom-ore treatment plant in this district, is receiving a large tonnage from development companies in addition to that from its own mine.

The clean-up of the Socorro Mining & Milling Co. for the first half of August produced 18 bars of gold and silver bullion and several tons of high-grade concentrate. The faces on the 800 and 900-ft. levels are reported to be in good ore. The Maud Mining Co.'s new shaft has reached a depth of a little over 500 ft. Good ore is being mined and sent to one of the custom mills. Development work in East End Tunnel Group of the Oaks Co. is producing some good ore, which is being treated at one of the local plants.

SOUTH DAKOTA

LAWRENCE COUNTY

(Special Correspondence.)—Connections have been made between workings from the DeSmet shaft of the Homestake and the deep shaft of the Columbus, which was recently acquired by the Homestake. The DeSmet is the most northerly shaft of the Homestake. Prior to breaking through, the Columbus shaft was drained by skips and pumps. It is understood that this work is largely of an exploratory nature, and upon the results of development work to be undertaken at once will depend the future operations.

Among recent changes at the Trojan mill has been the installation of an Ingersoll-Rand single-stage compressor,

with cylinder 10 by 14½ in., belted direct to a 30-hp. motor. This machine furnishes air for agitation of slime at a pressure of 22 lb. The superintendent, Mr. Ellis, hopes to reduce this below 20 lb., and thus effect a saving in power consumption. The old compressor, which was a smaller machine, was removed to the blacksmith-shop, where a Leyner drill-sharpener and Leyner drill-temperer have recently been added to the equipment. Grading is

HIGHLAND HOIST, HOMESTAKE MINE.

completed for the new addition to the mill which will house thickeners, solution-storage tanks, and a tube-mill, as well as some additional agitation vats.

Deadwood, August 26.

UTAH

SALT LAKE COUNTY

The Alta Consolidated company for some time has been driving toward the contact in which is expected the best orebodies occur. It was while investigating the surface showings along the contact, a few days ago, that A. O. Jacobson, the superintendent, discovered some old workings which may prove valuable. Investigation showed that this old work had been done on the contact and the early operators had abandoned the work after opening what has all the appearance of being an important orebody. Four feet of shipping-grade ore has been opened so far. An average sample of the four feet assayed 1.6% copper, 4.2% lead, 41.4 oz. silver, and \$1.60 gold, while it contains a high percentage of iron.

TOOELE COUNTY

B. L. Cutler, A. M. Perkins, and J. E. Yenny have obtained a two-year bond and lease on the Carrie Mack property, 16 miles from Wendover, and active work has been started. The Carrie Mack is one of the old producers of this state, its output running in the past as high as 888 oz. silver and 64.5% lead. Mr. Cutler and associates believe that they will have the mine back in the production column within a short time.

CANADA

BRITISH COLUMBIA

During July the Nickel Plate mine produced bullion worth \$65,653, making a total to date of \$5,104,373.

ONTARIO

The Buffalo Mines, Ltd., reports as follows for July:

Ore treated, tons	6389
Average assay-value per ton, ounces.....	37.30
Silver recovered, ounces	202,996

During July the McKinley-Darragh-Savage Mines Co. treated 224 tons of ore per day, yielding 224,628 oz. Veins No. 40 and 42 have been opened on the 150-ft. level and show high-grade ore. Equipment to drain Kerr lake is practically complete, and the pumps should soon be at work.

At the McEnaney mine, Porcupine, the drift on the 100-ft. level for 23 ft. opened 6½ ft. of ore averaging \$130 per ton. The August mill return is expected to be about \$50,000.

Mining at the Alexo nickel ore mines, at Iroquois Falls, is being done by open-cutting. At the bottom of the shaft is 4 ft. of ore which averages about 8% nickel, while on one side of the vein there is 3% ore. The August output will be about equal to that of July, namely, 800 tons of ore.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

R. D. GEORGE is at Jackson, California.

CHARLES S. HERZIG, of London, is at Butte.

JAMES DOUGLAS has returned from Europe.

R. E. CRANSTON has returned from Colombia.

ROBERT LINTON was in San Francisco Tuesday.

B. B. THAYER has returned to New York from Butte.

L. G. HUNTLEY returned to Pittsburgh from Alberta.

S. SEVERIN SORESENSEN was in San Francisco this week.

GEORGE MOORE has returned to New York from Colorado.

W. B. RUOGLES is visiting the iron ranges of Minnesota.

KIRBY THOMAS has returned to New York from Wyoming.

C. E. HEALD, JR., is now in charge of Heald's School of Mines.

HOWARD D. SMITH has returned from a short trip to Juneau.

E. A. CAPPELEN SMITH has returned from a holiday in Europe.

HARLAN H. BRADT will be at Columbia University during the winter.

P. R. BRADLEY and EDMUND JUESSEN have been to Calaveras county.

J. MORGAN CLEMENTS passed through San Francisco on his way from Oregon to Los Angeles.

JOHN D. RYAN, president of the Amalgamated Copper Co., is making one of his periodical visits to Butte.

F. P. MILLS, formerly manager of the Giroux Copper Co., has resigned and is spending a holiday in California.

KARL EILERS, who is inspecting the plants of the American Smelting & Refining Co., in the West, was in San Francisco last week.

DONALD FERGUSON returned to Goldfield from Central America, but sailed for London and Paris on the *Lusitania* September 3.

L. D. RICKETTS and JOHN GAENWAY will leave about the middle of September for a trip to inspect the Black Sea copper properties.

MAX W. ATWATER, formerly superintendent of the Butte & Superior, is to succeed Al Frank as manager for the Ohio Copper Co. at Bingham.

WILLET G. MILLER was given the honorary degree of LL.D. at a special convocation of the University of Toronto, held following the International Geological Congress.

PAUL WEISS, director of the Bureau of Mines, of France, who has been attending the International Geological Congress at Toronto, is returning to Paris by way of Montreal.

RICHARD M. EDWARDS, president of the Corbin Copper Co., is in Montana on a tour of inspection of the Company's interests. He is accompanied by Sidney Jennings, of Salt Lake City.

The Old Frelbergers in America will hold the complimentary dinner in honor of RICHARD BECK at the Engineers' Club in New York on September 9, instead of at Scranton, as announced in our issue of August 23.

GEORGE H. GARREY, chief geologist of the American Smelting & Refining Co., and W. H. GRANT, E. K. SOPER, F. C. CALKINS, and J. E. THOMAS, who have been associated with him on examination work, recently returned from Mexico.

J. W. DONALDSON AIKEN has severed his connection as consulting engineer for several Burma companies, and is on his way to Los Angeles by way of London. At Los Angeles, after September 30, his address will be: care Col. W. C. Moss, Huntington Park.

WILLIAM S. MANN, metallurgist for the New York & Honduras Rosario Mining Co., San Juancito, Honduras, has accepted the position of general superintendent for the Socorro Mines, Ltd., Valle de Las Angeles, Honduras, C. A., and expects to take up his new duties on August 1.

New York Metal Market Review

As a result of labor troubles in the Lake district mines, copper advanced steadily in August. Early in the month buying was heavy, but it became less active as the month wore on. Lead moved upward also, as a result of the strike in Missouri; but, bad as the outlook was, buying was not all that might have been expected. Spelter advanced steadily, but throughout most of the month was dull. Antimony was quiet from first to last and prices underwent little change. Tin movements were unusually small, with fairly heavy buying at intervals. Aluminum presented little of interest, with activity lacking and the change in prices showing a decline.

COPPER

At the beginning of August, Lake was quoted at 15.37½c. per lb. cash, and electrolytic at 15.12½c. cash. On August 29, Lake was quoted at 16.12½c. cash and electrolytic at 15.87½c. cash, or 16c. 30 days delivered. The latter quotations were strong, but had been preceded by light buying. The upward movement was due to the unsettled condition of labor in the Lake Superior district. The first few days of the month saw little foreign business because of the bank holiday in London which closed the exchanges from August 1 to 5. On August 6 consumers showed interest in the market, then came in strong, and in the ensuing week buying was heavy, mostly on American account, although Europe was active also. The activity caused prices to advance, and, on August 7, 15.75c. cash was quoted for Lake and 15.50c. cash for electrolytic. By the middle of the month Lake reached 16c. and electrolytic touched 15.75c. cash. The heavy buying was attributed to apprehension over the strike situation, and to the sentiment created by the Copper Producers' Association report for July. Lake copper was hard to find throughout the month, several of the agencies finding need for all their stock in taking care of deliveries on contracts. Activity dwindled about the middle of the month, but quotations remained firm. On August 28, when electrolytic advanced to 15.87½c. cash, renewed buying in large volume was expected. Up to August 29 business was light, with the strike at the mines a serious factor more than ever, despite efforts to operate with other than regular employees. The lack of demand in the third quarter of the month brought out some re-sale lots at 15.62½c., but these were soon withdrawn. The exports from August 1 to 29, inclusive, were 32,932 tons. The July exports were 29,096 tons, making a total of 223,232 tons exported in the first seven months of 1913. The July imports were 18,000 tons. The average price paid for copper in the Naugatuck valley in July was 14.75 cents.

LEAD

The lead market was much disturbed by strike troubles, and the situation near the close of August had not cleared. The month opened with quotations at 4.50c. New York and 4.37½c. St. Louis. At the end of the month quotations were 4.75c. to 4.80c. New York. St. Louis was stronger relatively than New York throughout the month. In the second week rumors were heard of the approaching strike in Missouri, while the Mexican situation also tended to influence the situation. The strike was declared August 15, and several refineries were compelled to shut down at once. Some of them withdrew from the market. For a few days prior to and after the declaring of the strike, business was good. On the day the strike became effective the American Smelting & Refining Co. withdrew from the market for a few hours, and then announced an advance from 4.50c. New York to 4.75c. New York. At this time it was understood that extremely large quantities could not be had at this figure, nor would the Company promise deliveries far into the future. The sentiment of the trade was that the strike meant a long and bitter contest; but, despite this, buying was not greatly stimulated. In the third quarter of the month the large interests were adhering to 4.75c. New York and 4.62½c. St. Louis, but independent brokers made sales at higher prices. August 21, for instance, sales were made at East St. Louis at 4.80c.,

although on August 23 the St. Louis price dropped to 4.70c. because of a mistaken belief that the miners might waive recognition of their union. On August 25 sales were made at 4.80c. New York, and more metal than was available could have been sold at this price. August 29 the big interests had made no further advance.

SPELTER

Business in the early part of the month was reported as fair, though the transactions were not large. Quotations then stood at 5.60c. New York and 5.45c. St. Louis. Prices early showed an advancing tendency which was maintained. With the advances came a somewhat better business. About the middle of the month there was some good buying of high-grade spelter by the brass mills, and this, together with the Western strike troubles and higher prices of ore, accelerated the upward movement in prices. The mid-year statistics of the Government, which became available in the month, explained the slump in spelter in the first half of the year. It appeared that producers' stocks had increased from 4522 tons on January 1 to 21,856 tons on July 1, while consumption had dropped from 181,326 tons in the last half of 1912 to 153,073 tons in the first half of 1913. Production in the first half of 1913 increased slightly. By August 29 prices had advanced to 5.90c. to 5.95c. New York, and 5.75c. to 5.80c. St. Louis. Despite the firmness, the market was quiet on that date.

ANTIMONY

This metal was dull and the net change in August was the loss of a few points only, quotations August 29 being 7.75c. to 8c. for Hallett's, 8.35c. to 8.40c. for Cookson's, and 7.37½c. to 7.50c. for Chinese and Hungarian grades. Inasmuch as all the production is abroad, and large stores are in bonded warehouses, practically all of the buying of futures involved antimony in bond, the buyers expecting the benefit of a lower tariff.

TIN

From August 1 to 27 the fluctuations of tin were unusually narrow, considering the record of the metal for sudden variations in price. On four or five days there was at least fair buying. August 5, about 300 tons were sold in lots for spot delivery, and as far ahead as October and on the following day about 300 tons again were sold for delivery in from 45 to 60 days. On August 26 there was activity in which between 200 and 250 tons changed hands. August 28 and 29, about 400 tons was sold. Sales were made on August 1 at 40.60c., August 6 at 41.50c., August 12 at 41.75c., August 18 at 41.45c., August 26 at 41.95c., August 28 at 43.50c., and August 29 at 42.85c. Arrivals of tin up to and including August 29 were 3634 tons, and there was afloat on that date 1555 tons. July statistics showed that the American consumption of tin in that month amounted to 3900 tons, totaling 27,600 tons since January of this year. This is a decrease of 1800 tons compared with the first seven months of 1912. The total visible supply at the close of July was 12,063 tons, an increase of 962 tons for the month, but a decrease of 1283 tons as compared with July 31, 1912. Deliveries of tin in August were 3600 tons. In stocks and landing at the end of the month was 1408 tons.

ALUMINUM

With aluminum, as with antimony, a feature of the past few weeks has been the large quantity of metal in bonded warehouses awaiting the proposed lower tariff duties. Business could not be called brisk at any time in August, and at times it was called stagnant. Prices for prompt shipments fell off. August 7 quotations were 22.75c. to 23.25c. for domestic and 18.50 to 18.75c. for foreign in bond. Twenty days later, domestic was quoted nominally at 21.50 to 22.50c., and foreign in bond at 18.25 to 18.50c. Toward the end of the month, greater interest was shown in futures, but sellers and buyers were slow in getting together. On August 27 an amendment to place aluminum on the free list was offered in the United States Senate and was referred to the Finance Committee. The House bill proposes a duty of 2c. per pound. Under the circumstances consumers naturally are cautious when dealing in futures.

The Metal Markets

LOCAL METAL PRICES

San Francisco is not a primary market for the common metals except quicksilver. The prices quoted below therefore represent sales of small lots and are not such as an ore producer could expect to realize. Ore contracts usually call for settlement on the basis of Eastern prices, less freight and treatment charges. The prices quoted are in cents per pound, except in the case of quicksilver, which is quoted in dollars per flask of 75 pounds.

San Francisco, September 4.

Antimony.....	12-12½c	Quicksilver (flask).....	
Electrolytic Copper.....	17½-17¾c	Tin.....	46-47½c
Pig Lead.....	5.00-5.95c	Spelter.....	7½-7¾c
Zinc dust, 1400 lb. casks, per 100 lb., small lots	\$9.50-9.75; large		\$7.50-8.50

EASTERN METAL MARKETS

(By wire from New York.)

NEW YORK, September 3.—The copper market is strong and has an upward tendency. Electrolytic copper has advanced ¼c. to 16½c. per pound. The London market is reported as firm, with spot at £72 10s. up 10a.; futures £72, up 11a.6d. All of the producers are asking the equivalent of 16¼c. for electrolytic copper. The lead market remains firm but quiet, quoted at \$4.75. The London quotation is £21, up 2a.6d. The spelter market is quiet but firm. Few sales are reported. The metal is quoted at \$5.80. The London market is reported as quiet and the metal is quoted at £21 12s.6d.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

The mid-monthly report of James Lewia & Sons, Liverpool, dated August 18, includes the following: The improvement in prices is mainly due to a continuance of the strike at the Lake Superior mines; but this is not expected to last much longer. The conclusion of the war in the Balkan states also induced purchases on behalf of both consumers and speculators, considerable sales of manufactured copper being made for India and elsewhere. As a result of enlarged milling equipment shortly expected to be in operation, the quantity of ore treated by the Arizona Copper Co. is expected to be increased from 1500 to 2500 tons per day, representing an increased production of about 11,000 tons of copper per year.

The arrivals in England and France during the fortnight

were 11,061, and the deliveries 11,235 tons. The arrivals here and in Swansea from the United States have been 1460 tons bars, etc., and 812 tons ingots, etc., equal to about 2268 tons fine, in London 75, and in France 2415 tons fine. Arrivals of Chile in Liverpool and Swansea have been 1327 and deliveries 1182 tons, and from other countries 1715 and 1880 tons fine, respectively. The Chile charters for the past fortnight are advised as 1900 tons, including 1125 tons to the United States.

Total European stocks amount to 29,615 tons of copper, while imports since the beginning of the year were 139,512 tons fine.

LEAD

Lead is quoted in cents per pound or dollars per hundred pounds, New York delivery.

QUICKSILVER

The primary market for quicksilver is San Francisco, California, being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

GOLD AND SILVER TRANSACTIONS
NEW YORK
Exports of gold from New York for the week ended August 23, as officially reported at the Custom House, were \$500; of silver, \$664,786, mostly to London. Since January 1 the totals are: gold, \$68,743,196; silver, \$32,216,685; as against \$32,508,133 gold and \$35,651,210 silver for the same time last year. Imports of gold at New York during the week were \$465,224, and silver, \$64,385. Since January 1: gold, \$13,096,286; silver, \$6,375,605; as against \$15,026,315 gold and \$6,324,342 silver for the same period in 1912.

LONDON
During the week ended August 14 about £500,000 arrived in the form of bar gold, of which £183,000 was reserved for India. In the absence of any other external demand of consequence, the bulk of the remainder will be acquired by the Bank of England. The following amounts were received by the Bank: August 7, 8, 11, 12, and 13, bar gold worth £505,000, and the following amounts in sovereigns: from Egypt, £50,000; South America, £525,000; Argentina, £670,000; Uruguay, £252,000; Brazil, £260,000; and France, £5000. Withdrawals in sovereigns were £240,000 for Europe, £50,000 for Peru, and £200,000 for Egypt.

During the week the net influx reached the substantial total of £1,877,000. The net import of gold into India for the month of July was approximately only £234,933.

The tone of the silver market has been steady, and prices have been fairly well maintained, according to Samuel Montagu & Co., writing on August 14. This was only to be expected, considering that both the Indian bazaars and China have been buyers almost daily. The Indian enquiry seems to have set the pace, for the demand for China, though fairly substantial, cannot be called keen, except when the bazaars seemed likely to secure the supplies, which, so far as those from producers were concerned, still continue limited. There is, however, an inclination on the part of Indian speculators to let out some of their stock at, or slightly above, the prices now ruling. An Indian currency return cabled on August 9 showed a decrease in the note circulation of 110 lacs,* and a decrease in the holding of silver rupees of 100 lacs. The period for financing the jute crop has now arrived, and has caused the change in the figures recorded above, for the only method of obtaining silver currency in large amounts is to present notes for payment. This movement from the treasury holding of silver is quite in the natural course of events. Last year the return of August 17 showed a decrease of 110 lacs for a similar reason, and, no doubt, as in previous years, a considerable portion of the silver coin required to finance this crop will return to the treasuries at a later date.

*A lac is a Hindu term equal to 100,000 rupees. One rupee equals 32 cents.

Current Prices for Ores and Minerals

(Corrected monthly by Atkins, Kroll & Co.)

The prices are approximate, subject to fluctuation, and to variation according to quantity, quality, and delivery required. They are quoted, except as noted, f.o.b. San Francisco. Buying prices marked *.

Mineral Paint Production

The production of the natural mineral pigments in the United States in 1912, as reported to the U. S. Geological Survey, amounted to 74,657 short tons, valued at \$561,693. Compared with 1911, this was an increase of 11,918 short tons, or slightly less than 19%; the increase in value was \$62,872, or about 12.6%. The increase in quantity was shared by all the natural pigments enumerated in the table below, except umber and sienna. The production was as follows:

Pigment.	Short tons.	Value.
Ochre	15,269	\$149,289
Umbre and sienna	805	21,975
Metallic paint	28,347	181,352
Mortar colors	9,272	87,595
Slate and shale, ground	20,964	121,482

The total yield of zinc oxide (80.34% zinc), leaded zinc oxide (6 to 20% lead sulphate), and sublimed white and blue lead, amounted to 106,497 short tons, worth \$9,507,895. The chemically manufactured pigments were as follows:

Pigment.	Short tons.	Value.
Basic carbonate white lead:		
In oil	120,591	\$16,041,100
Dry	26,242	2,642,361
Red lead	21,120	2,571,702
Litharge	29,111	3,194,194
Orange mineral	545	88,245
Lithopone	24,220	1,702,119
Venetian red	6,306	116,511

Totals228,135 \$26,356,232
Imports were valued at \$296,031.

Costs of driving the Sunrise adit of the Mountain Top Mining Co., Ouray, Colorado, 7 $\frac{1}{2}$ by 6 $\frac{1}{2}$ ft., a distance of 1974 ft., during the past fiscal year, are as follows:

COST PER FOOT	
Labor:	
Shift bosses	\$1.224
Machine men	2.172
Shovelers	2.785
Blacksmith	0.411
Mechanics, etc.	0.764
Miscellaneous labor.	0.405
Bonus	0.733
Total labor	\$8.494
Supplies:	
Power and light	\$1.136
Explosives	2.945
Candles	0.081
Track, complete	0.324
Ventilating pipes	0.577
Drill parts	0.118
Coal	0.127
Steel and tools	0.034
Oil and miscellane-ous, underground and surface	0.137
Total supplies	\$5.479
Superintendence	\$0.805
Sundries	0.177
Indirect costs	\$0.982
Total cost at mine	\$14.950
Overhead charges, including management, office, taxes, etc.	1.556
Total cost per foot	\$16.512

Decisions Relating to Mining

Specially reported for the MINING AND SCIENTIFIC PRESS.

GAS LEASE—"DOMESTIC PURPOSE" CLAUSE CONSTRUED

A gas lease providing for the furnishing of gas free to the lessor for domestic purposes was held not to entitle him to gas sufficient to operate a large flambeau light in the open air in front of his residence.

Hall v. Philadelphia Co. (West Virginia), 78 South-eastern, 755. May 27, 1913.

DRILLING FOR OIL NOT MINING

Drilling a well in search of oil or gas is not mining within a constitutional provision abrogating the common-law 'fellow servant' doctrine in cases of injuries to employees of mining companies.

Kreps v. Brady (Oklahoma), 133 Pacific, 216. June 24, 1912.

PROCEDURE TO OBTAIN PATENT VERIFICATIONS

The verification of an application for patent to a mining claim by an attorney-in-fact for the claimant, at a time when the claimant himself is both resident and physically within the land district, is unauthorized and entry allowed upon such application invalid.

C. C. Drescher, 41 Land Decisions, 614. March 7, 1913.

MORTGAGEE IN POSSESSION MAY WORK MINE

Where mining property is mortgaged to secure bonds issued by the corporation owning it, both the corporation and its lessees have the right to work the mine reasonably and properly, even though this results in its exhaustion; the rights of the parties being similar to those of a life tenant and reversioner.

Young v. Haviland (Massachusetts), 102 N. E., 338. May 24, 1913.

ADVERSE POSSESSION—REQUIREMENTS FOR PATENT

It is not necessary to entitle a mining claimant to patent under section 2322, Revised Statutes, that such claimant shall personally have been in adverse possession of the claim for the period fixed by that section; it is sufficient thereunder that the claimant and his grantors shall have held and worked the claim for such period.

Paul B. Warnekros, 41 Land Decisions, 653. March 15, 1913.

PUMICE DEPOSITS—LOCATABLE

Land of little value for agricultural purposes, but which contains extensive deposits of finely divided pumice or volcanic ash, suitable for use in the manufacture of roofing materials and abrasive soaps, and having a positive commercial value for such purposes, is mineral land and not subject to disposition under the agricultural laws.

Bennett et al. v. Moll, 41 Land Decisions, 584. December 19, 1912. Rehearing denied April 22, 1913.

MINE-OWNER'S NEGLIGENCE—DEFENSE ABROGATED

A statute which provides that the defense of 'assumption of risk' and 'contributory negligence' shall not be available to a mine owner who has failed to comply with the safety-appliance and inspection laws, is a suit brought by the widow of an employee who was killed in an accident resulting from such lack of precaution on the mine owner's part, has been held constitutional.

Burgin v. Missouri K. & T. Ry. Co. (Kansas), 133 Pacific, 560. July 5, 1913.

PLACER CLAIMANT CONTESTING HOMESTEAD ENTRY

Upon contest of a homestead entry by a placer applicant, if the affidavit of contest contains averments sufficient to apprise the homestead claimant of the nature of the case and to enable him to prepare his defense without danger of surprise, it is immaterial that the affidavit does not contain charges as to the mineral character of each ten-acre subdivision, based upon personal knowledge; but upon trial of the case it will be incumbent upon the mineral claimant

to establish the actual discovery or disclosure of mineral upon each location involved, and that the area in conflict is prima facie mineral in character, containing placer deposits; the contest may then be sustained as to such ten-acre subdivisions as are shown to be mineral in character.

Crystal Marble Quarries Co. v. Dantice, 41 Land Decisions, 642. March 14, 1913.

OIL LEASE INVALID WITHOUT CONSENT OF CO-TENANT

A land-owner by deed granted a one-fourth undivided interest in and to the oil and gas under the surface, and subsequently executed an oil lease to other parties, who went into possession and drilled four wells. It was held, upon suit of the owner of the one-fourth interest for an injunction and accounting, that the owner could confer no rights upon the lessee without consent of the person whom by deed he had made his co-tenant. Injunction against the lessee and accounting granted.

South Penn. Oil Co. v. Hought (West Virginia), 78 Southeastern, 759. February 4, 1913.

COAL LEASE WORKS SEVERANCE—TAXES

A lease of "all the merchantable anthracite coal in, upon or under" certain described tracts constituted a sale of the coal in place, and operated as a severance of the same from the surface, thereby creating a divided ownership between the surface and the minerals. In the absence of any express covenant, the lessee is liable for the taxes on the coal, and if the lessor pays them under protest he may recover the amount thereof in an action against the lessee. He cannot recover, however, such taxes as he may have paid voluntarily under a mistaken belief as to his liability.

Millard v. Delaware L. & W. R. Co. (Pennsylvania), 87 Atlantic, 601. March 31, 1913.

OIL AND GAS LEASE—GENERAL EFFECT OF

Oil and gas, until severed from the realty, are as much a part of it as coal or stone. So long as they remain in the ground, outside of an artificial receptacle at least, as the casing of a well or pipe-line, they must be treated as a part of the realty underneath the surface where they lie. The owner of the surface is the owner of the oil and gas beneath it, but, if they escape into the land of another he ceases to be the owner of them. Where a lessee contracted with plaintiff for the lease of certain oil lands and afterward paid royalties to certain intervenors who claimed under a mineral locator of the lands, the lessees are not estopped, in a suit by the original lessor for rent, to attack the lessor's title. They were, however, denied relief on a counter-claim for the amount of initial payment to the lessor, as an oil lease does not covenant that oil and gas will be delivered, but merely that the lessee may enter, prospect for, and remove the same. An oil and gas lease is construed most strongly against the lessee and in favor of the lessor.

Rives v. Gulf Refining Co., (Louisiana), 62 Southern, 623. May 26, 1913.

MINING CONTRACT—HELD NOT TO BE OPTION

A contract for the sale of certain mining claims provided that the first party agreed to sell and the second parties agreed to buy claims described in the agreement. Total purchase price was to be \$30,000, of which \$25,000 was to be paid as royalties from the output of the mines. No time was set for the commencement or prosecution of work. The second party did not go into possession, it was alleged, nor work the properties. Suit was brought for the total purchase price after lapse of a reasonable time. The court held that this was a binding agreement, not an option; that the fact that the contract called for royalties did not affect its nature as a contract of sale; that it was implied that the claims sold contained minerals, and if they did not, the burden was on the purchaser to prove it as a defense; that it was understood that work must be commenced within a reasonable time by the purchaser.

Pritchard v. McLeod (Alaska), 2051 Federal, 24. May 5, 1913.

Company Reports

GREAT BOULDER PROPRIETARY GOLD MINES, LTD.

This Company owns 85 acres in the heart of the 'Golden Mile,' Kalgoorlie, Western Australia, and from 1895 to 1912, inclusive, has produced 2,401,419 tons of ore valued at \$43,000,000, and paid \$19,000,000 in dividends. The report, which consists of 38 pages and 13 plans of the mine, is of the usual excellent character of many English mining companies, and from the remarks of the general manager, Richard Hamilton, the following is abstracted.

There are three main shafts in this property, the Main 2844 ft., Edwards 2879 ft., and Hamilton 1978 ft. deep, all of which are equipped with hoists for handling ore and men. Development for the year was 2419, making a total of 110,487 ft. to date, while diamond-drilling, which has always been a strong feature in prospecting at this mine, amounted to 1252 ft., a total of 48,020 ft. to date. From the report it is shown that drifts, winzes, and cross-cuts have opened ore in over 50 different places, and the following table shows the existing orebodies in reserve at the various levels:

Level.	Length of ore remaining in backs, feet.	Average width, feet.	Average assay value, dwt.
300	285	6.4	6.0
500	173	6.6	30.0
600	175	7.0	8.0
600 (west vein)	145	7.2	9.0
700	480	8.5	21.0
800	265	10.5	34.0
900	459	12.5	32.0
1000	540	11.8	17.0
1100	500	10.1	23.0
1200	475	11.3	18.0
1300	1336	12.2	15.8
1400	1158	11.9	14.0
1500	1270	12.0	12.0
1600	1167	12.3	11.0
1750	1093	12.7	7.4
1900	1510	15.1	10.0
2050	1405	14.4	9.0
2200	1392	15.1	15.4
2350	1290	13.3	9.5
2500	960	10.1	9.8

The grand total of all ore reserves is 652,916 long tons averaging 14.59 dwt. per ton.

At about 2550 ft. the lode passed into the Horse-Shoe property, and that Company has since been developing this deposit partly through connections made with the Boulder mine. Connection has been made at the 2050 and 2500-ft. levels with the Golden Horse-Shoe main shaft. This has materially improved the ventilation in the Boulder mine.

Except the lens of ore found at the 500-ft. level between Edwards and Lane shafts, no fresh orebody has been discovered during the year. Diamond-drill holes have been put down to a depth of 270 ft. below the 1950-ft. level, Hamilton shaft, without finding any sign of ore. Up to the present time 56 bore-holes, averaging a horizontal length of over 300 ft. each, have been driven into the formation east of the main lode and the lode at Hamilton shaft. Many of these holes cover the distance between the lodes and the eastern boundary, and have been put in at various depths below the surface from the 100 to the 2800-ft. level. The horizontal bore to the eastern boundary from the 1800-ft. level, Hamilton shaft, passed through 6 ft. 6 in. of ore worth \$8.50 per ton at 145 ft. from the eastern boundary, and 7 ft. of ore worth \$1.50 at 2 ft. from the boundary. The other holes did not discover any ore worth working.

Bore-holes at the Main and Edwards shafts have reached a depth of 3000 ft. below the surface on the western boundary without finding any ore. When permission is given by the Golden Horse-Shoe company, allowing the Boulder the drill from the former's 2800-ft. level, other bore-holes will be drilled in an easterly direction to test the country underneath the Boulder main ore-shoot, and from the 500-

ft. level between Edwards and Lane shafts more drilling will be done. Prospecting work at the 2650 and 2800-ft. levels has not discovered any profitable ore.

The treatment plant, which consists of crushers, Krupp and Griffin mills, Edwards and Merton roasting furnaces, grinding pans, thickening plant, mechanical agitators, and Ridgway vacuum-filters, dealt with 193,451 tons of ore yielding \$2,726,000. Dividends paid amounted to \$1,258,000. The Company had at December 31, 1912, cash and bullion in transit valued at \$796,000, and reserve fund account of \$168,000.

THE EL PASO CONSOLIDATED GOLD MINING CO.

The Company was incorporated under the laws of Colorado in 1893 and owns gold-mining property on Beacon hill, Cripple Creek, Colorado. The authorized capital is \$2,500,000, in 500,000 shares of \$5 each, all issued and fully paid. The net operating earnings for the year were \$243,429. While this figure covers the earnings of the fiscal year, the production of ore on Company account from the formerly submerged levels, which were made accessible through the drainage of the mine by direct connection with the Roosevelt drainage tunnel, only covered

EL PASO MINE.

a period including the last six months of the year. The total development was 6039 ft., more than a mile of driving through the hardest kind of Pike's Peak granite. The mine has been proved to a depth of 1350 ft. by opening its orebodies from the Roosevelt drainage tunnel. The year 1913 was begun with the mine completely drained. During 1912 dividends to the amount of \$122,500 were paid. The stock owned by this Company in the Cripple Creek Drainage & Tunnel Co. now amounts to \$43,000, and is being amortized at the rate of \$24,000 per year. The Colorado Mines, Railways & Utilities Corporation has been formed, under the laws of Delaware to purchase the Golden Cycle stock held on option. The financial statement of the El Paso G. M. Co. shows that its mining property is valued at \$2,589,112, cash on hand amounts to \$132,056, and the surplus of assets over liabilities is \$492,103. Total earnings for the year were \$849,305, and the net operating earnings were \$238,757. Mining costs were \$186,912, and shipping and selling \$233,022. Four dividends of \$24,500 each were paid during the year.

THE BATOPILAS MINING COMPANY

The Batopilas Mining, Smelting & Refining Co., Ltd., of London, was organized in 1909 to acquire on lease for 25 years the property of the Batopilas Mining Co., of New York. The latter is a consolidation of ten mining companies, the capital is \$9,000,000 in shares of \$20 each, and there are \$1,000,000 6% gold bonds. The Batopilas Mining Co. owns 225,000, or 85% of the shares of the London company. The property comprises silver mines near the town of Batopilas, in the Andres del Rio district, Chihuahua, Mexico. The report for 1912 states that the properties of the Company have been the only mines in that part of Mexico that have not at some time during the past two years suspended operations. The report of Walter M. Brodie, the consulting engineer, gives the total production as 504 bars, or 516,669 oz. Most of this is

from the San Miguel mines. Of the silver produced, about 43% came from the coarse metallic silver in the ore, 17% from the finer metallic silver in the ore, 10% from the tailing of the higher-grade ore, and 30% from the low-grade ores. Some of the veins in the San Miguel group were worked over a hundred years ago, and although there is no ore in sight in the Batopilas mines, the promise for the future can only be calculated from former results. The tonnage of ore for 1912 was: high grade, 812,317.5 tons; low grade, 32,261 tons; a total of 33,073,317.5 tons. The average price realized for bullion was 54.29c. per fine ounce, an increase of $\frac{3}{4}$ c. per ounce over 1911. A deficit of \$17,409 for 1911 was reported, but for the first six months of 1912 there is an estimated profit of over \$25,000. Owing to the disturbed conditions in Mexico, the freighting of supplies and shipping of ore have often been very hazardous, and at times it has seemed as though the plants would have to shut down.

HORN SILVER MINING COMPANY

The Horn Silver Mining Co., of Frisco, Utah, has a capital account of \$10,000,000. The report for 1912 gives details of a cave-in during October, necessitating the expenditure of over \$20,000 for repairs and preventing mining operations and shipments of ore for over two months. The shipments during the year were 6999 dry tons of mine lead ore, 2031 of mine zinc ore, 6334 of tailing, 4483 of slag, and 30 tons of second-class ore, having an average value of \$6.88 per ton. The operating expense averaged \$6.06 per ton, yielding a net profit of \$16,606, or 83.5c. per ton. The ore reserves have been increased during the year. The profit and loss account for the year ended December 31, 1912, is as follows:

Ore mined by Company	\$120,543
Ore mined by lessees	17,031
<hr/>	
Total value	\$137,574
Refunds, interest, store profit.....	13,407
<hr/>	
Total income	\$150,981
Mining, royalty, taxes, smelting, New York expenses, etc.	140,829
<hr/>	
Balance	\$ 10,152

THE TRI-BULLION SMELTING & DEVELOPMENT CO.

The Company owns mines at Kelly, New Mexico, in Graham county, Arizona, and in Jefferson county, Montana, producing lead, zinc, and copper. The capital stock is \$5,034,653, with 1,000,000 shares of common stock and 6930 $\frac{3}{5}$ shares preferred, at a par value of \$5. The gross income from mining for the year was \$319,487; the costs at the mines were \$173,336. There was a net profit in mining of \$71,307. The shipments during 1912 aggregated 14,117 tons, and consisted of 9243 tons of zinc concentrate yielding \$217,718, 2060 tons of lead concentrate yielding \$60,401, 1552 tons of zinc carbonate yielding \$26,855, 965 tons of iron middling yielding \$598, 31 tons of zinc sulphate yielding \$842, and 266 tons of copper ore yielding \$1544. In addition, \$1425 worth of copper ore has been mined and is ready for shipment and ore worth \$40,917 is in transit. Expenditures on mining were \$70,178, and on milling \$83,390. Apparently only the properties at Kelly, New Mexico, are being operated. During the year the Silver Bell and the Nit group of claims have been acquired. Development on these was so satisfactory that a rope tramway is in process of construction for the transport of these ores to the mill.

CORBIN COPPER COMPANY

This Company was organized in 1903 under the mining laws of Michigan. The capital stock is \$3,750,000, in 150,000 shares of \$25 each, and 130,000 shares have been issued. The Company owns 57 mining claims in Jefferson county, Montana, and is exploring under lease and bond nine claims at Rochester, Madison county, Montana. It also has an option to purchase three mining claims in Butte, the Gambrinus, Belcher, and Welch. Development work

has been done from the Bonanza adit, and 7740 cu. ft. of ore was stoped above the adit level and milled, netting \$1249, and five cars of ore were produced from the Rosalie adit, netting \$1571. The ore contains gold and copper. The year 1912 closed with a deficit of \$62,502. At Rochester, a steam hoist capable of sinking 500 ft. has been erected, the shaft has been re-timbered from the 200-ft. level down to 230 ft., and the shaft sunk to the 300-ft. level. A cross-cut is also being driven north on the 225-ft. level. At Glenbeg, nine claims were located and the necessary assessment work done. In the Warm Springs district, \$2000 was expended on a group of five claims.

MT. MORGAN GOLD MINING COMPANY, LTD.

This Company operates a well known property in Queensland, Australia, and the report of the general manager, B. Magnus, covers the year ended May 31, 1913.

Development in the Mt. Morgan mine covered 660 ft. from the 317 to 1050-ft. level. Eight diamond-drill holes were completed in the year, making a total of 3413 ft. On the 850-ft. level, hole No. 45, going horizontally in a southwesterly direction from the south end of No. 10 cross-cut, at 565 ft. went through 40 ft. of ore suitable for concentrating. Another drill-hole is now in progress to cut this body at a point 200 ft. above and 80 ft. to the northwest. As it will be many years before it will be necessary to mine what ore is found there, it is not the intention to do much more work on this at present.

The preparatory work in the mine to open it for the supply of concentrating ore is now in progress, and it is expected that early next year the mine will be able to supply an additional 600 to 700 tons per working day.

A reestimation of those blocks of ore which are not taken into account in the published reserves, because they are either too highly silicious or too low in metal value for profitable smelting, has been made. From these figures, the quantity which can be profitably handled as a concentrating ore is such that, to exhaust it and the smelting ore simultaneously, we will require to treat a minimum of 500 tons of concentrating ore per day. With the concentrator running and the exact data available to base calculations upon, the Company will then be in a position to take into account the published reserves this quantity of ore, which until now has been omitted therefrom, as being unprofitable under present treatment conditions. Ore reserves amount to 1,365,000 tons of high and 1,982,000 tons of medium-grade ore.

At the Many Peaks property, which supplies copper-bearing pyrite for the smelter, development covered 1469 ft. In the central working on the 570-ft. level, the westerly cross-cut has proved a width of 90 ft. of ore, and a northerly drift, a length of 75 ft., the face of this last being still in ore. Twenty-five per cent in volume of this body is waste material.

At the Mannor limestone quarries, 99,022 tons was mined, of which 78,621 tons was used as flux and the rest sold. A modern lime-burning plant is being installed. The coal property being developed is opening satisfactorily.

The smelter treated a total of 322,098 tons of ore and miscellaneous products, yielding 9280 tons of copper and 118,488 oz. gold. Many improvements were made to the existing plant. Specially lined converters were installed, but the present power-plant is not capable of supplying sufficient air, in fact it has given considerable trouble during the year.

Results of the year's work may be shown as follows:	
Revenue from 9280 tons copper and 126,083 oz. gold	\$5,424,000
Total expenditure	\$3,691,000
Dividends paid	\$960,000
Depreciation	\$115,000
Totals to date:	
Ore chlorinated, tons (plant shut down)....	3,757,263
Ore smelted, tons	1,511,885
Gold from chlorination, ounces.....	3,462,298
Gold from smelters, ounces	591,410
Copper production, tons.....	43,207
Total revenue	\$91,872,000
Dividends	\$39,000,000

Concentrates

HEATING SOLUTIONS has not proved advantageous at the Waihi mills, New Zealand, where the ore contains about \$8 gold and $3\frac{1}{2}$ oz. silver per ton.

A HOISTING ACCIDENT at the Mysore mine, India, on August 22, resulted in the death of 50 miners (probably native) when a cage dropped to the bottom of a shaft.

MILLS in South Dakota during 1912 consumed 14,095 lb. of quicksilver, 139,657 lb. of potassium cyanide, and 439,974 lb. of sodium cyanide in the treatment of 1,893,836 tons of ore.

ARMOR PLATE is to be made by the Carbon Steel Co., of Pittsburgh, for the United States Government. The contract is for 3900 tons at \$187.04 per ton, a reduction of \$96.99 on the last contract.

LOCKS at the Panama canal have useful dimensions of 1000 by 110 ft. by 40 to $41\frac{1}{2}$ ft., while those of the Kaiser Wilhelm canal, Germany, are 1082.6 by 147.6 ft. by 45.1 ft. The respective length of each canal is 45 and 61.3 miles.

FROM THE TREATMENT OF PITCHBLEND at St. Joachimsthal, 2.2 gm. of radium was recovered, valued at \$196,504, by the Austrian Government in 1912. In 1911 the production was 2.6 gm., valued at \$211,120. None was shipped from this district to the United States. Uranium and uranium colors are also being produced in increasing quantities at St. Joachimsthal, in conjunction with radium.

TO PROTECT the many miners working in the coal mines, the last Oklahoma legislature passed a law requiring all such mines to install telephones. They are to be placed every 1000 ft. in the mines and connected to the surface. By this arrangement there will never be a man over 500 ft. from a telephone, which, in case of an accident or explosion, will make it possible to get in communication with the surface almost instantly.

TRANSPORT of ore and concentrate from the Ben Harrison mine, Oregon, to the railroad at Whitney, a distance of 21 miles, costs \$8 per ton by wagon haul. To reduce this expense, a gasoline tractor of the caterpillar type has been ordered. It is a six-cylinder, 100-hp. machine, running at from 2 to 6 miles per hour. The tractor will carry 5 tons, and two trailers 10 tons each. To deal with snow in the winter, a snowplow will be attached to clear the road.

THE total annual consumption of oil for fuel, including that used in the manufacture of gas, in California, is between 50,000,000 and 55,000,000 barrels, equivalent to approximately 1,500,000 tons of coal, or about twice as much as the coal consumed within the state. The total consumption of coal in 1912, estimated from the rail and water receipts, was about 770,000 short tons. Less than 500,000 tons of coal was consumed in the vicinity of San Francisco.

MAGNETITE beds occurring in sandstone formation have been discovered in the Blackfoot Indian Reservation, in northwestern Montana, by Eugene Stebinger of the United States Geological Survey. The mineral averages 27.3% iron and 8.3% titanium oxide near the Croff ranch, and on the other side of the Milk river, 33.2% iron and 10.6% titanium oxide. This high titanium content renders these ores unfit for use, according to present metallurgical practice, although it is believed that ores of this type may eventually be successfully smelted.

ORE at the Ophir mill, Virginia City, Nevada, is now being treated direct by cyanidation without previous concentration. This method seems to give good results, provided the ore is given a sufficiently long treatment, but the result of a longer treatment is, of course, a reduction of the capacity of the plant. The cost of marketing con-

centrate ranges from 80c. to \$1.50 per ton of ore treated, according to the grade of ore and concentrate. The superintendent, Walter Techow, is inclined to think that the most economical process is a part reduction of the original value of the ore by concentration, removing about 40 to 50% and leaving the rest for the cyanide plant.

CAPITAL invested or to be invested in hydro-electric power in Japan is as follows:

	Yen.*
Local prefectures	417,688
Cities	87,684,687
Towns	369,120
Private	412,055
Companies	373,236,377

Total 462,119,927

*One yen = 49.8 cents.

The power to be obtained is estimated at 778,231 kilowatts.

HOISTING ENGINES situated at and below horizon No. 8 in the Morro Velho mine, Brazil, are to be driven by electricity instead of compressed air. It is estimated that the saving in power by this change would be sufficient to drive machine-drills for the whole of the rock drilling, thus saving a number of hand-drills. With regard to drilling, actual experience at this mine has shown in the case of the machine-drill on a bar, one man does the work of five hand-drillers, and with the telescope hammer-drill one man does the same work as $4\frac{1}{4}$ hand-drillers. The actual saving in cost is 2.38 and 18.02c. per foot drilled, respectively, but in the rock broken, the comparison becomes much more favorable for the large machine-drill on bar, on account of the larger and deeper hole, and heavier charge of explosive it will take.

RADIUM is a metallic element that is transmuted at a much more rapid rate than is uranium. Considering equal weights of uranium and radium element, in a year 0.00000000014 of the total quantity of the uranium and 0.00035 of the total quantity of radium will decay. The ratio of the quantity of radium to the quantity of uranium decaying is 2,500,000. From this it may be seen that for equal weights of the two elements there will be enormously more rays from the radium than from the uranium, since a larger proportion of all the radium atoms undergo a transmutation in any given interval of time. Radium bromide ($\text{RaBr}_2 \cdot 2\text{H}_2\text{O}$) contains 53.6% of radium element; radium chloride (RaCl_2) contains 76.1%; radium sulphate (RaSO_4) contains 70.2%; and radium carbonate (RaCO_3) contains 79 per cent.

METHODS for the prevention of the tremendous waste that usually accompanies the 'coming in' of wells producing large quantities of oil or gas by natural flow fall naturally into two classes, preventive and remedial. The first has to do with keeping under control whatever gas or oil may be encountered in the process of drilling; the second relates to the capping or subduing of wells 'blown out' or 'gone wild,' according to Ralph Arnold and V. R. Garfield of the Bureau of Mines. It is interesting to note the following general conditions affecting flowing gas and oil wells in California, for they have an important bearing on the success of either class of operations: (1) The gas from 'gassers' and the gas that generally accompanies the oil is not injurious to health, hence workmen without being harmed may labor near the well; (2) owing to the tremendous velocity of the stream of gas, the part immediately over the casing head is like a smooth column, and may be approached with safety; (3) the sand usually expelled under tremendous force with the oil or gas often wears out the casings, but this wearing action generally takes place only throughout the uppermost 30 or 40 ft. and opposite or near the place where the gas enters the well, thus leaving the main part of the entire length of the strings practically sound; and (4) the great volume and tremendous pressure of the gas and oil make the use of the best fittings a necessity. Some of these, being of special sizes, are made to order.

Mineral Production of North Carolina

During 1912 the North Carolina Geological and Economic Survey continued its coöperation with the United States Geological Survey in the collection of statistics of the production of all the minerals and ores (including clay products) which were mined in North Carolina during that year. These statistics will be published in connection with more elaborate data later in the year. The output was as follows: gold, \$166,014; silver, \$2985; copper, \$10,521; lead and zinc, \$25,694; iron, \$186,264; abrasives, \$10,914; mica, \$256,549; precious stones, \$5655; talc and pyrophyllite, \$63,304; mineral waters, \$24,284; stone, \$1,085,267; sand and gravel, \$19,737; clay products, \$1,605,470; and miscellaneous, \$29,929; a total of \$3,492,587.

Metal Production of Wyoming

The total value of the production of gold, silver, and copper in the state of Wyoming in 1912 was \$26,947, a decrease of \$7460 from that of 1911, according to Charles W. Henderson of the United States Geological Survey. The gold yield increased somewhat, but the output of copper and silver decreased. There were 17 producing mines, of which 8 were lode and 9 were placer.

The quantity of ore sold or treated was 2439 short tons, as compared with 3491 tons in 1911. The output of silicious ore increased from 1447 tons in 1911 to 2284 tons in 1912, but that of copper ore decreased from 2044 tons in 1911 to 155 tons. Lode mines yielded \$21,469 in gold, 263 fine ounces of silver, and 27,570 lb. of copper. Placer gold production amounted to \$766 in 1912, as compared with \$7041 in 1911. The copper yield, usually of chief importance in this state, represented only 17% of the state's total in 1912, gold representing 82.5% of the value. Since 1867 the total value of all metals was \$5,294,434.

Coal Mining in Pennsylvania

The combined production of anthracite and bituminous coal in Pennsylvania amounted in 1912 to 246,227,086 short tons, valued at \$346,993,123, against 235,218,230 tons, valued at \$321,537,250, in 1911, according to E. W. Parker, of the U. S. Geological Survey, who compiled the figures in coöperation with the State Topographic and Geologic Survey Commission. The increase in quantity was 11,008,856 short tons, or 4.7%, and the gain in value \$25,455,873, or 7.9%. In 1911 the larger percentage of increase in value was due to an increase in the production of anthracite and a decrease in the output of the lower-priced soft coal. The total quantity of bituminous coal produced in the state in 1912 was 161,865,488 short tons, valued at \$169,370,497, and that of anthracite coal 84,361,598 short tons, valued at \$177,622,626. In 1912 both anthracite and bituminous values were increased in larger ratio than the increase in tonnage. On account of the suspension of operations on April 1 the production of anthracite in 1912 was less than in 1911 by 5,448,633 long tons in quantity and by \$2,670,021 in value. The production of bituminous coal, on the other hand, increased 17,304,231 short tons in quantity and \$23,215,545 in value. The average value per ton increased for both grades, anthracite from \$2.17 to \$2.36 per long ton and bituminous coal from \$1.01 to \$1.05 per short ton. The production of bituminous coal in Pennsylvania in 1912 exceeded that of anthracite by 77,503,890 short tons, or 93%, but the value of the latter exceeded that of the former by \$8,252,129.

A somewhat unusual comparison is presented in the statistics covering the labor employed in the anthracite and bituminous coal mines of Pennsylvania in 1912. Notwithstanding the decrease in the production of anthracite, more men were employed in the anthracite mines in 1912 than in 1911, whereas in the bituminous mines the production showed a material increase with fewer employees. The number of men employed in the anthracite mines in 1912 was 174,020, against 172,585 in 1911. The bituminous workers numbered 165,144 in 1912 and 168,199 in 1911.

The average number of working days in the anthracite region, however, decreased from 246 in 1911 to 231 in 1912, while in the bituminous mines the average working time increased from 233 days in 1911 to 252 days in 1912. The average yearly production per man in the anthracite region in 1912 was 434 long or 486 short tons, and in the bituminous fields 980 short tons. The total number of men employed in the coal mines of Pennsylvania in 1912 was 339,174, against 340,859 in 1911.

Metal Production of South Dakota

The total value of the production of gold, silver, and lead in South Dakota for 1912, as reported from 40 productive mines, 19 of which were placers, amounted to \$8,019,371, according to Charles W. Henderson of the United States Geological Survey. This is the largest production in any one year, the output being \$229,183 above the previous maximum mine yield of \$7,790,188 in 1908 and \$468,613 larger than that of 1911. The gold output was 381,745.02 fine oz., valued at \$7,891,370, over 98% of the total value. The increase in gold yield for the year was 21,841.12 fine oz. in quantity and \$451,496 in value. The production of silver also increased from 203,755 to 206,460 fine oz. Smelting ore from South Dakota in 1912 contained 22,845 lb. of lead, against 64,311 lb. in 1911. Placer gold increased from 584.03 fine oz. in 1911 to 663.95 oz. in 1912. Some of the placer gold was sold for use in the arts.

The total quantity of ore mined and treated in 1912 was 1,901,726 short tons, averaging 0.20 oz., or \$4.14 in gold, as compared with 1,946,127 short tons, averaging \$3.817 in 1911, and with 1,523,929 short tons averaging \$3.543 in 1910. There were 1,893,836 tons treated in the mills of the state, yielding as bullion \$7,734,806 in gold and 179,335 fine oz. of silver, valued at \$110,291, a total value of \$7,845,097, or an average recovery per ton of \$4.08 in gold and of \$0.058 in silver, as compared with \$3.77 in gold and \$0.05 in silver in 1911. The quantity of crude ore shipped to smelters amounted to 7890 tons, having an average content in gold of 0.8758 oz., or \$18.10 per ton, and of 3.43 oz. in silver. The production by counties was as follows:

	Custer.	Lawrence.	Pennington.
Mines producing	5	19	16
Tonnage	75	1,901,310	341
Gold	\$1187	\$7,875,401	\$14,782
Silver, ounces	3	206,356	101
Lead, pounds		22,845
Total value of metals.....	\$1189	\$8,003,338	\$14,844

Total production of gold and silver in South Dakota from 1876 to 1912, inclusive, was \$170,634,838 and \$4,011,679, respectively.

Pottery Production

The value of the pottery products of the United States in 1912 was \$36,504,164, the largest yet reported, exceeding that of 1911 by \$1,985,604, or 5.75%, and that of 1910 by \$2,719,486, or 8.05%. Only one variety decreased in value in 1912—stoneware—which declined \$200,830, or 4.87%. With the exception of stoneware, every product reached its maximum in 1912, the variety showing the largest gain being sanitary ware, which increased \$870,797, or 12.38%. The largest proportional gain was in porcelain electrical supplies, which increased \$695,215, or 16.43 per cent.

The value of white ware, including china, but excluding sanitary ware and porcelain electrical supplies, was \$17,006,736 in 1912, as compared with \$16,424,236 in 1911, an increase of \$582,500, or 3.55%. These articles constituted 46.58% of all pottery products in 1912, and 47.58% in 1911. If the value of sanitary ware and porcelain electrical supplies be added, the value for 1912 would be \$29,836,307, or 81.73% of all pottery products, an increase of \$2,148,512, or 7.76% over the figures for 1911.

Chinaware showed an increase of \$119,320, or 5.80%. The value reported for 1912 was the highest ever recorded.

PASSAGE of the tariff bill by the Senate will be welcomed even by those opposed to the changes made. The latter have been certain for some time, and there has been no real gain from the prolonged discussion that has waged. Under the new act, the rates on metals will be generally lower and numerous additions are made to the free list. Among these are steel ingots; ferro manganese; wrought iron slabs and blooms; pig iron, cast iron pipe; cement; limestone; antimony ore; rock asphalt, asphaltum, and bitumen; and many others. We have already discussed the probable effect of some of these changes.

ANOTHER mining journal has suspended publication, *Mines and Methods*, a lively little monthly printed at Salt Lake City. We have not often been able to agree with *Mines and Methods*, but we did enjoy reading it, for much real ability went into its editing. The trouble was that it answered no economic need, and was an organ rather than a real technical journal. Success in the field of publication must rest on a bigger and broader basis than a personal quarrel and the desire to criticize, soundly or unsoundly, a particular group of mine promoters. The world rewards liberally those who give service, but it resents being used to further personal fortunes.

AMONG the characteristics of modern development is a constantly increasing use of artificial light, and the preëminence of electric lighting, already buttressed by its convenience and the quality of light afforded, seems to be firmly established by the announcement by two well known German makers of electrical equipment that before the end of this year they will be able to supply incandescent lamps which use only one-half watt per candle-power. The ordinary carbon filament lamp requires three to four watts per candle-power, and the best tungsten lamps about 1¼ watts per candle-power. As a result, we hope, there will be fewer mashed fingers and other injuries in dark places.

A FEW years ago when a boycott of all American products was being urged by some of our disgruntled neighbors on the other side of the Rio Grande, it was discovered that to make the boycott complete, there would have to be substituted some standard of exchange for the much sought 'gringo' made currency, and as a result the boycott enthusiasts were stumped. However, that this will be no handicap in the future is evidenced by the fact that almost every 'rebel' chieftain is at present a self-

constituted bureau of printing and engraving, and home industry banknotes are becoming more plentiful than *tortillas* and *frijolles*. The latest addition to the new-freedom money is reported from Parral, where the 'rebels,' having appropriated a press from the Tecolotes company, are minting a new currency under the supervision of two American soldiers-of-fortune. It is stated that the 'mint officials' are now investigating various properties in the district as a source of bullion and the Palmilla is being looked upon with favor.

DEPARTURE from San Francisco Wednesday of Mr. Francis Burton Harrison, the new Governor General of the Philippines, marks the beginning of an era in the Islands that will be watched with great anxiety at home and abroad. Mr. Harrison is the appointee of an administration pledged to give independence to the Islands. As to this main purpose there is no real or large dissent in the United States, but there are sharp differences of opinion as to when and how the change is to be brought about. Those most familiar with conditions hold stoutly to the belief that real independence could not now be maintained if granted, and many feel that even agitation of the matter is unwise, since by promoting unrest it complicates the situation. The Islands will be given independence at the earliest moment that the people of the United States can be sure the act will prove a blessing rather than a curse to the Filipinos. The danger is that the change may come too soon. The new Governor General is a man of high character, of wide experience, and proved ability. He will have peculiarly difficult decisions to make. We trust that the excellent record already made by officials in the Islands may be maintained and that he may find the right solution for his many difficulties.

MINING engineers as well as geologists have a lively interest in all that relates to ore deposits, and to them there was no session of the recent International Geological Congress that was of more interest than the one devoted to discussion of the various problems of ore deposition. It was notable that the most active participants in the discussion were North Americans, though there were honorable exceptions. In the United States and in Canada the geologist has been coming into his own rapidly these past few years, and nowhere is more study devoted to the problems of mining geology. The excellent work done abroad, however, should not be overlooked, and we take especial pleasure in printing this week the scholarly address read to the Congress by Mr. Paul Krusch, of the mining school at Berlin, one of the leaders of modern research as relates to ore deposits. It will be noted that Mr. Krusch uses the differences between gel and crystalline ores in making discriminations in a way new to us. His pronounced leaning toward the secondary origin of ores is also notable, the more so because in this, after the pioneer work of Mr. L. de Launay, Europeans were a bit slow to follow their American confreres. Next week we will print an extract from the remarkable paper on 'Butte Ore Deposits,' in which Mr. Reno Sales marshals the evidence against

the secondary origin of much of the chalcocite at Butte. In the meantime, Mr. Krusch's paper may be read as an expression of the best continental thought on the general subject.

Canada as an Iron Producer

The rapid growth of the Dominion of Canada as a producer of iron and steel is exhibited in the statistics of output for 1912, which have just been given out. Shipments of iron ore from Canadian mines during 1912 were 192,753 tons, while 1,802,826 tons of imported ore was smelted in Canadian blast-furnaces. The output of steel was 853,031 tons, to which figure it has grown from 26,084 tons in 1902. It is expected that the 1913 output will exceed 1,000,000 tons.

Iron ores are found in many parts of Canada, but only in Nova Scotia, Ontario, and Quebec have they so far proved of economic importance. However, Canada is a rapidly growing country, and many deposits now available are quite likely to be made the basis of profitable industry when conditions shall warrant. As is natural, the deposits first worked occur in the regions which were first settled. The bog iron ores of the lower St. Lawrence near Three Rivers were described as early as 1681, their exploitation began in 1733, and has been continuous to the present day. The rapidity with which these curious deposits form is one of their most remarkable characteristics, some of them being deposited so rapidly as to form practically a continuous supply. Attempts were made to smelt the ores of Ontario in 1800 and 1820, the first successful furnace being at Normandale, where the bog ores of Norfolk county were handled. More recently iron ores have been discovered scattered over the whole pre-Cambrian area of the province. The largest producer is the Helen mine near Michipicoten, where the ore, hematite and limonite in a porous concretionary like slate, associated with a good deal of pyrite, lies in or on a bank of silicious siderite in a closely folded syncline. These ores are regarded as chemical precipitates. Another large producer is the Moose Mountain, Ltd., about 25 miles north of Sudbury, where disseminated magnetite is magnetically concentrated and shipped to the Lake furnaces. There are enormous reserves here and steady progress is being made in solving the peculiarly complex technical and industrial problems that stand in the way of their utilization.

Nova Scotia, though a close second to Ontario in steel production, does not produce much ore; the output in 1907 being less than 90,000 tons. The deposits, though widely scattered and of great variety, are commonly small and can scarcely be made the basis of profitable industry. The coal mines of Nova Scotia, which yield nearly one-third of the total output of Canada, have made it possible to smelt imported ores on a large scale, the output of steel in 1912 having been only 1321 tons less than that of Ontario. The most important plant in Nova Scotia is that of the Dominion Iron & Steel Company, in which Mr. F. S. Pearson was the leading spirit.

Iron ore also occurs in the vicinity of Kootenay

lake and a deposit on the south shore of Kamloops lake has yielded some output. On Texada island, on the west coast, magnetite occurs and has been mined to some extent. Generally speaking, however, the western part of Canada is not yet ready to engage in iron ore production, though steel-working plants already exist in Alberta, and a new one has recently been constructed near Red Cliff. The iron and steel industry is one of the foundation stones of national prosperity, and our neighbors of the country of the maple leaf are to be congratulated on the progress they have made in its development.

The Bromo-Cyanide Process Litigation

A patent case of much interest to metallurgists was recently decided at Perth, Western Australia. It was the suit of the London & Hamburg Gold Recovery Company, Limited, which controls the Sulman-Teed and Goepner-Witter bromo-cyanide patents *versus* the Golden Horse-Shoe Estates Company, Limited, operating at Kalgoorlie, the claim being for damages for infringement of the plaintiff's patents. The case has attracted considerable interest on account of the many delays since action was first started, the technical nature of the subject, and the strong counsel and able metallurgists appearing for both sides. Justice McMillan gave his reserved judgment on June 26, and details have recently been received. It will be recalled that in wet-crushing mills, ores containing tellurides of gold, silver, and other minerals, are not amenable to treatment in ordinary solutions of potassium or sodium cyanide with satisfactory extraction, except with the addition of an accelerator; a haloid compound of cyanogen such as bromide of cyanogen being found to work best. By adding this, the rapidity of the solution of tellurides is greatly increased. The reaction is as follows:

which is a pure cyanidation reaction. No oxygen is necessary, since it takes no part in the reaction. These among other points were established by Mr. H. Livingstone Sulman in a paper he read before the Institution of Mining and Metallurgy in 1898. Mr. Ludwig Diehl experimented on Kalgoorlie sulphotelluride ores for a considerable time, and at last devised the treatment known as the 'Diehl process.' This process is a combination of several steps, namely, wet-crushing by stamps with or without amalgamation, concentration, classification, fine grinding in tube-mills (Mr. Diehl being the first to use these mills in the reduction of gold ores, this being at the Hannan's Star mill in 1899), agitation of the slime with bromo-cyanide and potassium cyanide, and separation of gold solutions in filter-presses. The combination of processes, but principally the fine grinding and use of bromo cyanide, led to satisfactory recoveries, and the wet-treatment plants at Kalgoorlie adopted the process.

In operation, an agitator is filled with thickened slime, the ordinary strength of KCN is made up, and the pulp agitated for several hours. In this part of the mill is a small wooden mechanical mixer into which is run a certain quantity of water and

sulphuric acid which is then stirred about an hour. Mixed bromo salts, potassium bromide and potassium bromate, are then added to the dilute acid in the mixer and stirred for some hours. At the same time a quantity of strong potassium cyanide solution is added to the mixture. No haphazard work will suffice in making up the bromo solution, and for every charge there is a particular solution. The temperature of the mixture must also be watched. There is a maximum strength of bromo-cyanogen solution that must not be passed, or else there will be decomposition of the joint solvents, BrCN and KCN, with liberation of brown paracyanogen. When the bromo-cyanide mixture is ready, it is run into the agitator, and after the requisite contact with the slime, lime is added and the slime is filter-pressed. Precipitation is on zinc shaving as usual. A detailed description of this process, written by Mr. E. W. Nardin, was published in the *Mining and Scientific Press* of October 24, 1908.

In his decision, Justice McMillan stated that two patents came into question in the action, namely, the Sulman-Teed, and Goepner-Witter, Western Australian patents No. 601 and 3145, respectively. Regarding the Sulman-Teed patent, the defendants had urged every objection open, but some of these depended upon the construction placed upon the specifications. It was urged that Mr. Gaze, of Westport, New Zealand, was the real inventor of the 1894 process. The Judge ruled that the Gaze patent was not, as claimed, a patent for the manufacture of the halogen compound of cyanogen, but that the latter was intended to be used with potassium cyanide, however obtained, as a solvent for gold and silver. Another objection was that, according to the cyanide practice at the date of the patent, since lime was added in excess, and percolation was used, the new solvent could not be successfully adopted. The evidence of experiments forced the Judge to the conclusion that until the Diehl process was evolved, bromo-cyanide was a failure. As used by Gaze the solvent was a short-lived one, and caustic alkali destroyed the bromide. Therefore, he declared the Gaze patent invalid.

The second patent, the Goepner-Witter, was for the manufacture of bromo-cyanogen by mixing a bromate, a bromide, an acid, and an alkali cyanide. The defendants stated that there was nothing new in that. Evidence was conflicting, but the Judge decided that the process constituted an invention. It was then objected that this had been anticipated by the Sulman-Teed patent and the Morgans patent, but the defendants could not satisfy the Judge to this effect, he holding that the Goepner-Witter patent was valid and the defendants had infringed. Justice McMillan said that great praise was due to the work that had been done by Mr. Diehl at Kalgoorlie. Both sides have since appealed to the Privy Council in England, the plaintiffs against the invalidation of the Sulman-Teed patent, and the defendants against the validity of the Goepner-Witter patent. While not used by many mining companies in the world, the bromo-cyanide process is of great value on certain ores, as has been proved in the successful treatment of Australian tellurides.

The Trinity-Balaklala-Vulcan Mines, Shasta County, California

By W. H. STORMS

The seemingly almost hopeless problem of smelter fumes at the smelters of Shasta county, California, appear at last to be in a fair way of being solved. After the expenditure of a large sum of money, and repeated trials, the Mammoth Copper Co. equipped its smelter at Kennett with an extensive 'bag-house,' and other necessary apparatus, and its large plant has now been in apparently successful operation for several months past. This is certainly most encouraging, and indicates that the smelter-fume trouble can be overcome elsewhere by the employment of similar means, but there is evidently another way to handle the fume difficulty, for the First National Copper Co., whose property (the Balaklala mine and other claims of that group) is situated seven

of this part of Shasta county. The Iron Mountain mine which is essentially similar to the mines here to be described, is four miles to the south, the Stowell about two miles southeast, and the Mammoth three miles northeast. In addition to these large mines there are numerous prospects, some of which give promise of becoming great some day. Few of the mines of this region give pronounced superficial evidence of the great sulphide orebodies lying beneath. True, the Iron Mountain had a large limonite gossan, but it was practically destitute of copper and in its early history was equipped with a mill and was worked with some success as a silver mine, no one evidently having a suspicion at that time of the vast masses of copper sulphides ly-

BALAKLALA SMELTER.

MAIN TERMINAL, BALAKLALA.

miles west of Kennett, is now engaged in the rehabilitation of its smelter at Coram, a short distance below Kennett, on the Southern Pacific railroad. It is proposed, so it is announced, to put in operation at this plant what is called the Hall process, which is also claimed to render the noxious fumes from the smelters harmless to both vegetation and animals. Whether this process is all that has been claimed for it remains to be seen. It has received a favorable report from A. L. Walker, who studied the test plant at Brooklyn, N. Y., and large-scale tests at Coram should be under way before October. Results will be awaited with interest.

The Copper Belt of Shasta County

The continued successful operation of the Mammoth mine and smelter and the work now going on at Coram will undoubtedly direct the attention of copper people to the mines of this district. A great deal has already been written of the copper belt of Shasta county, but there always appears to be something new and important to add in connection with them. I had an opportunity, not long since, to go over the Trinity, the Balaklala, and Vulcan properties, spending several days on the ground, and found the geology of these mines most interesting. These several properties, each comprising a large group of claims, are contiguous, the Trinity claims lying north and east of the Vulcan, and the Balaklala group south of it, and extending southeast of the most southerly of the Trinity claims. These mines are 7 miles west from the smelter town of Kennett, and may be treated geologically as a single property. They are in the heart of the copper belt

ing beneath the iron outcrop. This lack of superficial mineralization at most of the mines has made prospecting in the region both difficult and expensive. In this connection the diamond-drill has proved to be a most important factor in the development of the district, not only in prospecting from the surface but from the underground workings, and it is certain that this method of searching for orebodies in this district will become even more common, as it is recognized as the most sensible and least expensive way to search for the hidden bonanzas of this region.

Geology

The rocks of this vicinity have afforded a subject for much discussion among geologists. H. W. Fairbanks, who was one of the first competent men to scientifically investigate this region, described the rocks generally (11th Report State Mineralogist) as a very acid quartz-porphyry. J. S. Diller, of the United States Geological Survey, has distinguished two series of eruptive rocks in this district—an older greenish rock, which he has called meta-andesite, and a lighter colored, usually distinctly porphyritic rock, which he has called meta-rhyolite. L. C. Graton, also of the United States Geological Survey, apparently is willing to accept Mr. Diller's classification of the older rocks, (the meta-andesite), but suggests for the more acid rock the name alaskite-porphyry for the reason that the so-called rhyolite of Diller shows neither glassy base nor any indication of devitrification, either of which is a distinguishing characteristic of rhyolite. It is unimportant, from a commercial point of view, however,

whether this rock be called rhyolite or alaskite, for it can readily be recognized both on the surface and underground by the abundance of quartz phenocrysts always present. The rock is both fine-grained and coarsely granular, but always presents characteristic facies which distinguish it from the andesite.

The Ore Deposits

In this portion of the Shasta copper belt, which is one of the most important in the United States, the development of the mines seems to have made clear several important facts. The most significant of these are: First, that the great orebodies occur exclusively in the acid rock—the rhyolite of Diller, or alaskite of Graton. Second, that the mineralization has taken place in zones of shearing and brecciation, and is the result of impregnation and replacement of the original constituents of the rock, and that this alteration from rock to ore has proceeded in places on an astonishing scale. Huge masses of iron-copper sulphide occur where was originally only barren rhyolite. Having a knowledge of these facts the natural inference to be drawn from it is simple. It is to be inferred that mineralization has progressed to the greatest extent where the shearing and brecciation has been the most pronounced. An inspection of the mines of the region fully sustains the above conclusion. A fine illustration is presented in the open-cut on the Windy Camp orebody of the Balaklala mine. This body of ore lies beneath the surface of a spur of the hillside formed by the two branches of Windy Camp gulch. The ore comes within a few feet of the surface but does not reach it. The overlying rock is the white rhyolite slightly stained by iron oxide. The rhyolite is rather massive and gives little indication in its physical appearance of the close proximity of a large body of valuable ore just below. As soon as the ore is entered, however, the condition of brecciation and shearing of the rock mass is plainly seen, for this structural feature is still well preserved in the body of the ore itself. Here the two conditions may be inspected side by side—the massive unmineralized rhyolite above, the sheared mass below, now completely altered to ore. This exposure of one of the principal orebodies of the Balaklala mine teaches a very valuable lesson. It shows how the ore has formed in the sheared and crushed zone of the originally barren rhyolite, and it also indicates how close mine workings may pass to a valuable body of ore and miss it, its presence being, perhaps, entirely unsuspected. This emphasizes the need of systematic prospecting in the search for unexposed orebodies.

The Meta-Andesite Rocks

The meta-andesites are found over a large area in this region. They represent a thick series of ancient flows, tuffs, and more rarely conglomerates, with an occasional dike. These old rocks are all of what may be considered as practically a contemporaneous period. In them are found gold-bearing quartz veins (the Unele Sam and Gladstone are types), and it is from these, and from seams and pockets of gold in these rocks that the placers of the neighboring gulches derived their gold. The placers have been worked quite extensively, and are practically ex-

hausted. These ancient andesites have been intruded by an immense mass of the acid rhyolite above referred to, and which is now the main ore carrier of the region. The north fork of Squaw creek marks the line of contact between the great eastern mass of meta-andesite and the ore-bearing rhyolite. The latter rock, in its passage from below, has torn away great strips from the older andesite and has included them in the rhyolite. I

SMELTER OF MAMMOTH COPPER COMPANY.

observed one of these great fragments particularly, in the Vulcan property, which is otherwise principally in the rhyolite area. This mass of andesite is not less than 3000 ft. long, fully 200 ft. wide, though varying somewhat, and extends downward no one can say how far. This large dike-like mass of andesite is important in the Vulcan property, as it appears to occupy a definite place with reference to the mineralization of the rhyolite in this vicinity. A knowledge of this fact will be of undoubted value to the owners in directing prospecting in the ore-bearing rhyolite.

Trinity and Vulcan Mines

In the Trinity mine the ore lies wholly in the rhyolite and east of the andesite strip, but in close proximity to it at the west end of the Trinity orebody. In the Vulcan ground the largest gossans and surface indications of mineralization are also found on the east side of the andesite strip, the conditions there being practically a duplicate of those in the Trinity. The largest orebody thus far found in the Trinity mine and which has been developed by adits and further explored by diamond-drill, apparently passes across the property line into the Vulcan. West of the andesite strip on the Vulcan are other indications of ore in depth. Some of these are of large size and may cover very extensive deposits of sulphide ore. Several adits have been run in the Vulcan ground, both east and west of the andesite strip, but these workings, owing to a lack of knowledge and an appreciation of the conditions present on the part of the owners, have been of little usefulness in developing ore, though some of the adits may be utilized later for both drainage and transportation when the property is more extensively developed. One of these adits is 1400 ft. in length, and may have passed near bodies of ore, but little indication of their proximity is to be seen in the long adit. Diamond-drilling may be done to advantage from this adit, as footage would be gained by setting a drill here.

Diamond-Drilling

As previously stated, the most satisfactory method of prospecting this region is by means of the diamond-drill. This is the method that has been employed at all of the large mines of the district, from the Iron Mountain to the Mammoth. At some of the mines there is little other development. The Stowell, I am told, has been extensively prospected in this manner, but has limited development otherwise. At the Balaklala numerous diamond-drill holes have been bored with highly satisfactory results. The same may be said of the Trinity, the Mammoth, and others. At the Vulcan several diamond-drill holes have been put down and ore found in each of them, but the holes are all of limited depth, being about 300 ft. each. Just across the cañon of Squaw creek (south fork) two holes have been bored in the Balaklala to a depth of 1500 ft., I was told, and good ore found. Wherever drilling is undertaken in this region the work should be done systematically and thoroughly, or the money will be wasted. It is an easy matter to drill holes here to any depth within the capacity of the drill and find no sign of ore. The orebodies appear to lie at a rather low angle, dipping, if at all, slightly to the westward. Faults occur and these are liable to dislocate the bodies of ore. For this reason down holes rather than flat ones are advisable. One of the holes on the Vulcan is flat. It passed through 27 ft. of sulphide ore, but it is not known whether this is a flat sheet of small dimensions or a portion of a large orebody. One vertical hole, at a depth of 249 ft., passed through a body of ore carrying $4\frac{1}{2}\%$ copper. I was informed that the great orebody of the Trinity mine abutted upon the andesite strip previously referred to. As the mine was not open to inspection, I was unable to verify this assertion, but have no good reason to discredit the statement.

Diamond-Drill in Underground Exploration

The diamond-drill has been employed in the underground workings of the Trinity, for upward holes have been drilled near the most westerly line of the mine workings and 20 or more feet of solid ore found. Whether this ore extends unbroken into the Vulcan I am unable to say, for there is some indication at the surface of the occurrence of a fault near the west line of the Trinity. If this fault actually occurs it will, I think, be somewhat to the advantage of the Vulcan, as it would bring the orebody nearer to the surface, and thus render it more easily accessible. About 1000 ft. west of the line of this suspected fault (the evidence at the surface is obscure) are indications of a second fault, parallel with the first. The heavy iron outcrops are still west of this latter fault, and above the line which it is supposed to follow. If this assumption is correct, then the Vulcan-Trinity ground is cut by a series of parallel step-faults, similar to those known to occur at the Iron Mountain mine, and any orebodies found in any one of these blocks of ground would consequently be cut off by the fault, only to reappear in the next block to the westward and at a higher level. The whole situation is extremely interesting and full of possibilities of ore occurrence

at a number of places in addition to those mentioned above. Faults of similar character are described as occurring between the Iron Mountain and Hornet mines, four miles south of the Trinity.* Here, what appears to have been at one time a continuous body of ore is broken and separated into a number of blocks, in the same manner as those in the Vulcan-Trinity ground. On the Vulcan there are at least five separate areas where indications at the surface, as far as they can be relied upon, seem to mark the presence of ore in depth. The correctness or falsity of this conclusion can best be proved by the diamond-drill. In some of the larger mines of the district, miles of diamond-drill holes have been bored, and while the numerous holes have not in every instance discovered ore, it is acknowledged by the mine managers there that the diamond-drill is by far the best method of searching for ore and for determining the approximate shape and value of the deposit. On the Vulcan property an adit has been driven a few feet above Squaw creek. There is mineral the entire length of this tunnel, and that part of it near the face makes by far the better showing, and yet little is known of the size and value of this particular mass of ore. Diamond-drilling would have given much more information and at less expense.

Surface Indications

The search for bodies of ore in a region like this, where the surface indications, for the most part, consist of what the miners call 'copper blossom,' which is the name by which they know the various masses of iron-stained rock of the region, makes this work difficult. These copper blossoms do not consist of solid iron oxide, which is even here distinguished from the 'blossom' and is called gossan, as it generally is elsewhere. There are a number of these gossans in the district, some of them large, like that at the Iron Mountain; but there are also large and valuable bodies of ore developed where no gossan occurs, as at the Balaklala orebody in Windy Camp gulch previously referred to. The Trinity has a great iron gossan that outcrops on the side of a steep hillside. This exposure is practically a cliff, due to the erosion of the south fork of Squaw creek. The rock overlying this mass of ore is rhyolite of dazzling whiteness, with no sign of copper minerals and little of iron. Had not Squaw creek cut down through the rocks at this place, the Trinity orebody might never have been discovered, for there is no encouragement in the appearance of the rhyolite above it to lead one to hope that ore might be found below. The big gossan, however, was sufficient to attract the attention of the most casual observer, and the development of the mine soon revealed valuable ore. Just north of the principal workings of the Trinity mine a gulch known as Skookum enters the cañon of the south fork of Squaw creek. Up near the head of this gulch, which is only about 3000 ft. long, there is a large area of brecciated and iron-stained rock, the 'copper blossom' of the prospector. There is no sign of copper to be seen at the surface,

*Donald F. Campbell, in *Mining and Scientific Press*, January 12, 1907.

but at one point, on the Hiyon claim of the Vulcan group, an adit has been run into the crushed-rock mass and, within 10 ft. of the surface, sulphide ore carrying some copper was discovered. It is not probable that the ore found at this place is normal ore, for without doubt much of the copper it originally contained has been leached. A similar area occurs over the long adit driven from Squaw creek into the Vulcan ground, and it would not be at all surprising later to learn that this adit has been run underneath the ore horizon of that locality. If the faults heretofore referred to as probably occurring, do actually exist, it is almost a certainty that this adit has been run under the ore. Here is a fine opportunity to employ the diamond-drill in a systematic manner. On the Balaklala west of the Windy Camp orebody, similar conditions exist, that is, large 'copper blossoms' occur, and the indications, such as they are, point to the existence of more ore in that direction. A little tunnel work has been done in that vicinity and some good ore found, but thus far in only small amount. The fact that ore is present at all is looked upon as an encouraging sign by the miners of the district, for they have so frequently seen large masses of ore developed where the superficial indications were not encouraging, to say the least, that they have gained much confidence in their own judgment of indicative conditions. This is the one thing that impresses the mine geologist in this district—the finding of large masses of ore by the employment of the diamond-drill where the superficial indications would not seem to warrant drilling at all. This is the case from the Iron Mountain to the Mammoth, and is particularly to be observed on the Balaklala, in the Windy Camp orebody. Not that the latter occurrence is unusual in the district, for it is not, but for the reason that the geological conditions are so clearly exposed in the open-cut at that mine. The occurrence of the great Trinity orebody under the unmineralized white rhyolite is another, and it is such occurrences as these that have given the mine managers of the district the courage to bore miles of holes with the diamond-drill, in territory that ordinarily would be considered not only as unfavorable, but as having no chance for ore whatever. Of the many holes bored in the district, a large number have passed through ore, and some of the largest orebodies of the district have been discovered in this manner.

Economic Conditions

The region in which these copper deposits occur is one of high and steep but not, generally speaking, rugged hills. The transportation problem has been solved by the construction of good wagon-roads and trails for ordinary purposes, and by the building of narrow-gage railroads or wire ropeways, or a combination of both, for the carrying of ore from the mines to the smelters. The serious obstacle in the way of the extensive development and operation of the mines of this region has been the disposition of the smelter fumes. This has resulted in the closing of the various plants from time to time, the Mountain Copper Co. even going so far as to abandon its smelting plant at Keswick

and construct a new and better one at Bay Point, in Contra Costa county. The Mammoth Copper Co., in order to perpetuate the great industry that had been started by it, began a series of experiments. The result of the efforts in that direction is seen in the large addition to the Company's smelting plant at Kennett. This great bag-house took months to build and cost half a million or more dollars, and has required numerous changes and additions since it was first thought to be complete; but it now seems to meet every requirement, as far as rendering the fumes harmless is concerned, and there is accumulating at the smelter thousands of tons of dust from the bag-house that is said to contain a good percentage of zinc in the form of sulphate. This material is thus far without commercial value, but efforts are being made to solve this metallurgical problem. With the success of the Mammoth company, and the promised equal success of the Hall process to be installed at the smelter of the First National company, the copper district, from Iron Mountain to the Mammoth, will take on new life and the output of copper in California will no doubt be largely increased as a direct result of these new processes.

Mining in Morocco

Morocco is reported to be a country rich in mineral resources. Mining development will take place when the mountainous regions of the country have been sufficiently pacified to permit operations. It is likely that mining interests will be eventually consolidated under an amalgamation of the several syndicates now in operation. The Union des Mines and the Mannesmann group have recently combined, but at present there are still several independent companies making surveys and staking out claims in various parts of the country.

There is no mining code in Morocco, and pending the promulgation of the code, which is under preparation, the position of the prospecting syndicates is somewhat ill defined. Mineral areas are located, surveyed, and the denouncement filed by the prospector at his legation. Upon the promulgation of the mining code an international board of arbitration will sit to adjudge, according to priority, the claims thus filed.

It is reported that the tentative draft of the mining regulations for Morocco, which has been drawn up by the Spanish inspector-general of mines and the director of the public works department in the French zone in Morocco, has been finished. These regulations are said to differ considerably from those drawn up in 1910 by the delegates of France, England, Germany, and Spain. The extent of the concessions for experimental works will be granted by the square metre. The tax will in some cases be raised, but will be uniform for most of the concessions.

It is rumored that questions of rights arising before the promulgation of the mining regulations will be settled by special tribunals appointed by the French and Spanish governments in their respective zones, instead of by the tribunal at Lausanne, as was originally proposed.—*Daily Consular Report.*

Nickel Smelting by the Mond Process

By A. P. COLEMAN

*The carbon monoxide process of refining nickel, by which a volatile compound of nickel is produced and afterward decomposed, thus depositing the metal, was discovered by Carl Langer while working on other problems in the laboratory of Ludwig Mond. Having found a method of refining the metal, Mond naturally looked for a deposit of nickel ore, and in 1899 bought what was then called the McConnell mine, on the north half of lot 8, con. IV, of Denison township, about 3 miles northeast of Worthington in Ontario. Smelting works were established beside the 'Soo' branch of the Canadian Pacific railway, two miles south of the Victoria mine, as the deposit was named, and a cable tram-

During this year the Garson mine began shipping ore to the Victoria mines, by the Canadian Northern railway to Sudbury, and then by the 'Soo' branch of the Canadian Pacific to the smelter. By this time the Victoria mine and smelter were equipped with electric power, from Wabageshik falls on Vermilion river, nine miles to the southwest; and the Garson mine was operated with current from the Wanapitei river.

In 1910 diamond-drilling was done to test the Cochrane and McVittie property, which covers a corner of the great Frood deposit, and this was purchased to furnish an additional supply of ore. The Mond company has the distinction of working the deepest mine in Ontario, and in spite of rather small ore deposits the Company is prospering, having recently built much larger smelting works, doubling the size of its refinery at Clydach.

New Smelting Plant

¹As a reflex of the present prosperous condition of the Company, a new smelting plant has been built near Coniston, where 3700 acres has been acquired for the purpose. The new site is much nearer the present chief producing mines of the Company, is but a short distance from one of the electric-power plants of the Wanapitei power company, and has an ample water-supply. The plant is designed for a capacity of 2000 tons of

OLD MOND SMELTER, VICTORIA MINES.

way was constructed to transport the ore 11,000 ft. from the mine to the smelter. In 1900 the Mond Nickel Co. was formed, with a capital of £600,000, to take over the mine and smelter, and in the following year bessemer matte was being produced under the management of Hiram W. Hixon. The roast yards were at first near the smelter and village, but after a fire at the landing station of the ore, necessitating more or less reconstruction, the roast beds were removed to a flat half way between the mine and the smelter. Trouble with the refining works at Clydach, near Swansea, Wales, caused delays on this side of the water also, but ultimately the Mond process was brought into good working order, and the Company began to look for new sources of ore, since the Victoria mine is not a very large deposit.

After testing some small deposits, such as the North Star and the Little Stobie, in 1907, a larger one was purchased toward the east end of the main nickel range and named the Garson mine, from the township in which it occurs, on lot 5, con. III. C. V. Corliss, who had been mine superintendent, became manager on the resignation of Mr. Hixon in 1908, and O. B. Hall was made mine superintendent.

ore per day, and is in general similar to the plant of the Canadian Copper Co., with the exception that no reverberatory furnaces are used. It is probable that when the supply of fine ore and flue-dust reaches its maximum, a Dwight-Lloyd sintering machine will be installed to handle it. The mine ore, containing nickel and copper in about the proportion of 2.6% nickel to 1 of copper, and with a 25% sulphur content, is roasted in heaps, the roasting yards being so placed that the sulphur fumes will not cause trouble. When the sulphur content is reduced to 11 or 12%, the roast heaps are reclaimed with steam-shovels and the ore loaded into cars which transport it to the smelter bins. The ore, limestone, and coke are drawn out through hoppers into charging cars, and weighed in the usual way, and are then dumped directly into the blast-furnaces. These are 50 in. wide and 20 ft. long. Using a height of charge above the tuyeres of 11 ft., and a blast pressure of 30 to 40 oz., about 500 tons per day is smelted, making a slag that runs 30 to 40% SiO_2 . Space has been provided for four blast-furnaces, two are already constructed, and one is in blast. The plant has only been in operation two or three months, so that working conditions are still some-

¹The description of the new smelting plant has been supplied by the Editor.

what abnormal and the coke consumption is accordingly high. The furnace yields 70 to 80 tons per day of matte containing about 20% of copper and nickel combined. This is tapped off from the settlers into pots handled by the crane and is dumped into the Pierce-Smith converter, where it is blown to a matte containing 80% copper and nickel combined. As a result of closing down the old plant and starting the new, a large amount of difficult

received 18% in 1906, 33% in 1907, 48% for the next three years, and now 55.5 per cent.

The Mond Process

The matte produced at Coniston is shipped to Clydach, a suburb of Swansea, Wales, for final treatment by one of the most ingenious processes imaginable. It was discovered in 1889 by Carl Langer, working in conjunction with Ludwig Mond, that

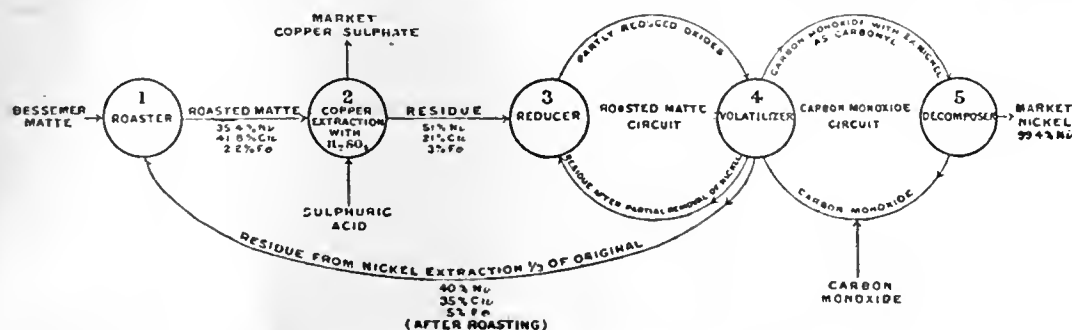

FIG. 1. DIAGRAM ILLUSTRATING THE OPERATIONS INVOLVED IN THE MOND PROCESS.

material requires to be handled, and the converter is made to do as much smelting work as possible. It is therefore worked to capacity in spite of the apparently small tonnage of matte treated. The converter slag is poured directly into the blast-furnace settlers.

Financial Statement

The following statement has recently been made as to the financial conditions of the Company: The original capital of the Company was £600,000, divided into £250,000 of 7% cumulative preference £5 shares, £300,000 ordinary, and £50,000 deferred shares of £1 each, without debentures or other prior charges. The ordinary shares carried a preferential dividend of 7%, thereafter sharing with the deferred shares in surplus earnings. In 1908 the capital was increased to £850,000 by the creation of 50,000 cumulative preference shares, of which 30,000 were issued, raising the preference share capital to £400,000. It was not until 1905 that the profits of the Company provided any return to the ordinary shareholders, since when they have gone up by constant increases, and the returns for the past three years have been:

	Year to April 30:		
	1909.	1910.	1911.
Net profit	£111,320	£114,107	£140,803
Preferred dividend, 7%	22,716	26,367	26,367
Ordinary dividend	42,751	42,375	45,906
Ordinary rate, per cent.	15	15	16½
Deferred dividend	22,800	22,600	26,131
Deferred rate, per cent.	48	48	55½
Balance of year	23,053	22,765	42,399
Brought in	29,923	32,976	20,741
For reserve, etc.	52,976	55,741	63,140
To reserve	20,000	35,000	35,000
Carried forward	32,976	20,741	28,140

In 1906 the ordinary shareholders first received a dividend over their stipulated 7% when 10% was paid, followed by 12.5% in 1907, 15% for the next three years, and now 16.25% for the past twelve months, while the holders of deferred shares re-

ceived 18% in 1906, 33% in 1907, 48% for the next three years, and now 55.5 per cent.

FIG. 2. VERTICAL SECTIONS THROUGH THE DECOMPOSER.

was patented and an experimental plant was erected in 1892, at Smethwick near Birmingham, to test it. As described by Roberts-Austen in 1899, the process was developed during some years of patient work, in which the plant had several times to be reconstructed to make it a practical success.²

²Minutes of the Proceedings of the Institution of Civil Engineers, Vol. CXXXV, p. 29.

Operations Necessary for Production of Nickel

Essentially five operations are required in order to produce the nickel: (1) dead roasting to drive out as much of the sulphur as possible; (2) the extraction of about two-thirds of the copper by sulphuric acid, the resulting sulphate of copper being sold in that form; (3) the reduction of the nickel and remaining copper to the metallic state by water gas or producer gas rich in hydrogen in an apparatus called a 'reducer', the temperature of which is under perfect control, so that 400°C. is never exceeded; (4) from this apparatus the substance, now reduced to the metallic state, is taken through

In operation (5) the carbon monoxide is released and is returned to the volatilizer to take up a fresh charge of nickel. When the operations are in progress the carbon monoxide gas and the partly reduced oxides of nickel and copper are continually revolving in two separate circuits which join and cross each other in the volatilizer (4). The nickel is deposited on granules of ordinary commercial nickel which are automatically removed after reaching a certain size. The product contains between 99.4 and 99.8% of nickel.

Roberts-Austen describes the process as he observed it at Smethwick as follows: "The material

under treatment during my visit was of Canadian origin, and had been received as calcined matte containing 35.4% of nickel, 41.8% of copper, and about 2% of iron. This material was first passed through a ball-mill and dresser with a 60-mesh riddle, and was then treated in quantities of 3 cwt. in a small lead-lined mixer with 200 lb. of ordinary sulphuric acid which had previously been diluted with about 20 cu. ft. of mother liquor from previous operations. These appliances are shown in the right-hand portion of the plan and elevation, Fig. 2. The temperature of the mixture soon rises by the action between the copper oxide and the sulphuric acid, and is kept, by means of a steam jet, at a temperature of about 85°C., for half an hour. From this mixer, the charge is run out into a centrifugal hydro-extractor, provided

FIG. 3 AND 4. GENERAL ARRANGEMENT OF MOND PROCESS PLANT.

air-tight conveyors and elevators into another apparatus called a 'volatilizer', in which it is subjected to the action of carbon monoxide gas at a temperature not exceeding 80°C.; (5) the nickel carbonyl thus produced passes into the 'decomposer,' a tower or horizontal retort heated to 180°C., so as to release the nickel in the metallic state.

Time of Operation

The process is not complete in one passage through the five stages, however, and the materials are made to circulate for a period varying from 7 to 15 days between stages (3) and (4) until about 60% of the nickel has been removed as carbonyl. The residue from this operation, amounting to about a third of the original calcined matte and not differing much from it in composition, is returned to the first operation and follows the same course as before.

with a filtering cloth, in which the solution of copper sulphate is separated from the solid residue containing the nickel. After the filtration of the charge is finished, the speed of the hydro-extractor is increased.

Crystallization of Copper Sulphate

"The solution containing the extracted copper runs from the hydro-extractor into a well, from which it is pumped into the crystallizing vats shown in Fig. 3. After a period of about 8 to 10 days, the crystals of copper sulphate are taken out of the vats and the mother liquor is mixed with fresh acid and is again used for the extraction of copper. As already mentioned, a small amount of nickel and a little iron are also dissolved in the sulphuric acid during the copper extraction, so that the mother liquor from which the copper sulphate has crystal-

lized becomes gradually contaminated with these two metals. It is therefore necessary to replace some of the mother liquor from time to time by fresh water, and to recover the nickel from the solution. The simplest method is to evaporate the solution to dryness and to roast the nickel and copper sulphates so obtained. The oxidized material is again introduced into the main process. The copper sulphate crystals from the crystallizing vats are charged into a second hydro-extractor, where they are washed with a little clean water to remove all acidity; they are then dried and are ready for packing. The copper sulphate thus obtained is suffi-

ciently pure for market, as it contains only 0.05% of nickel and 0.048% of iron.

roasted matte falling on these shelves from above, is stirred and made to descend from one shelf to that below it by rabblers actuated by a central vertical shaft. Water-gas passes up the tower to effect the reduction of the material. There are about fourteen of these shelves or trays in the tower. The five lower shelves are not heated by producer gas, but are cooled by a stream of water in order to reduce the temperature of the roasted and reduced matte to the temperature at which the volatilizer is worked.

Volatilizing Tower

"The volatilizing tower resembles the reducer, but

FIG. 5. ARRANGEMENT OF REDUCERS AND VOLATILIZERS FOR EXTRACTION OF NICKEL.

ciently pure for market, as it contains only 0.05% of nickel and 0.048% of iron.

Residue from Copper Extraction

"The residue from the copper extraction is taken from the hydro-extractor and stored in a bin until a sufficient quantity has been collected to make up a charge of 5 to 6 tons for the nickel extracting plant. It now contains 52.5% of nickel, 20.6% of copper, and 2.6% of iron. The material is charged by hand at the rate of half a ton per hour into a feeding hopper, described as the matte inlet in the lower part of the plan, Fig. 3, which communicates, through a rotary valve, with the conveyor, consisting of a tube enclosing a revolving spiral, which transports the material to an elevator. This lifts the material to the top of the reducing tower, and discharges it through another rotary valve into this reducing tower.

"The reducer and the volatilizer (shown in the centre of Fig. 3 and 4), in which the treatment with carbon-monoxide takes place, are fully described in Mond's patent, No. 23,665, December 10, 1895. The reducer consists of a vertical tower about 25 ft. high, containing a series of shelves, which are hollow so as to admit of their being raised to a temperature of 250°C. by producer gas. The

the shelves are not hollow, as there is no necessity to heat them. The reduced nickel requires a temperature of only 50°C. to enable it to combine with carbon monoxide and form a volatile compound, and the matte and gas are sufficiently hot to maintain this temperature. In the plant at Smethwick the volatilizer was made the same size as the reducer, but in the new plant it is somewhat smaller.

"The decomposer has been devised with much care, and has, in its present form, only recently been patented. The nickel is deposited in it, from its gaseous compound with carbon monoxide, on granules of ordinary commercial metal. The arrangements by which this is effected are very ingenious, and may be described almost in the words of Mond's latest patent. The object is to obtain metallic nickel from nickel carbonyl in the form of pellets, which are specially suitable for the production of nickel alloys. For this purpose gases containing nickel carbonyl are passed through granulated nickel, which is kept at the temperature required for the decomposition of the carbonyl, about 200°C. The nickel which thus separates from the carbonyl becomes deposited on the granulated nickel, which consequently increases in size. In order to prevent cohesion of the granulated nickel, it is kept in motion. When a number of the pellets have at-

tained a convenient size, they are separated by sifting without interrupting the depositing operation, the smaller granules being returned to receive a further deposit from the nickel carbonyl. A convenient form of apparatus for effecting the process described is shown in Fig. 2, which represents vertical sections of the apparatus on planes at right angles to each other. A is a cylindrical vessel, preferably built up of short cylinders, a a, bolted together; it contains a central tube, C, provided with gas outlet holes, O, through which the gas containing nickel carbonyl, entered at the gas inlet, B, passes into the vessel which is filled with shot, or small granules of nickel. The gas permeates through the interstices between these granules, and is brought into intimate contact with them, and when the nickel carbonyl is decomposed, the nickel is deposited on the granules. The gases finally escape through the outlets, L, into the gas exit pipe, M.

Movement of the Granules

"In order to prevent the granules from cohering, they are kept slowly moving by continuously withdrawing some of the granules from the bottom of the cylindrical vessel, A, by means of a right and left-handed worm conveyor, U, which delivers the granules into two sifting drums, N. The smaller granules fall on to the inclined plane, W, and collect at the base of the elevator, E, which conveys them again to the top of the cylinder, A, and feeds them through the feeding-hole, X. In order to avoid the deposition of nickel from the nickel carbonyl in the central tube, C, it is kept cool by causing water to circulate down the tube, F, and up through passages, F, formed in the central tube, to the water outlet F¹. The cylindrical vessel, A, is surrounded by a wrought iron casing, Q, which forms heating-spaces, H, communicating with heat flues, P, which are so arranged that the temperature of each cylinder can be separately regulated by dampers, so as to maintain the temperature of the granules of nickel contained in the vessel, A, at about 200°C., at which temperature the nickel carbonyl is decomposed. With a view to ascertain whether the cylinder, A, is full of granules, a rod, R, is fixed to the spindle of an external handle, which can be turned partly round, so that if the operator feels resistance to the motion of the R, it is certain that the granules extend to that height. The appliance used for depositing the nickel originally consisted of a series of retorts lined with tin steel sheets, on which the nickel was deposited in layers. It was found, however, that the metal so obtained was very difficult to cut.

"A magnified section of a granule of nickel shows a core of nickel with a crystalline and convoluted structure surrounded by concentric layers. The central core is ordinary commercial nickel, and the layers are nickel deposited from its carbonyl. In some cases granules of deposited nickel are found without any central core. These have grown from minute fragments of deposited nickel which have become detached during the course of deposition. The water gas used in the reducer is generated in gas producers, three of which are shown on the left

of the plan, Fig. 3. Anthracite is used to decompose the steam, and the water gas is collected in a gas holder, whence it is taken to the reducing tower, to which reference has just been made. This gas contains, on entering the reducer, about 60% of hydrogen.

Water Gases

"The reducing operation is so regulated that only a small quantity of hydrogen remains in the escaping gas, as a rule not more than 5 to 10%. This waste gas is subjected to the action of a fine water spray which condenses the steam generated by the combustion of the hydrogen in the water gas. Part of this waste gas is used for making the carbon monoxide required in the volatilizer, by passing it through the CO retort charged with incandescent charcoal, Fig. 4, which reduces the carbon dioxide contained in the waste gas, and this increases the amount of carbon monoxide in it. The gas issuing from this retort contains about 80% of carbon monoxide, and is stored in another gas-holder, which communicates with the main circuit of the carbon-monoxide gas. This main circuit of the carbon monoxide passes through the volatilizer already referred to, where the nickel is taken up. The carbon monoxide, now charged with nickel, passes through a filter to separate the fine particles of matte dust from the gases, then through an apparatus called the decomposer and so described in the figure. In this decomposer the nickel taken up in the volatilizer is deposited. The gas now deprived of its nickel passes to the CO blower, Fig. 4, which sends the carbon monoxide to the volatilizer in order that it may take up a fresh charge of nickel.

Circulation of Nickel-Bearing Material

"The solid material from which the nickel is being extracted is kept circulating through the reducer and volatilizer for a period varying between 7 and 15 days, during which time the oxides are gradually reduced to the metallic state and the nickel is volatilized. When the material originally charged in has had the bulk of its nickel extracted, it is run out through a rotary calciner roaster, Fig. 4, which converts the metals into oxides, so that they may be treated for the second time with sulphuric acid and carbon monoxide. The ratio between the nickel and copper in the residue from the nickel extraction is practically the same as in the calcined matte, with which the operations were started, but the amount of iron has increased by the removal of the copper and nickel, as the following figures show: Original matte contains, nickel 35.27%, copper 41.87%, iron 2.13%. After the first treatment of copper and nickel extraction, the quantities are: nickel 35.48%, copper 38.63%, iron 4.58%; and after the second copper and nickel extraction: nickel 35.83%, copper 35.56%, and iron 7.82%. The amount of nickel extracted in these two cases was, after the first treatment, 61%, and after the second treatment 80% of the nickel present in the original matte. It must be remembered, however, that in the second treatment only one-third of the original amount remains to be treated, while the final residue is only one-tenth. To avoid the formation of iron

carbonyl, the temperature in the reducer has to be kept very low, and if this is done, the nickel extracted from a matte originally containing as much as between 6 and 10% of iron will not contain more than 0.5% of iron. If the amount of iron in the residue rises above this percentage, the extraction of the nickel is very much delayed, on account of the low temperature which must be maintained in the reducer. It is necessary, in such a case, to remelt the residue before proceeding with the extraction of the nickel and copper. The following are analyses of the deposited nickel:

	I. (%)	II. (%)
Nickel	99.8200	99.4300
Iron and Al ₂ O ₃	0.1000	0.4300
Sulphur	0.0068	0.0099
Carbon	0.0700	0.0870
Insoluble residue	0.0260

“Fig. 5 and 6 show a front elevation, plan, and cross-section of a plant designed to produce 1000 tons of nickel per year. The plant is so arranged that the matte is continuously charged into the first reducer and traverses the whole set of appliances. When the matte issues from the last volatilizer the first nickel extraction is finished. The matte is re-roasted and submitted to the second copper and nickel extraction. There are ten appliances, consisting of one large reducer, eight combined reducers and volatilizers, and one large volatilizer. They are so arranged that the matte has first to pass through the large reducer, and is then lifted by means of an elevator and conveyor into a volatilizer (erected on the top of the next reducer). It passes through the volatilizer into the upper portion of the reducer and in traversing this it is further reduced. It is then lifted again to the next volatilizer, and so on until it finally reaches the larger volatilizer at the end of the whole series, and, after passing through this, it is discharged into the roasting furnace. The conveyor on the top of the volatilizers into which the elevators discharge, is common to the whole set of volatilizers and reducers, so that, in case any portion of the plant has to be disconnected, the rotary valve through which the material is discharged from the conveyor into the volatilizer is stopped. The material then passes on through the conveyor into the next volatilizer. The two gases, carbon monoxide in the volatilizers and water gas in the reducers, are kept separate by rotary valves of the same construction as in the small plant. The water gas connections are so arranged that each reducer receives fresh gas from the main, with the exception of the first large reducer, through which the waste gas of all the other reducers is passed, so as to burn completely all the hydrogen in the water gas. The carbon monoxide passes through the volatilizers from a common main, and is collected, after it has passed through the filters, in a main leading to the blower. From the blower the carbon monoxide charged with nickel passes through a set of decomposers, and again into the main which feeds the volatilizers.”

The works at Clydach are equipped in the way described by Roberts-Austen, but with many more units, so as to produce 1700 tons of nickel, 7000 tons of copper sulphate, and 800 tons of nickel sul-

phate, including a little nickel-ammonium sulphate. Langer states that the nickel now produced is 99.98% pure and is sold in the shot form to the Armstrong company for armor plate, and to smaller firms of steel workers and producers of german silver and nickel plate. Some is sold also to Arthur Krupp, and to a pure nickel goods company at Berndorf near Vienna. The works show none of the roughness and disorder of the usual metallurgical plant, but are as clean and as scientifically managed as a laboratory, everything being accurately adjusted, and the temperatures of the different parts being frequently taken and recorded. The gases employed

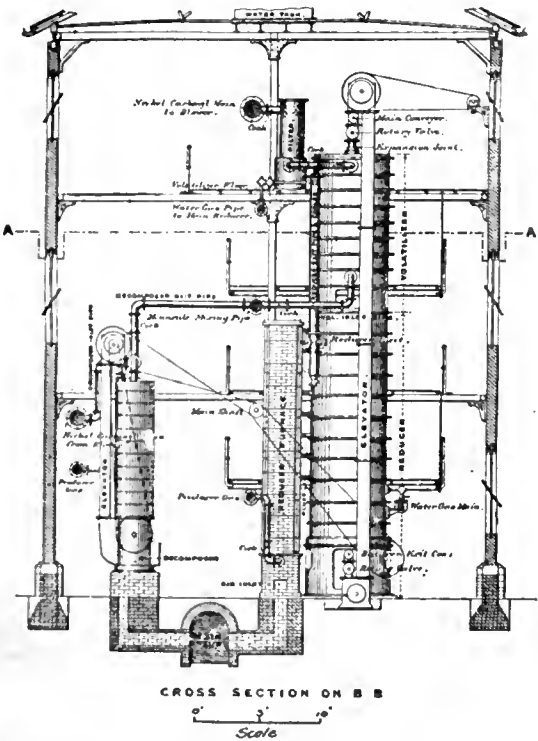

FIG. 6. CROSS-SECTION OF REDUCERS AND VOLATILIZERS.

in the process are very poisonous, but so much care is taken as to joints and fittings that for eight years there have been no cases of poisoning.

The plant is run continuously except for a stop of three weeks in the year to clean flues and repair machinery; and the demand for nickel has increased so much that plans are made to double the present works. Clydach, being in the midst of the Welsh anthracite and steam-coal fields, supplies at a minimum of expense the varieties of coal needed for the production of carbon monoxide and for other purposes in the running of the plant, and also gives a convenient distributing point for the sulphate of copper and other products resulting from the process. I am under great obligations to the Mond company for permission to visit the Clydach works, and to Mr. Langer for his courtesy in taking me through them.

Tin production of Bolivia in 1912 amounted to 42,305 short tons of black tin. The export duty on this was \$1,086,911, Great Britain obtaining 93% of the tin exported. The tin mining industry in Bolivia is in the hands of a few interests, the principal owner being Sr. Don Simon I. Patiño. The principal mines are found in the department of La Paz, Oruro, Potosi, and Cochabamba.

Primary and Secondary Ores Considered With Especial Reference to the Gel and the Rich Heavy Metal Ores

By P. KRUSCH

*The first to apply the principles of colloid chemistry to the study of ores was Cornu. In a paper published in the *Zeitschrift für praktische Geologie*, he dealt at length with the concept of metallogenetic type ores, previously advanced by me, and separated the ores of the several heavy metals into 'gel' and 'crystalline' ores. According to the then existing state of knowledge, he was justified in the assumption that the gels could play a rôle only in the secondary transposition of the metallic content of ore deposits; in other words, that they could not form primary deposits. Building upon the results obtained by Cornu, I have shown in the second edition of 'Untersuchung und Bewertung von Erzlagernstätten' (1911) that there are also primary colloidal ores, which are the products of original concentrations of ore. Since that time I have further occupied myself with the chemical and petrographic investigation of these ores. At this time I will indicate briefly the lines along which we are working at the Institute of Ore Deposits in Berlin, and will present some results of general importance.

Definition of Gel Ores

For the colloidal, originally amorphous ores that are produced from the so-called 'sols' resulting during weathering, I employ the term 'gel' ores. Even if by subsequent alteration they have become crypto-crystalline, they nevertheless differ markedly from the ores of similar chemical composition deposited in an originally crystalline condition. The colloidal ores may at some time after their deposition pass over into the crystalline state; for example, the gel ore polianite is commonly cut by younger veins of pyrolusite, and the gel ore limonite is filled with blebs and veinlets of crystallized iron hydrate. These are mainly transformations brought about by the agency of water. Perhaps more important are the facts, quite generally applicable to all gels, that increase of temperature and mechanical disturbance are often sufficient to cause a gel to become crystalline throughout its entire mass.

The recognition of the crystalline equivalents of the gel ores by Cornu has greatly clarified our knowledge of the origin and composition of the oxidized and hydrated ores of iron and manganese. The gels have the property of acting adsorptively upon solutions of the heavy metals, among others. This peculiarity often makes the recognition of their chemical composition a matter of difficulty. It is frequently impossible, therefore, to establish whether a gel ore represents a single definite chemical compound or is a mixture of two; that is, a gel forms one constituent and the adsorbed heavy-metal content the other. For these I desire to propose the terms 'gel groundmass' and 'adsorbed permeation compound'. To this kind of gel ores,

for example, belong the silicated nickel ores, which I am investigating at present in association with Beyschlag, in preparing the monograph on the nickel ore deposits of Frankenstein in Silesia. They are composed, as was already suspected previously, of a non-metalliferous gel, which forms the gel groundmass, and a nickel compound which constitutes the adsorbed permeation substance. Details will shortly be published by Mr. Kraft, one of Kemp's students who has been studying under my direction the relation between the deposits of amorphous magnesite and those of nickel silicate ores.

Adsorption Processes

The reverse phenomena was already known to Cornu that gel ores adsorb non-metallic substances, as, for example, manganese gel ore adsorbs barium and potassium compounds. Interesting experiments, undertaken by one of my students at my suggestion, are now in progress at the Berlin Mining School in order to determine the physical and chemical conditions necessary for these adsorption processes. The adsorption phenomena accompanying the permeation of a substance are excellently observable in thin sections. As I was able to establish in many instances, they are intimately associated with profound metasomatic processes, which may lead to a complete replacement of the original substance. Adsorption and metasomatism, therefore, go hand in hand; the first process is an extraordinarily favorable preparatory step for the second; both are so closely connected that one must speak of the whole process as 'adsorption metasomatism.'

Inasmuch as it is the processes of weathering that produce the gel ores and weathering is different with different latitudes, it is probable that the occurrence of the gel ores will show corresponding differences in this regard. I will recur to this point later. However, I must emphasize here that this question is most intimately related to the study of the secondary transposition of metals, which, as a matter of fact, is wholly determined by weathering. A systematic and exhaustive investigation of the differences in ores occurring in the different degrees of latitude is much to be desired, and would add much to our knowledge of the mode of formation of the gel ores.

Gel Ores Produced by Descending Solutions

Up to the present, unimpeachable results have been obtained only with the gel ores produced by descending solutions. Hydrosols are produced by the processes of weathering, and from them the gel ores originate. All the ores cited by Cornu are of such surficial origin. They are particularly common in the zone of oxidation, but are not, however, as Cornu assumed, restricted to that zone. Cornu's results can be stated summarily thus: Gel ores are amorphous oxide or hydrate ore-masses; they are of earthy, ocherous, or partly consolidated struc-

*Read before the International Geological Congress and translated by Adolph Knopf.

ture, and are restricted to the zone near the earth's surface.

The newer investigations are concerned mainly with the question of the depth at which these gel ores occur. The answer depends closely upon what changes occur in a descending solution that originated in the zone of weathering. In this connection it is necessary to distinguish in general between non-sulphide and sulphide ores. No easily reducible solutions will be found from the former; the most important distinctive criterion between the heavy-metal solutions in the zones of oxidation and cementation fails; there is absent, moreover, the reducing action of the primary sulphides that is absolutely essential to the processes of cementation. The properties of the solutions, however, remain unchanged in essence. The secondary transposition of metals can react at least down to ground-water level. In those regions which have undergone elevation as the result of tectonic causes and in which, therefore, the ground-water level has been relatively depressed, a very considerable vertical range may be brought about in an ore deposit throughout which rearrangement may take place. Inasmuch as in the case of gel ores originating from non-sulphide deposits the destructive action of high acidity of the solutions can not come into play, they may be formed throughout a very considerable vertical range.

Sulphide Orebodies

The conditions are more complicated in the case of orebodies rich in sulphides. In these, as for example, at Rio Tinto, there is a concentration of great masses of sulphur. If the total amount of sulphur, which upon weathering passes over into sulphuric acid, were to remain in the ore deposit, then the probability of the gels remaining undestroyed would not be great on account of the extreme acidity. Enormous masses of gel iron ore are nevertheless found in the gossan of these deposits. Great quantities of sulphuric acid have in fact been carried away. Sulphates are present in minute amounts only. The removal took place superficially, for the sulphur has remained intact at small depth. Proof of the action of acid is found in the signs of corrosion of the wall rocks, which now commonly consist of a skeleton of quartz.

Only a small part of the sulphate solution penetrated the orebody in depth and was reduced in the well known way by the undecomposed primary sulphides. To what depth is this gel ore, which is in fact exclusively iron gel ore, found? Only as deep as the action of oxygen is effective; in other words, they are restricted to the zone of oxidation. According to present knowledge, no gel ores are associated with typical cementation ores. The acidity of the descending solutions was probably too great for the preservation of the gels.

Finally, certain peculiar ore transformations, which persist to notable depths in the siderite veins of Siegerland without showing any evidence whatever of accompanying intensive processes of alteration, demand explanation. They are the development of metallic iron and specular hematite in fresh siderite. Bornhardt explained this in his mono-

graph on the veins of Siegerland (1912) as having been produced by reagents that penetrated the veins from the surface. In times of great aridity, as in the Permian, concentrated salt solutions were formed at the surface, and because of their high specific gravity sank down along fractures to considerable depths, exerting an oxidizing action by virtue of their absorbed oxygen. The author himself points out that the absence of any residual salt solutions of such a character is noteworthy.

In opposition to this hypothesis I have adopted the opinion of Wölbing, according to which the hypothesis of colloidal solutions is more probable. This would explain the extraordinary phenomenon of the complete absence of any products of oxidation, which, if Bornhardt's assumption is correct, ought to be present in so easily oxidizable a substance as siderite. The oxygen-bearing colloidal solutions have, on the other hand, the peculiarity that they do not give up their oxygen to the older ores.

Not only does circulation of the solutions take place in such processes along fissures, but there is also an extensive permeation of great masses without large open spaces. The alterations then take place, not in vein form, but in pockets which apparently stand in no relation to fissures. Such permeation by solutions of higher specific gravity, sinking from above, may persist down deep below the ground-water level. Gel ores may in such cases be found in the primary zone hundreds of metres below the ground-water level; the depth to which they may extend depends principally on the specific gravity of solution.

The gel ores are not restricted to proximity to the surface of the earth, where they are most common, but also occur at considerable depth. They are most common in the zone of oxidation, but may also form within the primary zone.

Gel Ores Deposited by Ascending Solutions

Up to the present time I know of no unimpeachable example of the origin of gel ores by ascending solutions, and can therefore only discuss the possibility of their occurrence. The conditions obtaining during weathering are most favorable for their development. These include low temperature, low pressure, presence of oxygen, and others. Ascending solutions practically never possess these properties at any considerable depth, but only after they have come in proximity to the surface, where they have become influenced by the surface and the conditions existent there. In depth, therefore, the conditions are unfavorable for the formation of gels.

The theoretical possibility of the formation of gels from ascending solutions, however, is not to be denied. In this connection experiments conducted by Wölbing, of the Berlin Mining School, are highly instructive. He has kept a silicic acid gel, prepared by the action of hydrochloric acid on a sodium silicate solution, for several years at a temperature between 80 and 100°C.; it still preserves its gel character, although a certain splitting off of water has taken place. The proof is thereby furnished that certain gels may persist at a high temperature during a considerable time. The dura-

tion of the experiment is, of course, short in comparison with the history of the earth, and the temperature small compared to those prevailing at great depths.

Further, many gels may be formed at 100°C., but all, in particular the sulphide gels of the heavy metals, have the tendency to pass rapidly into the crystalline state.

The influence of pressure on gels, which is also an important factor in ascending solutions, has not been sufficiently studied experimentally. The experiments carried out by one of my students, Mr. Nicolai, show that the highest pressures attainable in the laboratory were insufficient to cause crystallization. In all experiments there is, above all things, one factor absent, which nature—and only it—has at its command, namely, geologic time.

Our present knowledge concerning gel ores formed by ascension may therefore be summarized thus: not one example is known and the conditions obtaining at depth are unfavorable to the formation of gels.

Are There Primary as Well as Secondary Gel Ores?

The terms primary and secondary ores here demand explanation. Primary ores are (a) those of original concentrations; (b) those newly developed by younger ascending solutions (internal metasomatism of ore deposits in part). Secondary ores originate exclusively from descending surface waters (internal vein metasomatism in part). Cornu recognized only the secondary gel ores.

In earlier papers I have already pointed out that there are also primary gel ores; for example, the ores of iron and manganese. Bauxite, which is generally produced by the replacement of limestone by solutions originating by weathering, also belongs to this class. In the primary ores of gel character, I must place also certain lateritic products in which such notable accumulations of iron ore occur that they have been deemed worthy of exploitation. I know of such deposits in Europe occurring at Jerzu in eastern Sardinia. Novarese of Rome called my attention to these highly interesting deposits. In these cases the processes of weathering alone bring about the concentration, and because the gel ores thus formed are original deposits, they must be regarded as primary.

The genetic conditions are somewhat different in the case of the silicated nickel gel ores, which must also be considered as primary. They are the finest example of lateral secretion in the narrower sense of that term, and originated, so far as detailed investigations at hand show, through weathering. At Frankenstein, Beyschlag and I were able to verify this genesis. Whereas, in the examples previously cited, the solutions have effected a concentration of ore only near the surface, in the nickel ores the action has taken place in depth, so that an intense alteration of the serpentine has ensued along fissures extending from the surface to considerable depths. This phenomenon is excellently shown at Frankenstein, where quartz and chalcedony veins traverse the serpentine. The deposition of the nickel gel ores took place in the form of veins, or as highly irregular impregnations that end down-

ward with a trough-like form. The nickel content was originally held in olivine as a silicate, but this mineral can not therefore be called 'ore', and even during serpentinization no concentration of nickel took place. Furthermore, nickel is not—as assumed by many investigators—the most easily extractable constituent of serpentine; at Frankenstein I was able to obtain proof that the extraction of magnesite takes place considerably earlier. Later, under the influence of surface waters, the nickel-bearing solutions are formed, and from these the nickel ores are deposited. We must regard them as primary ores, which occur as a rule in the form of veins.

From these considerations it follows that primary gel ores may constitute workable deposits, and may even have been formed in close proximity to the surface or by descending solutions.

This result justifies the following conclusion: The gel ores, being products of weathering, must be subject to climatic control; that is, their composition, in deposits of recent origin, must stand in relation to the degree of latitude. I recall on this point the difference between our iron ores and laterite of the tropics in respect to the aluminum hydrate content; with the former it is almost exclusively enrichment of iron, and with the latter simultaneous bauxitization. A more careful and critical comparison of the composition of primary gel ores that have originated under different climatic conditions would yield results of great importance.

Origin of the Sulphides and Ores Rich in Heavy Metals

As is generally known, many of the heavy metals, for example copper, silver, and gold, form under favorable circumstances abnormally rich ores, associated with those of ordinary metallic content usually found in primary deposits. These are best known from studies of zones of cementation. These super-rich ores fall into three groups: (1) the rich sulphides, etc., of the heavy metals, such as argentite, pyrargyrite, covellite, bornite, chalcocite, etc.; (2) the native metals which have a weak affinity for oxygen, such as gold and silver; and (3) mixtures of the latter with the normal sulphides of the heavy metals, such as gold and pyrite, silver and galena, pyrargyrite and galéna.

The genesis of these three groups is not exactly the same: the rich sulphides, as can be established unquestionably in thin section, commonly coat the older normal sulphides, whose fractures they also fill. In a later stage they completely replace their hosts, so that there is finally produced a rich sulphide whose metasomatic origin by cementation is only to be recognized under favorable circumstances during high magnification by the presence of mesh-structure or minute remnants of the older normal sulphides. If one has luck with the sections employed, all the transitional stages may be observed between thin coatings and the filling of cavities in the normal sulphides, through all possible stages of metasomatism to the massive bonanza ore, which no one without further investigation would regard as the product of metasomatism.

Particularly interesting phenomena were discovered by me in thin sections of copper ores. In most deposits the primary copper ore is a cupriferous pyrite or a mixture of pyrite with minor amounts of chalcopyrite. In the zone of cementation there is first produced, as a rule, rich chalcopyrite by metasomatism of the mixture, bornite in the next stage of transformation, and finally chalcocite; in other words, a series beginning with the ores poor in copper and ending with those rich in copper. During each replacement the solutions had to give up copper and take in sulphur. During this process there is not only a free circulation of the heavy-metal solutions in fissures and cavities, but there is also a permeation of large masses by solutions and the displacement of specifically lighter solutions by specifically denser.

Native Metals

The native metals with weak affinity for oxygen, constituting the second group, form especially fillings of cavities and occur as coatings on non-metallic minerals as well as on rocks that occur as gang material in the ore deposits. I have been unable so far to establish any instance of replacement of the host; the association with iron ore is, however, common, as this ore generally occurs on the boundary between the zones of oxidation and cementation.

The third group consists of mixtures of native metals with the normal heavy-metal sulphides, among which the commonest are gold with pyrite and silver with galena. For these also, I found in numerous thin sections only coatings and cavity fillings of the precious metals.

The last two observations concerning the absence of metasomatic processes are not to be taken that I deny the possibility of their occurrence; in any case, the evidence seems clearly to be that in these two groups metasomatism has not by far the importance it has in the genesis of the rich heavy-metal sulphides.

Origin of the Rich Secondary Sulphides by Descension

The principles of the origin of descending solutions of the heavy metals and their reduction by the primary metallic sulphides in the zone of cementation is today the common property of all economic geologists. The number of investigators who have concerned themselves with this question is too great for me to enumerate here. I will not neglect to point out, however, that de Launay belongs to the pioneers whose works have inspired my investigations, and that many a new path has been indicated by excellent learned men of this Continent. Nevertheless, the subject is far from exhausted.

I would like to discuss at this point the following questions that call for further explanation:

1. To what depths do such compounds occur?
 2. Of what importance are tectonic features?
 3. What is the influence of climate, denudation, etc.?
 4. How is their formation adjoining fissures at great depth to be explained?
1. General experience shows that oxidized ores

are formed as long as oxygen is present, and that the ores of cementation are formed somewhat lower down by reduction of the sulphides. As a rule, it is assumed that these transformations are brought about solely by solutions moving downward through open spaces, and it is customary, therefore, to regard the ground-water level as the lower limit of such transformations. Although oxygen is without question most essential for the production of oxidized ores, and its utilization precludes the further formation of such ores, the lower limit of the zone of cementation, on the other hand, is in need of revision. Not only circulating solutions, but also permeation play a rôle in ore deposits. Even if there are no large cavities in an orebody, circulation of the ground-water takes place, and the specifically lighter solutions are displaced by the specifically heavier. The solutions of heavy metals sinking through an orebody may therefore descend below the ground-water level, and may there, for example, produce metasomatic replacement of the primary ore.

Inasmuch as the displacement of a solution by a heavier one is a much slower process than circulation in open spaces, the ground-water level plays an important part in so far as it represents the lower limit of rapid alteration of the orebody which is being altered. It is not, however, the lower limit of alteration.

Tectonic Features

2. The tectonic features and ground-water level are intimately related; in fact, every structural dislocation causes a dislocation of the ground-water level. The dislocations may take place more or less rapidly. Secular elevation and depression cause slow but very considerable relative elevation and depression of the ground-water level; tectonic troughs and bursts usually bring about more rapid variations. The dislocations influence the open circulation of the solutions descending in ore deposits and thereby the minerals formed from them. Notable differences from normal phenomena can only be explained, however, when the tectonic features of a region have been thoroughly elucidated. It is, for example, of no avail to discuss the genesis of the rich silver ores of St. Andreasberg, which persist down to considerable depths, so long as it is impossible to determine whether the wedge lying between the two bounding shear zones—the tectonic block in which the silver veins all occur—is as a whole an elevated or depressed area. My conclusion is that the occurrence of cementation ores in depth points to depression; that the case is analogous to that at Butte, Montana.

3. The dependence of the secondary transfer of metals on denudation is generally recognized; the intensity of denudation determines the amount of oxidation and cementation ores. On the other hand, the differences in the development of the zone of oxidation due to climatic differences have not been adequately studied, as I have already pointed out. Careful investigations in this field would lead to important results, provided that genetically coeval deposits in different latitudes are compared in this respect.

Influence of Climate

As the intensity of denudation is determined by climate, these two factors can not be separated. The absence of notable oxidation processes at the Norwegian pyrite deposits, on the one hand, and the great development of gossan on the genetically coeval pyrite bodies of the Sierra Morena of Spain and Portugal, on the other, is not determined alone by the great difference in temperature, but in marked degree also by the difference in denudation. In Scandinavia glacial abrasion did not allow the accumulation of any large masses of oxidation products, whose development was further not favored by the low temperature; in Spain oxidation processes, favored by the higher temperature, have been but slowly disturbed by denudation.

4. The occurrence of typical oxidation and cementation ores in the primary zone has in particular instances aroused great interest. The occurrence of cementation ores in the primary zone is known to obtain where the secondary migration of metal has not yet progressed down to the ground-water level. Because of the changes of volume accompanying the cementation processes, fissures penetrating the primary ore are formed, along which the heavy-metal solutions descend; the cementation ores hence originate from descending solutions.

I have already alluded to the fact that cementation ores may form below the ground-water level, by the permeation of the primary ore and the concomitant displacement of the ground-water originally held by it. Investigations in Siegerland have shown that the new development of minerals need not take place in regular fashion, but may be localized in geochemically favorable situations. In this way are produced in the midst of unaltered material transformed masses without visible supply channels.

Oxidation and cementation ores may occur in systematic arrangement within fissures, which from some cause or other—commonly tectonic—have formed in the wall rock and have penetrated into the primary zone. The ground-water may be influenced in such a way by this fissure that the wall rock adjoining the fissure becomes dry. If subsequently meteoric waters penetrate the fissures to the dry zone, then their action will be like that of the atmospheric agencies. As long as oxygen is present, oxidation ores will form along both sides of the fissure and after depletion of the oxygen cementation ores will be produced at a somewhat greater distance. If the solutions were deficient in oxygen or carried heavy metals, then cementation ores alone would be formed. Processes of weathering can therefore take place under peculiarly favorable circumstances at considerable depth.

Origin of the Primary Ores of the Heavy Metals by Ascension

The studies concerning the metallogenetic type ores of the oxidation, cementation, and primary zones have considerably enlarged our knowledge of the occurrence of a great number of oxidized and sulphidized ores. A large number of laws are recognized that are not only important to science, but

which in practice are invaluable in the examination and valuation of ore deposits. As I have gone into this subject at another place, I will not occupy myself with the possibility of the formation of rich heavy-metal sulphides under such circumstances that they must be considered primary.

Genesis of Rich Sulphides

The generally recognized essential factors in the genesis of rich heavy-metal sulphides in the zone of cementation are heavy-metal solutions free of oxygen on the one hand and reducing normal sulphides on the other. According to present experience, the active solutions are descending solutions, but the direction of flow should be without influence on the process of the formation of the minerals.

In what cases of primary ore formation do the two conditions cited above obtain in ascending solutions? I know of but two, namely: (a) mineral solutions that are ascending in consequence of the reopening of a vein; (b) mineral solutions in fissures that intersect older veins or other orebodies carrying sulphides. The highly important vein intersections belong to the latter class. As in both cases younger heavy-metal solutions come in contact with older reducing sulphides, the generation of rich heavy-metal sulphides is to be expected, and it is known, for example, that the intersections of veins are commonly notable for the richness of their ore. If, however, the mineralization of whole districts whose veins are characterized by the reopening of the older fillings is examined more carefully, noteworthy discrepancies become apparent. The first filling of the veins of Siegerland and the Rhine region is, as a rule, siderite carrying a small quantity of pyrite; in a later stage of vein formation the siderite was commonly replaced by quartz, and subsequently both were replaced by galena and sphalerite. Although the galena of the Rhenish veins is argentiferous, I have never been able to find on the pyrite any cementation ore of silver, but only common galena such as is characteristic of the primary zone.

The Rhenish Schiefergebirge Veins

In some of the veins of the Rhenish Schiefergebirge copper-bearing solutions followed their reopening; pyrite was formed such as is common in the primary zone, but the rich copper ores typical of the zone of cementation such as bornite and gray copper are not to be found, although they are abundant in the zone of cementation of the Rhenish veins. The conditions prevailing during that process must, therefore, have been different from those obtaining during cementation. This calls for further investigation.

The second development of minerals at the intersection of veins unquestionably produces some ores that resemble those of the zone of cementation. The richness in silver of many of the Freiberg deposits at vein intersections and the increase of precious metal at the intersection of gold veins is well known. But even in these cases the ores, on the one hand, have not the features of those typical of the zone of cementation, and, on the other, there is a noteworthy massing of minerals at vein intersections

that are not characteristic of the zone of cementation, such as galena, sphalerite, pitchblende, etc.

A similar state of affairs obtains when heavy-metal solutions of deep-seated origin and carrying no free oxygen come in contact with other reducing ore-minerals. Nautan in Lapland, Grasslitz-Klingental in Bohemia-Saxony, are highly instructive examples. At Nautan, copper-bearing solutions penetrated beds carrying magnetite and deposited chalcopyrite; at Grasslitz the older metallic sulphides, especially the pyrrhotite, acted as precipitants upon younger copper-bearing solutions, so that chalcopyrite was formed as blebs and impregnations. Neither bornite nor chalcocite was produced by these ascending solutions.

Primary Bornite and Chalcocite

I come now to the question of whether primary bornite and chalcocite occur at all. In the literature there are found references to such deposits; for example, those of southern Norway and South Africa. In such matters, however, much depends on who was the investigator; the results can only command the fullest confidence when the geologist has had the necessary experience in the problems of metallogenetic type ores, one of the most difficult in economic geology. Even then, microscopical examination alone is insufficient; the examination in thin section is absolutely indispensable. In this way I found that a south Norwegian chalcocite, apparently massive, showed nuclei of bornite when examined in thin section; the proof was thereby furnished that chalcocite was at least not an original ore, but that it had developed from bornite. Concerning the genesis of the bornite, the investigation is not yet complete. In all the occurrences of bornite and chalcocite personally examined by me, which my colleagues reported as probably primary, I could in all cases demonstrate their secondary origin; I am therefore extremely skeptical concerning all statements of the primary occurrence of these rich copper sulphides.

The reason that ascending solutions deposit in general sulphides poorer in the heavy metals than do the descending, must be sought in the different geochemical conditions prevailing during ore deposition; ascending solutions are commonly under high pressure, have a high temperature, and are as a rule extremely dilute; descending solutions, in contrast, have approximately the average temperature of spring water, are under ordinary pressure, and, because in constant contact with heavy-metal compounds, are relatively concentrated. The three last conditions must be more favorable for the production of heavy metal sulphides than the first mentioned.

Value of the Examination of Thin Sections

The significance of investigations by means of thin sections and their importance in the determination not only of scientific but also of important practical matters, is apparent from the previous paragraph. The credit of first pointing out the value of the microscope in the study of ore deposits belongs without question to Beek. In the last years the microscope has been employed more

and more and is today an indispensable aid for the science of ore deposits. At present the examination by reflected as well as by transmitted light is inadequate; the diagnostic properties of the various ore minerals are known to but a limited circle of investigators. But it can already be surely foreseen that within a short time there will be elaborated a special petrography of ores which will build upon the methods employed in the microscopic investigation of rocks and metals.

Tube-Mill Liners at the Morro Velho Mill, Brazil

*The No. 6 Davidsen mill had extensive repairs, and new shells have been supplied to two others during the past fiscal year. On the whole, however, the plant has not been so troublesome as in previous years. The two new Chalmers & Williams mills arriving will be erected as soon as possible to do away with the old mills, which would otherwise have to undergo some extensive repairs if they were to continue working. The new mills are directly driven, and it is hoped they will show a considerable economy over the existing plant, which, it will be remembered, was nothing more than an experimental one. The fluted linings of manganese steel put in during December 1911, for the purpose of ascertaining if this hard but expensive metal would prove cheaper than the chilled iron cast locally, still appear to be in perfect condition. The wear has been exceedingly small, the ribs retaining their shape, which is not the case with the chilled metal, consequently the pebbles remain in place and the grinding effect of the moving stone is mainly borne by the pebbles and not by the metal. By appearance it would seem that the linings would last as long again as the period they have been working. Assuming this, the following comparison is possible: Manganese steel, life 952 days, costing 94c. per day, and chilled iron, life 289 days, costing \$1.82 per day.

This leaves little doubt that the manganese steel is the right metal for the linings, and in the case of the rock-crusher jaws the comparison is even more favorable, but used as dies for the stamps it has not done so well. Further experiments will, however, be tried. Hard rock for the mills is secured nearby, and occasionally contains gold.

Mining concessions held in Korea at the end of 1912 totaled 646 lode, and 278 placer properties. The value of the exports of mining products from the territory during 1912, according to the report of the Mining Bureau, of the Government was as follows: gold, \$4,689,285; silver, \$16,000; copper, \$1531; iron, \$155,221; graphite, \$82,309; coal, \$166,522; total \$5,110,868.

Coal shipments from Newcastle, New South Wales, Australia, during the first half of 1913 totaled 2,307,998 tons, valued at \$6,171,700. This is an increase of 89,396 tons and \$568,710 over the same period of 1912.

*Abstract from annual report of the St. John Del Rey Mining Company.

Metallurgical Tendencies in Western Australia

By W. A. MacLEOD

*The following remarks on the above subject are prompted by the recent criticism on Australian progress by H. T. Brett, who lately revisited Kalgoorlie after several years' absence.

Before touching descriptively on some of the recent installations, I will first record on technical matters generally a few scattered impressions tending to show a most healthy state of progress in gold milling in this state.

Power

Reviewing the different power plants, I notice three distinct stages in the development of this most important matter. In stage one are complete modern types of steam plant, with all the necessary auxiliaries; in stage two, the gas producer operating on charcoal fuel; and in stage three the gas producer operating on wood fuel. When I say—and all figures substantiate the statement—that the costs by this third system are nearly one-half of those by the first,

CONCENTRATE ROASTING AND VACUUM-FILTER PLANTS OF OROYA LINKS COMPANY, KALGOORLIE.

it must be admitted that here at least are symptoms of a healthy progress, and I take no risk in prophesying that the next few years will see further great strides in this same direction. The installation of producers burning the wood direct, without the intervention of the old type of charcoal kiln, has been a great step in advance from the power point of view. To those acquainted with Westralian conditions, the position will be fully appreciated when I say that the total cost for power (including fuel, water, wages, and all sundries), on a 6000-ton all-sliming plan basis, is now 22c. per ton.

Grinding

Following the ore in the process of treatment, I have some comment to make in connection with the grinding-pan section. Within the last three years the ordinary 5-ft. grinding pan, by the addition of the Freeman pipe-classifier evolved at the Great Fingall mill, has been so altered that it now occupies a unique position as a secondary crusher. This classifier automatically removes an even graded finely ground product, and admits of a great increase in feed of coarse crushed ore to the pan. Following the principles of stage crushing, this pan occupies most fittingly the position intermediate be-

tween the stamps and tube-mills. I am not attempting at present to define the exact scope of the pan as contrasted with the tube-mill, but simply wish to point out that in pan practice a decided advance has been made by the use of the classifier referred to.

Classification, Thickening, and Filtration

Two plants in Western Australia recently erected by Bewick, Moreing & Co. have been so designed that the sand is first removed from the pulp by cone classifiers, the overflowing slime being separated by mechanical thickeners, and the sand, after being continuously agitated, rejoins the slime, both being then treated together in the one vacuum vat. These plants are not all-sliming, but carry out in practically one operation the dual requirements of slime and sand treatment, thus marking a distinct step in advance in treatment methods, the whole of the attention being confined to one point, minimizing the cost of equipment and running costs necessary with separate sand and slime treatment when these are deemed advisable.

The mechanical thickener referred to replaces the extensive nests of spitzkasten and other settling tanks formerly used for settling the slime and obtaining a clear overflow. It achieves the same purpose as the Dorr mechanical thickener used in other countries, is of simple construction, and can deal with clayey ores which otherwise would be almost impossible to settle thoroughly. The adoption of the mechanical thickener results in a great saving of water, and permits of continuing slime treatment. There is considerable improvement in classification of pulp at a number of mills. These remarks apply to the Lake View and more particularly to the Oroya Links (old Oroya Brownhill) mills, where a perfect system of classification is in use, and where concentrating practice is carefully attended to in principle and detail.

An inspection of the different vacuum-filtration plants shows that during the past six or seven years many improvements have been made in this direction. The original type of stationary vacuum-filter has been improved into the present up-to-date gravity or pump-filling types of West Australian vacuum-filter; and, further, the most recent development evolved at the Great Boulder has been the perfecting of the automatic Ridgway machine, which is now being used on many mines with great success. With this plant it is impossible for a careless operator to discharge unfiltered pulp, and stoppages of the power plant do not cause loss of pulp and unwashed cakes. The power consumption is lower than formerly, and, perhaps most important of all, the soluble gold loss is reduced to a minimum.

Some Recent Westralian Plants

In his comments, Mr. Brett proceeds to outline roughly some of the recent installations in South Africa and Rhodesia. It will be interesting, therefore, to consider some of the more recent installations in Western Australia.

*Abstract from the *Kalgoorlie Miner*.

In dry crushing, the Great Boulder Perseverance plant may be taken as a model from many points of view, and today stands as a type of excellent practice in this direction. It is a pleasure to add that the dust trouble has been greatly minimized, formerly considered an inherent and necessary evil in such plants.

The Oroya Links

I have already mentioned the Oroya Links in connection with its classification system, and it also calls for comment on account of its low working costs, about \$3.84 per ton, which includes mining from a considerable depth in four distinct properties covering a longitudinal extent of nearly one mile.

Another most interesting example of advance in design of plant is that of the Victorious mine at Ora Banda, treating about 9000 tons per month at a cost of about \$2.52 per ton. This plant is gas driven, consists of five Huntington mills, and Ridgway filter plant of three units. The costs are the more noteworthy as the bulk of the ore is obtained from ordinary stoping operations, and not open-cutting.

At the Mountain Queen, Bewick, Moreing & Co. have erected a gas-driven plant with Holman stamps and West Australian type of vacuum-filter, treating 5000 tons per month. On this small tonnage working costs of \$3.36 per ton must be regarded as exceptionally low and indicative of great advance in methods of treatment. Here again the greatest part of the ore is obtained by stoping, the balance by open-cut work.

Quite recently the same firm has erected at the Queen of the Hills, Meekatharra, a similar type of plant, which, like that of the Mountain Queen, is of the combination type, treating sand and slime in the one vacuum unit.

As showing the great variety of practice, it is interesting to remark that the same firm, at the Yuanmi mine, installed a 20-stamp mill, all-sliming, with vacuum-filtration, the power plant being of the down-draught wood-gas type.

As another illustration in a different direction, I would refer to the Bullfinch plant, which is electrically driven. This plant consists of 20 stamps, tube-mills, and Ridgway filters.

Sons of Gwalia

Bewick, Moreing & Co. are now undertaking the remodeling of the Sons of Gwalia plant, with a capacity of 13,000 tons per month. The steam power plant for treatment is being entirely converted into down-draught wood-gas plant of the 'Commonwealth' type, and the method of treatment changed to all-sliming. This plant, when the alterations are completed, will typify the most recent advance in power and metallurgical practice.

The superintendent of the Gwalia Consolidated (under the management of the before-mentioned firm), has during the past six months been evolving a working plant for the extraction of gold by volatilization. The results of two-ton test samples were so satisfactory as to warrant the installation of a working unit, which is now complete, and it is anticipated that the results by the smaller test samples will soon be confirmed on the larger scale.

I think I have now adduced ample evidence to convince anyone who will take the least trouble to look into the matter that on comparing the gold-milling practice of seven years ago with that of today, many advances have taken place, and that the engineers responsible therefor have worthily upheld the status of the industry.

I was pleased to note in Mr. Brett's remarks that he referred to one mine in Rhodesia which was to be equipped with a large plant on West Australia lines, dry crushing, roasting, and cyaniding. I also noticed two references to installations of flotation processes, one referring particularly to the Minerals Separation. Although Mr. Brett's casual review of the position seems to have impressed him with the want of progress in gold mining generally, still it is gratifying to know that he evidently recognizes the advances made in Australia in flotation processes, of which Broken Hill is the home.

Mr. Brett mentions the case of the Shamva mine, a large low-grade property, worth \$4.80 per ton. The plant on this property, when complete, will treat 50,000 tons per month, or nearly 2000 tons per day, and the cost of mining and treatment he estimates at \$2 per ton. This at first sight appears, and no doubt is, excellent work, but it must be remembered that a similar property in Western Australia could be operated on practically the same figure, for we are already operating on tonnages of from 150 to 300 per day at a cost of \$2.40 to \$3.36 per ton.

Placer Mining in Siberia

The following interesting figures are taken from the last annual report of Lena Goldfields, Ltd., operating in Siberia:

During the fiscal year 1911-12 there was mined 549,244 cu. yd. of gravel averaging 9.486 dwt. per cubic yard, as against 861,438 cu. yd. averaging 10.002 dwt. in 1910-11. The total production of the different groups of claims worked, to October 1912,

is given as 4,411,163 oz., valued at \$79,584,000. In the Dogaldin property, 14 drill-holes were driven, and, according to the report of Charles M. Rolker, there is a gravel channel 210 ft. wide and 7 ft. deep, and may continue for 430,800 ft. in length. Reserves of gravel in a total stream length of 31,731 ft., in groups two and four, are 2,857,774 cu. yd., containing 1,162,945 oz. gold, which will leave a net profit of 266,031 oz. Costs in 1910-11 averaged \$6.10 per cubic yard. About 5000 men are employed at the Lena Goldfields at the present time.

A Good Fireplace

By J. D. HUBBARD

Many times, on my journeys, when enjoying the hospitality of some miner, I have been asked: "Do you know a plan for an open fireplace that won't smoke?" I do, and here it is.

There are some human comforts in common to all and within the reach of everyone, and an open fireplace is one of them. Back in 1906 I was a member of the good old Bachelors' Club of Goldfield in the days when hope ran high and Ananias was obliged to hide for shame. In the large and comfortable dining and living room of the Bach-

That fireplace grew upon us so that I sat down one day after lunch with Charlie and George Kaeding, and we made measurements and drawings of it. Since then I have built several according to this plan and they were all successful.

But, in using the plan, be not like Fletcher's Chinaman out in Korea. He (the Chinaman) was shown the plan and ordered to build the fireplace. "Uh-huh," he grunted, and then proceeded to insult that plan, or rather the plan passed out of his mind entirely and he proceeded to build as his forefathers. The blueprint had about as much significance to him as the vertical projection of Halley's comet. When Fletcher's nice new paper was all spoiled by the smudge arising from the first

FRONT ELEVATION.

SIDE ELEVATION.

clors' Club, when the last of the furnishings had been removed from that famous 'round table' to the domains of our most excellent cook, the 'grass' bachelors would gather around that famous fireplace, and with pipe and yarn pass a pleasant evening. Be it known there were two kinds of bachelors in that club. Some of them lived like comets, ate like ostriches, and slept like elephants, always fearful of 'missing something' on the street. They are nearly all dead now, I believe. But others of the type of placid 'Dad' Stewart were generally to be found around that fireplace in the evening. No matter if the wind blew from north, south, east, or west, that fireplace behaved itself, and only smoked from the top, which was right and proper. The original designer of the fireplace is unknown to me, but he knew his business.

'blowing in', he sought me and made sundry personal remarks. According to the Oriental mind, a fireplace is no good unless it smokes all over, and the 'Chink' was proud of his success. On investigation I saw what was wrong. I again referred to the plan and asked Fletcher if he thought the result was justified. Fletcher looked at the plan, at the fireplace, and then at the grinning Chink, who built worse than he knew. I had to stop up my ears—and never saw that same Chink again. He has probably hid somewhere out in the Gobi desert.

Stick to the plan and you will have a fireplace that will cheer the heart and make the old pipe taste better.

The metric system is now in use in the Dominican Republic.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Mining Schools and Politics

The Editor:

Sir—In a recent number of the *Mining and Scientific Press* I saw an editorial on the relation between state schools and politics, in the course of which you took occasion to quote the Governor of Colorado as finding fault with the absence of members of his party on the faculty of the School of Mines of Colorado. From what I have seen of Governor Ammons, I was convinced that you had done him an injustice, and I called the matter to his attention. I am just in receipt of the enclosed letter from his Secretary, and I trust you will see your way clear to at least retract the statement made. I believe the Governor is a sincere friend of this school, and is far above taking such a position as indicated by your statement.

CHARLES A. CHASE.

Boston, August 25.

The letter referred to follows:

"State of Colorado: Executive Office.

"Denver, August 18, 1913.

"Charles A. Chase.

"Dear Sir—The Governor asks me to thank you for your letter of August 16, enclosing the article from the *Mining and Scientific Press*. He made no such statement as is credited to him in this article. It would perhaps be well to have the impression this article conveys corrected. The Governor thanks you for your interest in the matter.

"C. W. FAIRCHILD."

[We were in error in attributing this statement to the present Governor and regret greatly the slip that imputed it to him. Our own statement was made on the faith of an eminent and well informed engineer, but it should have applied to Mr. Ammons' predecessor in the chair. We are glad to learn that the present Governor is a friend of the School of Mines, and we hope he will make his influence felt for the good of the institution.—EDITOR.]

Ore

The Editor:

Sir—T. A. Rickard has defined ore as "metal-bearing rock, which, at a given time and place, can be exploited at a profit." Let me set that down as an opening statement. Next let me call attention to the fact that Mr. Rickard is the editor of a book entitled 'A Guide to Technical Writing' in which precision of language is strongly advocated. We know that the controlling spirit of your valuable paper generally practises what he preaches. The reprint of his lecture on 'The Valuation of Mines' is really too good an opportunity to be allowed to pass unnoticed. (It is not often that we get a chance of putting one over on T. A.) Bearing in mind his definition of ore, are we to assume

that he is redundant in the second paragraph of his lecture, when he states that "we may define a mine as an excavation that yields profitable ore"?

In using the expression "profitable ore", Mr. Rickard is true to himself; he has used the correct expression to describe the commodity.

In the definition quoted above, he has joined forces with a great many other people who are assuredly trying to lay down a law which can never be accepted by the profession in general nor come into general use. The standard of profit is not the measure by which we know ore. The general acceptance of the term must always largely be governed by its geological significance, and while the question of profit does, and always will, enter into our use of the term, because all mining operations are carried on with a view to making a profit, at the same time, using the word in its commercial sense, we must remember that not all businesses are carried on at a profit, despite the desire to do so. There is no more reason why the word 'ore' should be limited by the temporary state of the 'profit and loss' account, any more than the commodities dealt in by the grocer, butcher, or other tradesman, should be limited in the same manner.

There is no gainsaying the fact that Mr. Rickard is one of the greatest exponents we have on the correct use of English, besides which he is a sturdy champion of the standard of profit-meaning for the word 'ore', and in the lecture above quoted, in several places he finds it necessary to qualify the term in a manner to make it intelligible.

His illustration of the ore at Earlston shows the impossibility of his making even himself clear by a striking adherence to his definition of the word 'ore.' The stuff at Earlston should be waste if his definition is right, but I submit that the substitution of the word 'waste' for 'ore', wherever it occurs in his description of the Earlston deposit, would leave most of his readers entirely in the dark as to what he was talking about.

At the top of page 769, he says: "The same ore in California or New Zealand on the basis of a correct sampling, would afford the making of a mine; in the desert of West Australia at that time it assured a first-class financial funeral."

There can be no doubt that if we continue to use the word 'ore' in the way we are in the habit of using it and the way Mr. Rickard has used it in 'The Valuation of Mines', and classify it as profitable, or unprofitable, as the case may be, no confusion can arise.

CHARLES S. HERZIG.

London, June 28.

The Editor:

Sir—Mr. Herzig's humor is not lost. To the serious side of his criticism I have this to say. The use of 'profitable' in connection with 'ore' is redundant to those who use the word in accordance with my definition, but all do not do so, and it is permissible to be redundant in the effort to be explicit. It is better to be redundant than to be misunderstood. In the definition of a mine as "an excavation that yields profitable ore," the word

profitable is also emphatic, in order to distinguish a mine from a hole in the ground which is fit for the last resting-place of a dead mule. By perversity and ingenuity combined it is possible to ridicule any definition. I challenge Mr. Herzig to proffer a definition of 'ore'; if he will, I can promise to make it look sheepish.

The significance of 'ore' is economic before it is geological. The idea of profitable exploitation is implicit; the gold in the sea does not make the ocean an ore deposit, simply because no means exists for extracting the metal profitably. It can be, and it has been, extracted unprofitably. As soon as a mineral aggregate or a metal-bearing rock is surmised to be exploitable, then it begins to resemble an ore; but it is only when that surmise takes form, in terms of time and place, that the geologic product assumes economic value.

T. A. RICKARD.

London, August 15.

Duty on Cyanide Salts

The Editor:

Sir—I have observed some effort being made in New York to create public sentiment in favor of the retention of a duty on sodium cyanide and potassium cyanide, which have been free-listed by the Senate in bill H. R. 3321.

Color is given to the view that there is an industry in the United States engaged in the manufacture of these materials which would be injured if the Senate proposals are carried out; but to the best of my knowledge there is no such industry, and if the figures as to the actual cyanide manufactured out of coal-tar residues in this country and its percentage compared with the amount of cyanide imported were given, I think the figures might prove enlightening. I am given to understand that large quantities of cyanide are imported in concentrated form and by the addition of common salt and other cheap and practically inert but allied materials, it is decreased in strength to a commercial strength of 0.98%, but this is not manufacture, it is merely 'doping.'

As viewed in the West, the effort to put sodium cyanide and potassium cyanide on the free list is welcomed for the reason that these chemicals are genuine raw materials, being used in one case in the generation of cyanogen gas for fumigating citrus fruit trees, and in the other case for gold recovery in mining. These are the two main uses of cyanide, and apart from these there is a small consumption in the arts, as, for instance, in plating work.

In considering the two main uses as above indicated, it must be admitted that these industries have genuine need for free raw materials. This is already conceded in the fruit-raising industry, as fertilizing materials of all sorts are admitted free, and there is no more reason for charging a duty on cyanide of potash than there is for charging it on muriate of potash, or nitrate of soda, both of which are on the free list at present.

As the citrus fruit-raising industry is facing a reduction in duty on its finished products, it can

well understand the placing on the free list of cyanide.

In the gold-mining industry, the case is even stronger for free raw materials. Inherently the protection of the gold producer is impossible, as the United States, in common with every civilized nation, puts no barrier upon the import of gold. Gold has a world value, and therefore the taxing by our Government of any and every raw material used in the winning of gold from the earth is just that much of a handicap upon the gold production of the United States. That this handicap is a serious matter may be shown by the statement that the present tax on sodium cyanide equals 4.47c. per pound, and a mine using 2.33 lb. of this material per ton of concentrate is paying a tax of 10.41c. per ton on each ton of ore treated, in addition to all its other taxes (corporation tax, state franchise tax, and others), and this in an industry which by its very nature cannot be protected.

Under these circumstances, I feel it can be demonstrated to the satisfaction of unbiased opinion that the action of the Senate in free-listing these materials is a wise one and worthy of support.

G. H. ATKINS.

San Francisco, August 14.

The Psychology of Zinc

The Editor:

Sir—The comments of R. G. Hall in the *Mining and Scientific Press* of August 16 are, without doubt, upholding to the present-day practice and improvements of zinc metallurgy, and subsequent working out of the more intricate zinc sulphide problems. After reading Mr. Clerc's letter in the *Mining and Scientific Press* of July 12, the casual reader feels somewhat depressed at the backwardness in zinc metallurgy in not utilizing the immense bodies of low and medium grade zinc-sulphide ores and in solving their metallurgical problem. Again, one is impressed with the fact that the real zinc metallurgist of today is a 'muscular' metallurgist, inasmuch as the different operations require personal skill in manipulation rather than technical skill.

As stated in various articles, the only available way open to the recovery of zinc is the fire-retort method, electric furnace and retort method, hydro-electric precipitation method, etc., each method being applied where the conditions of the ore and locality warrant it. Furthermore, for each of these different methods (with the exception, perhaps, of the electric furnace), the ore must be specially prepared before proper reduction to metallic zinc can be hoped for. Thus it is that the pre-treatment is most essential to ultimate success in the reduction. Each and every ore, due to its degree of complexity, requires special treatment, whether it be concentration by milling, flotation, magnetic separation, roasting, or leaching.

Most of the ores containing zinc are being mined and smelted, but the main sticker is the complex sulphide, 'black jack,' which is intimately associated with sulphides of iron, copper, lead, etc., and which will not lend itself to successful concentration and separation. Many processes have been tried on these

ores and failed. Fire, electric, and acid processes have been tried, and are being tried, with a certain degree of commercial success. Alkali processes also have been tried, but never to any great extent. Here is a field that is practically unknown upon a commercial basis. S. E. Bretherton, in an article on 'Smelting Zinc-Copper Ores' in the *Mining and Scientific Press* of April 12, describes a very promising alkali process, in which ammonia and carbon dioxide play the part of zinc solvents. The Afterthought (Shasta county) ore on which Mr. Bretherton comments, has, on a small scale, been successfully treated by this process for the removal of the greater percentage of the zinc in the ore. The cyanide process overshadows any acid process for the recovery of the precious metals, and why not an alkali process for the recovery of the zinc? It is a well known fact that zinc oxide, basic sulphate, and sulphate are soluble in ammonia and carbon dioxide. This is especially so when pressure is applied. With proper roasting, these conditions are brought about in the ore. In this process the final zinc product is a granular basic carbonate and hydrate, which when calcined gives an almost pure oxide suitable for pigment.

The field is indeed a large one, and with so many engineers working for improvements, one cannot help but agree with Mr. Hall that a successful solution of the problem of treating the troublesome zinc-sulphide ores will be attained at no far distant date.

FRANK L. WILSON.

Ingot, California, August 18.

Baffles

The Editor:

Sir—The letter of John E. Rothwell in your issue of August 2 appears to me an apt illustration of destructive rather than constructive criticism. His statement that I condemned baffles because I am connected with a "certain patented device in which the application would be expensive" comes perhaps inappropriately from an engineer who patented and placed on the market, several years ago, a thickener, the catalogue dealing with which promises "greatly enhanced settling effect produced by inclined baffles." The latter were expected, if my memory fails not, to multiply the capacity by three or better. Without raising the question of 'glass houses,' which will not interest your readers, I am sure you will agree with me that my statement, "In my opinion the principle involved of assisting settlement * * * by the use of baffles has given no practical results," is not a condemnation of a principle but an opinion as to certain facts.

I do not agree with Mr. Rothwell that it would be expensive to add baffles to the Dorr thickener, to which he refers, as I know that Mr. Dorr, being familiar with their trial at different places, had for some considerable time been seeking for positive information as to their value with a view to using them. Perhaps the best answer to his criticism is the fact that they were thoroughly tested on a Dorr thickener in South Africa, under the direction of Mr. Bosqui, and abandoned as of no value.

I think even Mr. Rothwell will not insist on call-

ing this test or the work done by the testing department of the Anaconda Copper Mining Co. in rectangular settling-tanks 'ignorant application.'

The work of the latter Company described in the valuable article by Mr. Hayden on 'Concentration of Slimes at Anaconda', in the August *Bulletin* of the American Institute of Mechanical Engineers, is most interesting, and Mr. Hayden, in his conclusion, summarized from the tests shown in table VI, states that "If perfect settling is required a baffle tank has no advantage; but if it is desired to slough off a portion of the solids, the baffle tank has a greater capacity," which may explain some of the discrepancies in the reports on the use of baffles.

My inspection of the tables given would suggest that they might bear a more optimistic interpretation, but I assume Mr. Hayden's judgment to be based on other observations as well.

I note Mr. Rothwell states that he has found baffles of marked benefit in settling-tanks, and feel that detailed data from him will certainly be appreciated, not only by myself, but by all other metallurgists; for I am sure that everyone realizes that, in the long run, whatever is of real value will be adopted.

I realize, too, that many an engineer satisfied with the theoretical correctness of a method has kept working on it, in spite of discouragements, until all difficulties have been overcome, and improvements of great benefit have thus been given to the world.

Without professing special knowledge in the settling line, I might say that there are likely to be many principles involved in continuous settling on a large scale that do not apply to the inclined baffle tests, convincing as they may appear at first sight.

H. N. SPICER.

Denver, Colorado, September 3.

Professional Ethics

The Editor:

Sir—Professional ethics have been discussed repeatedly in your columns; it would be interesting to hear the opinion of your readers on a contingency which may occur any day in the career of a mining engineer.

An engineer makes a thorough and extensive examination of a mining property for client 'A.' On receipt of the report, client 'A' decides not to take up the property. After a certain time, client 'B' asks the same engineer to examine the same mine, probably unaware of the examination already made. What shall the engineer do?

He cannot give to 'B' the report made for 'A', because the report belongs to 'A'.

Client 'A' may refuse to give 'B' the report, or may even refuse to sell it.

The conditions at the mine have not substantially changed since the examination was made.

To go over the mine again and write an identical report would be a bluff. To do the whole work over again (sampling excepted) would be like comparing a letter with its carbon copy.

What shall the engineer do?

G. CAETANI.

San Francisco, August 13.

Special Correspondence

LONDON

DECREASE IN TIN CONTENT OF ORE FROM THE DOLCOATH AND CARN BREA & TINCROFT MINES; DETAILS OF THE HALF-YEAR'S WORK.

The big tin mines in Cornwall are passing through a period of unusual low-grade ore, and I have previously referred to the steady decrease in the content at East Pool and South Crofty mines. At the present time it is Dolcoath and Carn Brea & Tincroft that are giving lower outputs; the latter is, in fact, in an alarming position, and not for the first time during its life. It is thirteen years ago since this old group of mines was taken in hand by a company organized under limited-liability law. In those days the yield of tin concentrate was 31 lb. per ton of ore. The grade has gradually dropped until during the past half-year it was only 19 lb. Most of the time, losses have been made on the operations, but during the two periods of high price for the metal, 1906-7, and the past two years, the balance has been on the right side. A dividend of 10% on the 'priority' shares was paid in 1907, and a similar amount for 1912. It will be remembered that two years ago the directors decided to import a high-priced engineer of proved experience in other parts of the world, in order to make an attempt to reorganize the plant and the methods of working, and Edward S. King was accordingly appointed to the position of gen-

ORENVILLE MINE, SURFACE BUILDINGS.

eral manager. He was able to effect many improvements and economies, and much of the money thereby saved was put back into the mine. Lord Clifden, one of the ground landlords, and a large shareholder, came forward through his agent, John Gilbert, a member of the board, and undertook to provide capital at a low rate of interest in order to equip the mines with an up-to-date dressing plant. Under these circumstances, it is distinctly unfortunate that the grade of ore mined should continue to decrease. The financial result for the first half of 1913 has been a loss; 45,537 tons of ore raised yielded 391 tons of concentrate, selling for £48,009, or at the average price of £123 per ton. During the previous half-year, 48,055 tons yielded 455 tons, selling for £57,078, or at the average price of £125 per ton. The loss was £2785, as compared with a profit of £6736. Already the directors, with the exception of Mr. Gilbert, are beginning to become restive, and are doubting their sagacity in making the great change of two years ago. They now allege that, when they engaged Mr. King, they expected to obtain his entire services and his continuous attendance at the mine, and they grumble that the resident manager has been changed more than once by Mr. King during the short period he has been in control. Mr. King has, of course, done much work in Cornwall these two years in addition to that at Carn Brea & Tincroft. It is also obvious that changes in management during periods of special development underground

and on the surface are highly inadvisable in general principles. But from my own point of view, these grumblings are not justified, and they would not have arisen had Fortune been more gracious.

The yield per ton at Dolcoath during the first half of 1913 has also been a 'lowest on record', having arrived at the point at which Carn Brea & Tincroft started. The exact figure was 30.23 lb. tin concentrate per ton, as compared with 32.09, 36.73, 41.23, and 47.38 lb. during the preceding half-years. The descent has therefore been steady and regular. The tonnage raised and treated was 58,304 as compared with 60,631 during the latter half of 1912, and the yield of concentrate was 786 tons as compared with 868 tons. The total receipts were £106,982, as compared with £118,481, and the net profit £32,061, as compared with £46,569. The so-called 'net profit' is not the same as 'distributable profit', as £4919 had to be written off for depreciation of plant. The shareholders received £17,500, being at the rate of 5% for the half-year. As I mentioned in my last letter, the directors and manager of Dolcoath have become alarmed at the poor results obtained from the main lode at depth, namely, from the 3000 to the 3300-ft. level, and attention has therefore been paid to other lodes in the property that have of recent years been neglected. A cross-cut was driven from the 1260-ft. level to explore the South lode, which is supposed to be a continuation of the lodes worked at East Pool and South Crofty. The lode has been cut, and is reported to be of good grade, but no information is given as to the nature of the ore found. If it is the continuation of the lodes mentioned, it will probably contain a much larger amount of wolfram and pyrite. But, as I said in my last letter, the public does not get much information from the Dolcoath company, and will have to wait until the meeting of shareholders, on which occasion another dribble of news will be vouchsafed in an indefinite sort of way.

NEW YORK

COPPER PRICES AND FUTURE INCREASE.—MESSINA, BOLEO, AND PITTSMTONT PROPERTIES.—HALF-YEARLY REPORT OF THE AMERICAN SMELTING & REFINING COMPANY.

Copper advanced to 16½c. per pound by the end of last week. That figure was named on September 4 by the Amalgamated, and the other agencies followed suit, the equivalent price being quoted in London. Sellers report a good demand, and predictions are freely made that prices will advance to considerably higher figures before the end of the year. In London copper was bought freely in order to make the shares of copper mining companies advance, but the fact that speculative sales were too great in proportion to spot transactions was too evident, and the price of shares went down instead of up. In New York Amalgamated only advanced about half a point during the week. The foreign visible supply on September 1 was given as 26,536 tons in England, France, and afloat, and 7538 tons at Hamburg and Bremen. This shows a decrease of 610 tons since August 15. Exports of copper from this country for the week ended September 4 are given as 5344 tons, or double the rate for the same period last year.

The Messina, the Transvaal copper mine, in which the Camp Bird is interested, reports that it produced 543.78 tons of copper during the quarter ended June 30. There was milled 5960 tons, and the concentrate produced contained 32.5% copper. The first reverberatory furnace is now ready to start and the second should be ready in a few weeks. The railway is expected to reach the mine early in October, and by that time all the plant will be ready. An important copper mine of which little is ever heard is the Boleo, in Lower California, which is closely held in France, and after the French custom, its operations are shrouded in mystery. The report for last year has appeared in France and discloses the fact that 360,000 tons of ore averaging 3.51% copper was smelted last year, yielding 28,336,000 lb. copper, with a net operating profit of \$1,414,024. The Company is controlled by the Rothschilds of Paris and the Banque Miraband. The matte and black copper produced is shipped directly to Europe.

The retiring of \$263,000 worth of the 6% bonds of the Pittsmont Copper Co. draws attention to the highly creditable manner in which the East Butte, under the management of Oscar Rohn, is pulling itself out of the trouble caused by the former management. The Pittsmont took over the Pittsburg & Montana, which was originally capitalized at \$30,000,000, assuming responsibility for the \$2,500,000 bonds issued by that Company. It then arranged with the East Butte C. M. Co. in 1909 to exchange the physical property, provided the East Butte would issue \$3,000,000 worth of stock to acquire 83% of the Pittsmont stock; the Pittsmont owning 90% of the Pittsburg & Montana. In this way the East Butte became responsible for the bonds and has now paid off \$1,000,000 of them. Under the present management the plant has been rebuilt without ceasing operations, development work has been pushed underground, and the Company is making a net profit of \$100,000 per month. The East Butte has about \$700,000 in cash assets, so that in little more than a half-year it will be free of debt.

The American Smelting & Refining Co. and the American Smelters Securities Co. have issued their half-yearly reports, covering the period to June 30, which shows that the gross income for that period was \$6,671,611, as compared with \$7,587,942 for the same period in 1912. This decrease in gross earnings is explained by Daniel Guggenheim, president of the two companies, as coming from the unsettled conditions in Mexico and the strike at the Company's El Paso plant.

The net income, however, on account of decreased charges, shows a decrease of only \$250,406 over the corresponding six months last year, being \$5,027,894, as against \$5,278,300 on June 30, 1912. This sum added to the previous profit and loss surplus leaves a profit and loss gross surplus of \$21,787,296, as compared with \$18,978,026, a gain of \$2,809,269. After deducting total dividends of \$4,010,000 on the common and preferred stocks, the profit and loss surplus on June 30, 1913, was \$17,777,296, as compared with \$14,968,026 on June 30, 1912, an increase of \$2,809,269. The Company has expended in the last six months in connection with new properties or increased facilities \$1,683,594 and has charged to depreciation the sum of \$558,200. The property account therefore shows an increase of \$1,095,753. The assets of the Company on June 30, 1913, are given as \$189,880,705, as compared with \$189,211,705 on June 30, 1912. The balance of \$2,063,894 left after paying dividends on the preferred stock of the Company was equal to 4.50% earned on the \$50,000,000 common stock, against 4.76% on the same stock for the corresponding six months of the previous year.

Morton Lexow, son of the late Clarence Lexow, is suing his father's law partners, George MacKellar and T. Tilston Wells, for considerable sums. Mrs. Lexow is a shareholder in the United Copper Co., and MacKellar & Wells are attorneys for Maurice Deiches, who has brought suit to have that Company declared insolvent. In a way too complicated to explain here, this is regarded as an attempt to prevent Mrs. Lexow from realizing anything from the wreck, and the incident is only of importance as illustrating the amount of collateral litigation to which such a fiasco gives rise.

PORCUPINE, ONTARIO

HOLLINGER AND DOME MILL EXTENSIONS.—DOME LAKE CO.'S AFFAIRS.—KIRKLAND LAKE DISTRICT.—CROWN RESERVE AND MCKINLEY-DARRAGH DIVIDENDS REDUCED.—WEST SHINING TREE DISTRICT.

It is understood that the Hollinger company is contemplating the installation of an additional 40 stamps, but it is believed that a great deal more development work is necessary before such an increase will be justified. The Dominion Bridge Co. has been awarded the contract for the steel work for the Dome Mines Co.'s mill, and this is being pushed to completion as rapidly as possible.

At the annual meeting of the Dome Lake Co., which was held at Toronto recently, three by-laws were submitted to the shareholders for their approval: (1) to increase

the capital stock by 250,000 shares; (2) to issue 100,000 shares at a discount; (3) to increase the number of directors from five to seven. After considerable discussion, only the first by-law was passed. At the meeting, the shareholders found that the Company had pressing debts of \$15,000 and total liabilities of \$160,000. The management was severely criticized for not placing before the shareholders a full statement of the financial affairs and of the physical condition of the mine. Another meeting is to be held shortly, when it is expected that the shareholders will receive full details of the Company's position.

Several minor deals have recently been made in the Kirkland Lake district, but as a whole things are quiet and not much work is being done. At the Tough-Oakes, formerly known as the Foster, driving is being carried on from the 100 and 200-ft. levels, and satisfactory results are being obtained. It is understood, however, that the recent issue of stock was rather a failure. On the Burnside property, adjoining the Tough-Oakes, the main shaft has reached a depth of 80 ft. and a cross-cut has been started to cut the vein which dipped out of the shaft at a depth of 50 ft. The Burr-Cartwright Syndicate is stated to be obtaining excellent results on the Wright-Hargraves property, on which it recently took an option, but has thrown up the option on the Hunton property, which is only a short distance from the Wright-Hargraves. The Hudson Bay Co. has also given up its option on the claims which were being worked in the vicinity of Kirkland Lake, a recent discovery of high-grade ore is reported from the Gravelle property, which lies a short distance south of the Teck-Hughes.

During the past few weeks, two of the large Cobalt mining companies have cut their dividend payments. Early in the month the Crown Reserve, which has been paying 2% regular and a 3% bonus per month, or at the rate of 60% per year, dropped the bonuses and is now paying at the rate of 24% per year. The reason for this action was on account of the earnings for the present year having fallen so far below the expectations of the Company, due principally to the unfavorable developments met with in the Carson vein, where the high-grade ore changed to barren calcite. Exploration work in other parts of the property has also been disappointing and has not resulted in the discovery of any new orebodies. The action of the directors in cutting the dividend was foreshadowed by the heavy liquidation of the stock previous to the announcement, and a good deal of dissatisfaction has been expressed by the shareholders on account of the advance knowledge gained by those who sold stock.

The second company to cut its dividend is the McKinley-Darragh, which has been paying at the rate of 3% regular and 7% bonus quarterly. In the future, the Company will pay at the rate of 3% regular and 3% bonus, or 24% per year. The reason assigned is that on account of the extensive development program being carried on at the McKinley and Savage mines and on account of the large sums being spent on the concentrator, the cash reserve had been reduced to a lower figure than the directors thought advisable. While the yearly disbursement may be increased by the payment of extra bonuses at the discretion of the directors, there is no intimation that the Company may return to the old rate of dividend. In contrast with the Crown Reserve, it is pleasing to note that there was no advance information of the action of the directors and there was no liquidation of the stock previous to the announcement.

Shareholders in the Temiskaming Mining Co. have been expressing dissatisfaction with the directors for failing to declare the dividend at the recent quarterly period. It is stated that the Company has a credit balance of over \$166,000, and the quarterly payment calls for only \$75,000. The last dividend was paid on April 30. Following the sale of the Northern Customs Concentrator to the English syndicate controlling the Cobalt Townsite Mines, the Northern Customs company has started work on a new mill which will be situated on the T. & N. O. railway on the other side of the La Rose Extension property. An order for

80 stamps has been placed, which is said to be the largest single order for stamps ever given in Canada.

Men associated with the Buffalo Mines Co., of Cobalt, have taken over the Ribble Jephson properties in the West Shining Tree district. At the present time they are working 40 men and expect to increase this force in the near future. They claim to have opened on the surface an ore-shoot 200 ft. long and running between 10 and 20 ft. in width, which will average over \$12 per ton. The work being done by this syndicate has caused some excitement, and a number of prospectors are going into the country which was staked during the summer of 1911. In the majority of cases the veins are too small and the average content too low to hold out much hope for successful operations.

JOHANNESBURG, TRANSVAAL

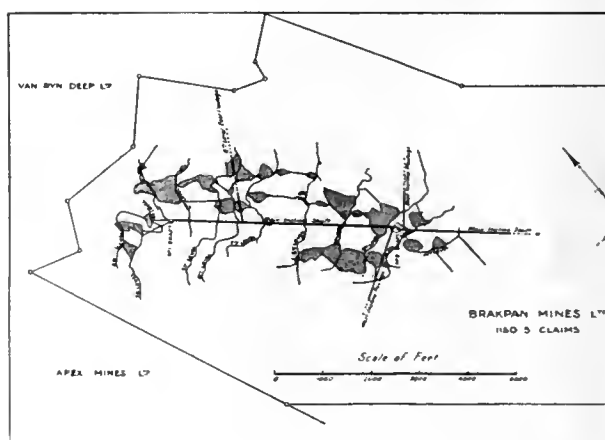

THE AFTERMATH OF THE STRIKE, AND NEW DEMANDS MADE.
—THE BRAKPAN MINE AND MILL RESULTS.

The principal topic of interest here is still the threatened general strike, but the centre of attraction has been transferred from the mines to the railways. It will be recollected that the general strike of the miners with the object of showing sympathy with the New Kleinfontein men was provisionally terminated by the intervention of the Government undertaking to deal with the grievances and to deal with the strike-breakers at the New Kleinfontein mine in a satisfactory manner. The strike-breakers have been awarded twelve months' wages by the Government, while a formidable list of reforms by the Miners' Association has been handed in to the Government for their early consideration. These demands include a minimum wage of 60c. per hour for surface mechanics, and \$6 per day minimum wage for drill-sharpeners, and a minimum wage of one-half the above rates for unskilled workers. The Association also suggests payment at increased rates for overtime and Sunday labor where unavoidable, but asks that Sunday labor at the mines, and particularly at the ore reduction works be abolished. Weekly payment of wages in place of monthly paydays are also asked for. All the above demands are absolutely new, and were never as much as mentioned during the recent strike, so that there is little probability of such demands being granted. The fact is that at the time of the strike no grievances were advanced, and at the present time there is no general or genuine demand for the above reforms. With regard to the eight-hour day from bank to bank, in place of the existing eight hours' work per day at the face, that was somewhat prominent during the New Kleinfontein strike; in all probability it will be brought up for consideration at the next session of Parliament at Cape Town. Notwithstanding the fact that the majority of the grievances now put forward for consideration by the Miners' Association are now heard of for the first time, and in most cases have not the support of the miners, there is considerable uneasiness on the Rand, due to the possibility of the miners coming out on strike with the object of supporting the railway men. The railway employees appear to have some grievances against the Government, but the latter is showing a disposition favorably to consider the removal of these, and in all probability a general strike will be averted.

The threat of a general strike throughout South Africa has during the week been withdrawn by the Federation of Trades Unions owing to the opposition met in so many quarters and the fact that the scheme was an impossible one at best. With regard to the extravagant demands put forth by the federation on behalf of the miners, they have been successful in obtaining the following concessions: A recognized allowance of half an hour for getting the white employees to and from the working places; ten days' holiday per year on half pay; a month's notice to be given to vacate the miners' dwellings; weekly payments of wages to men engaged by the day; and consolidation of the sick and benefit societies. The only real concession obtained by the men is that of ten days' holiday per year on half pay after twelve months'

continuous service underground and two years' continuous service on the surface, to take effect from July 8, 1913. Generally speaking, the long list of grievances was referred to the Transvaal Government, the minimum wage and other questions likely to add to the cost of working the mines being refused acceptance by the employers. Now that the question of a general strike has been abandoned, and the demands of the miners cut down to the above concessions, it is anticipated that work on the mines will be continued without any further interruption, as the employers have intimated that the above concessions are the utmost they are prepared to grant.

Among the different gold mines on the Rand, few have attracted so much attention lately as the Brakpan property, situated on what is known as the far eastern section of the Witwatersrand. The nominal capital of the Brakpan Mines Co. is £750,000, and the excellent results obtained in the early stages of milling, followed by encouraging reports, caused the £1 shares to rise to £4 10s. each. Results obtained from this property did much to rehabilitate this section of the Witwatersrand in the good opinion of stockholders, and even today the Far Eastern Rand continues to be more favorably regarded than the Western Rand or even the Germiston and Boksburg areas. Later reports from the property have not, however, maintained the excellent reputation previously earned, for not only has development been unsatisfactory, but deep-mining difficulties in the early stages of operations have caused a serious setback in the profits. It has long been recognized

PLAN OF BRAKPAN UNDERGROUND WORKINGS.

that in this part of the Rand unprofitable areas alternate with profitable areas, and it seems doubtful whether, if taken on the whole, more than 50% of the total area under existing conditions can be regarded as profitable. Studying the June quarter at the Brakpan, it is seen that out of 4365 ft. of development on the 'reef', less than 2000 ft. is shown by sampling to be in profitable areas, while the assay value only averaged 5.7 dwt. per ton over a width of 32 in., as compared with 7.8 dwt. over a width of 37 in. during the previous quarter.

At the end of the last financial year the entire developed profitable ore reserves were reported as averaging 6.74 dwt. over a width of 61 in., while in 1912 the averages published were 9.36 dwt. over a width of 37.7 in. In the face of these assays those obtained in the June quarter were distinctly disappointing, especially when it is remembered that selective development, as well as selective mining, is carried on as far as possible at the Brakpan mines. In regard to actual working results, the position at the Brakpan property is even worse, for during the last six months the working costs have been increased from \$4.16 to \$4.44 per ton, while the monthly tonnage milled has fallen from 59,130 to 53,000 tons, and the profits in June to \$129,000 as compared with \$187,000 in January. These results can scarcely be considered creditable to a mine starting off so well as did the Brakpan, and the present administration is paying dearly for the mistakes made in the pioneer management of the concern. The Company is, however, gaining experience in the difficul-

ties attending mining on the Rand at a depth of 4000 ft. from the surface. That serious subsidences would occur on this property was long ago recognized by many engineers outside the management.

SALT LAKE CITY, UTAH

NEW MILL AT TINTIC AND MINE DEVELOPMENTS.—SILVER KING CONSOLIDATED AND AMERICAN FLAO AT PARK CITY.—THE STARLESS AT BINGHAM.—MONTANA-BINGHAM TUNNEL.

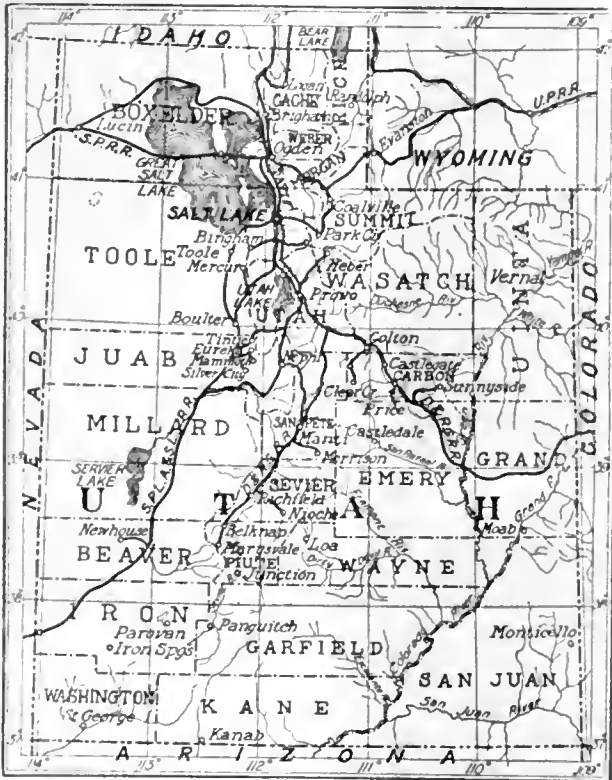

The Knight mines at Tintic are being operated at a slow rate pending the completion of the Knight-Christensen chlorination mill. The machinery for the mill is all under cover, and the plant will be ready for regular service about October 1. The first unit will have a capacity of 100 tons, and provision has been made for the addition of four more units as needed. N. C. Christensen, the designer, estimates the treatment cost at \$3 per ton. A drift driven into the porphyry on the 800-ft. level of the Dragon Consolidated to procure water for the Knight mill has obtained a flow of 20 gal. per minute. Iron sulphide showing in the face of the drift indicates higher mineralization than has yet been found.

The Chief Consolidated has gone to a heavy expense

The American Flag is making separate shipments of high and low-grade ore from its new east vein, which runs almost parallel to the Ontario fissure. The low-grade ore, averaging about \$22 per ton, lies between streaks of chloride and galena that average from \$90 to \$110 in gold, silver, and lead. Rough separation is accomplished by dumping the cars on a grizzly sloping down to a bench. The low-grade ore, which goes through the grizzly, falls into a chute and goes in with the high grade. The coarser material is hand sorted from the bench. Before this improvement was adopted the high-grade ore was picked from the vein before blasting. Occurrence of galena boulders imbedded in Ontario chlorides seems to establish the priority of the Silver King, or galena, ore deposition at Park City, as compared with the Ontario ore. The American Flag apparently has the overlapping of the two zones.

The Starless property, at Bingham, is being thoroughly sampled for its owner, E. A. Wall. Fifty samples, Mr. Wall says, average between 1 and 2% copper, with small amounts of gold and silver. The Starless is on the zone of disseminated copper developed by the Utah Copper Co. It has been opened by a 2000-ft. tunnel and development covers 6000 ft. As the owner has never approved of Utah Copper milling methods, it is likely that an entirely different system will be adopted at the Starless. The property will be within easy reach of the new Montana-Bingham tunnel. The low-grade copper ore of the Starless is estimated at several million tons. The Montana-Bingham tunnel has proceeded 2000 ft., gaining 1200 ft. vertical depth. In 1000 ft. it will gain a maximum depth of 1500 ft. It has passed through 300 ft. of porphyry containing low copper percentages and is now in quartzite. Some low cost records have been made in driving this tunnel. The American Smelting & Refining Co. is spending \$250,000 at its Garfield plant on improvements. These include a 350-ft. stack.

The new two-compartment shaft of the Moscow, in the Star district, Beaver county, is down 60 ft. Machinery from the old shaft has been placed on the new one to hasten the work. The new shaft was started to save the expense of horizontal development. The Nellie, a group of eight claims, is a new Beaver county shipper, having marketed a car of \$33 ore. Jens Neilson and Charles Olsen, the owners, expect to ship two cars per month.

MAP OF UTAH.

in adopting the Bisbee system of stope filling. The system was decided upon after the occurrence of a fatal accident. While the filling was in progress the output was reduced materially, but development continued and resulted in the opening of a large lens of ore on the 1200-ft. level. The Victoria Consolidated company has opened a large body of low-grade but profitable ore on its 1000-ft. level. The ore is rich in gold on the 1200-ft. level, recent shipments netting over \$2000 per car.

At Park City, J. A. McIlwee, who is sinking the Silver King Consolidated shaft from the 1300 to the 1800-ft. level under contract, recently sunk the three-compartment shaft 75 ft. in 18 days, timbering all the way. At the 1700-ft. level a station 14 ft. wide, 14 ft. high, and 20 ft. long has been cut. The contract will be completed by the middle of October, and the Company will proceed with the development of the ore that was cut in sinking the shaft. Mr. McIlwee is employing 65 men on contract development at the Daly-Judge mine. A car of smelting ore shipped last week by the Thompson-Quincy brought the Company \$635 net. The ore was saved during development work.

KALGOORLIE, WESTERN AUSTRALIA

The total gold returns for June were \$2,410,200, the chief producers being as follows:

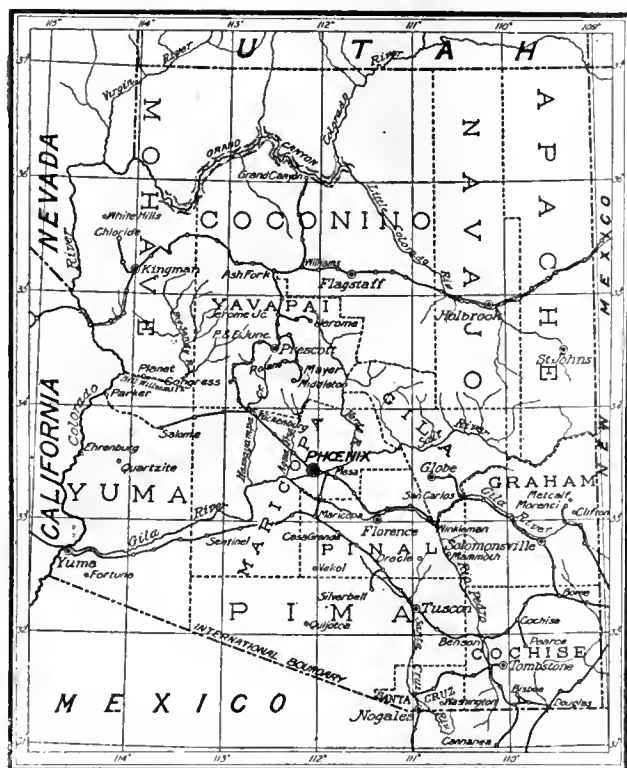

Name.	Tonnage.	Value.	Profit.	Dividend.
Great Boulder	16,457	\$220,700	\$115,100	\$328,100

General Mining News

ARIZONA

COCHISE COUNTY

At the Commonwealth mine, at Pearce, a great deal of mine development has been done and new equipment erected, including the new mill. A new three-compartment incline shaft, 5 by 17 ft., has been sunk. The ore from this mine is fairly low grade and oxidized down to and below water-level. It contains little sulphide minerals and no concentrating machinery will be required in the mill for the ore at present developed, according to the *Bisbee Daily Review*. It occurs in large bodies in more or less regular shoots in both the andesite and breccia formations, but as a rule these are in close proximity to the contact of these rocks. It is planned to mine the ore with the shrinkage-stope method. The new shaft equipment consists of an Allis-Chalmers electric slow-speed mine hoist, steel head-frame, three-ton ore skips, and double-deck man-cages for handling the men. The new mill and power-plant consist of the following equipment; crusher building, one No. 6 and two No. 4 Gates gyratory crush-

MAP OF ARIZONA.

ers, revolving-trommel, and inclined-belt conveyor up to the mill ore-bins. In the main building are thirty 1550-lb. stamps, arranged for coarse stamping; three 8-ft. Hardinge conical tube-mills; three standard tube-mills; 6 Dorr thickening tanks, four of them being 42 ft. diam. and the other two 38 ft. diam., and all 12 ft. high; four 18-ft. face by 11-ft. diam. Oliver filters; two Merrill clarifying filter-presses, with a combined capacity of 1500 tons of solution per day. In the precipitation building are two Merrill precipitating presses, combined capacity 1500 tons of solution per day; steam-drying pans; two Donaldson melting furnaces. The power-plant contains one cross-compound Allis-Chalmers heavy-duty Corliss engine, operated, condensing, direct connected to one 750-kw., 3-phase, 450-volt generator with exciter; surface condenser; vortex vacuum pump; centrifugal circulating pump, and enclosed engine; steam-driven duplex pump; open type water heater; two duplex plunger feed pumps; vertical steam separator; automatic exhaust valve, and a four-panel switchboard complete.

About 100 men are employed. Edgar A. Collins is superintendent and B. H. Bosqui metallurgist. The Montana-Tonopah Mining Co. controls this property.

GILA COUNTY

(Special Correspondence.)—At the Miami mill, the Deister Machine Co.'s experiments with its new sand and slime tables are showing favorable returns in assays of concentrate. As the machines concentrate four times the amount of ore handled by the old type of tables and occupy little more than half as much space as the table now being used, their use should extend greatly.

Miami, September 5.

The Inspiration Consolidated Copper Co., at Miami, will add to its electrical equipment two 75-hp., one 100-hp., and two 150-hp. motors and panels recently ordered from the General Electric Company.

At the Iron Cap the face of the main east drift continues in copper ore averaging 9%. At No. 3 stope, above the drift where the high-grade streak was strongest, the ore assays 22% copper, 10% iron, and 10 or 12 oz. silver. No. 2 and 3 stopes are being extended to connect. The raise recently started on the 800-ft. level is improving, now averaging 6% copper, 20% iron, and very little silica. It is four sets, or about 20 ft., high. The ore shipments to El Paso average a carload every second day.

PIMA COUNTY

The Columbia mine, in the Comobabi mountains, in the southwestern part of the county, is shipping 6000 tons of gold-silver-copper ore from Tucson to the El Paso smelter. The property is owned by Vassar, Pellet, Mrs. McKay, H. H. Huffman, and others.

YAVAPAI COUNTY

It is probable that the Climax Mining Co. will construct two large dams across the Hassayampa river to insure a reliable supply of water for the mill, which is situated on the river. Shortage of water has resulted in the plant being shut down for several weeks this summer.

The Rainy Day group, in the Copper Basin district, is now showing 4½ ft. of mineralized schist in an adit driven 300 ft. at a depth of 225 ft. from the surface. A vein of talc also contains \$12 per ton in gold. In another claim Louis La Barr has opened 3½ ft. of ore assaying \$12 per ton in copper and gold.

CALIFORNIA

AMADOR COUNTY

(Special Correspondence.)—At the Plymouth Consolidated mine, sinking is now in progress from the 1850-ft. level. At 2000 ft. a cross-cut will be driven to the vein to pick up the ore-shoots developed above. On the 1850-ft. level the main shoot was found to be 380 ft. long.

Plymouth, September 6.

The management of the Hardenburg mine is considering sinking the shaft 200 to 300 ft. deeper, and it is likely that the stockholders will be asked to authorize this work at their next meeting. The Company has opened a large tonnage of milling quartz in the upper portion of the mine, and is keeping the 20-stamp mill working at full capacity.

About 400 men are employed at the South Eureka, and the property is one of the greatest supports of the district. The Company is disbursing regular monthly dividends and increasing its treasury surplus. The work in the lower levels is proving encouraging, and the bulk of ore for the 80-stamp mill is coming from below the 2000-ft. level. The Company is also developing the Oneida mine, where 20 stamps are running steadily on good ore. The work of connecting the Oneida and South Eureka by means of drifts is proceeding rapidly, and will be completed within a short time. William H. Schmal is superintendent of both properties.

INYO COUNTY

The Wancoba Mining & Milling Co. was incorporated on July 30 under the laws of Arizona. The claims are 23 miles east from Big Pine, and 3 miles from the Saline valley road. That region is well mineralized, and the owners of the group believe they have prospects justifying extensive development. A large body of wolfram has been opened in the foothills west of Bishop, and analyses are

being made at San Francisco, Los Angeles, and Boulder, Colorado.

NEVADA COUNTY

Good progress is being made in building a power-plant and 10-stamp mill at the Arctic mine, while sufficient ore is developed to insure operation of the plant for some years. The Company has been greatly handicapped in the past by lack of power, and the plant now under construction will clear this difficulty. It will be operated by water power and the facilities are sufficient to keep the machinery in action at all seasons of the year.

PLACER COUNTY

On September 8, fire destroyed \$60,000 worth of buildings and plant at the Southern Cross mine, in Humbug cañon, on the American river.

SHASTA COUNTY

(Special Correspondence.)—The Balaklala Copper Co. made a trial test of the Hall desulphurizing plant last week, and expects to commence treatment of ore on a commercial scale about September 3. One of the four roasting furnaces has been equipped with hearths and fittings for the treatment. Gas generated from crude oil is introduced into the oven, and a temperature of 700 to 900°C. maintained. The sulphur is then passed through a Field washer and precipitated in tanks. H. F. Wierum, assisted by R. E. Scott, has charge of the tests. One hundred men are on the payroll, and regular shipments of ore are being made from mine to smelter. Heavy shipments of silicious ore are being made to the Mammoth smelter daily from the Reid mine at Whitehouse, Old Diggings district. The Shasta Dredging Co. is preparing to further prospect the gravel deposits on the Saeltzer and adjoining ranches near Redding. The drill records of a former examining company have been secured. It is stated by one of the owners that the gravel averages 25c. per cubic yard, with streaks ranging from 50c. to \$5.

Redding, September 1.

The Farmers' Protective Association has decided to raise \$10,000 for the purpose of defraying the expenses of a campaign to protect the rights of the farmers against the smelters at Kennett and Coram. In spite of the importance of such an undertaking, there were only 30 present of the 200 members of the Association, and it will require other meetings to formulate the lines along which the organization will proceed. One member stated that, although the Balaklala Copper Co. had invited the Association to visit the Coram plant, it was more likely that an expert would be employed. Evidently from the steps taken at the above meeting, the Association does not seem satisfied by the Hall process being installed at Coram, seemingly condemning the device before even an inspection as to its installation is made, let alone a test run for the treatment of ore.

The first 400 ft. of the shaft at the Gladstone mine, French Gulch, is to be retimbered and a new hoist is to be installed. The hoisting engine will cost between \$15,000 and \$20,000. With the new and more powerful engine the Gladstone will be worked to a still greater depth. The shaft is sunk at the inner end of an adit 4000 ft. long.

SIERRA COUNTY

A total of 118 stamps are now crushing ore in this county, as follows: Alaska mine, Pike City, 40 stamps; Alleghany district mines: Tightner, 10 stamps; Croesus (Plumbago), 20 stamps; El Dorado (Fessler), 10 stamps; Two Counties (Gold Canyon), 5 stamps; and Bear Creek, 3 stamps; total stamps in Alleghany district proper, 48; Sierra Buttes, Sierra City, 20 stamps; and Swastika, 10 stamps. All are making regular shipments of bullion, with periodical consignments of high-grade concentrate to smelters. The number of stamps will be increased before winter arrives by the starting of several mills, now idle, at Sierra City, when the fall rains have replenished the water-supply.

SISKIYOU COUNTY

The Patterson Creek Gold Mining Co., owners of the Queen of Sheba mine, has paid off the men and closed permanently. The Sheba has produced many thousands of

dollars in gold in the past, but during the last two years has been an unprofitable investment.

COLORADO

CLEAR CREEK COUNTY

(Special Correspondence.)—A body of ore 25 in. wide and worth \$40 per ton has been opened in the Lucky Boy workings up Spring gulch. The discovery was made by H. J. Theide & Co., who are operating under lease. It is announced that work will be resumed in a few days on the Bertha property, situated on Seaton mountain. It is proposed to remodel the mill that is on Virginia street in this city. W. L. Shaffer is manager.

The French Flag property, on Seaton mountain, has been secured under lease by Charles S. Ridley, of Denver. Work was started yesterday and shipments of mill ore will be started next week. The product will be sent to the Combination mill. Assays return from \$6 to \$19 per ton in gold. Telluride men have taken over the Sun and Moon mine, one of the former heavy producers of this district. Operations will be carried on through the Newhouse adit.

A streak of ore 8 in. wide has been found in the drift being driven on the Centennial vein, which is worked by the Two Kings M. Co. Assay tests show 1.5 oz. gold and 14 oz. silver per ton. A. A. Warren is manager.

Williams and Traylor, leasing on the Freeland Extension mine at Freeland, made a carload shipment of ore a few days ago that returned 1.35 oz. gold, 17 oz. silver, and 20% lead. On an average of 20 tons of mill ore is being shipped per day from the Seaton mine. Consignments are made to the Combination, Jackson, and Newton mills. E. D. Payne is manager. A 6-in. streak of ore has been opened at the Onelda mine at Freeland that is worth \$200 per ton in gold and silver. Shipments of mill ore have been going out for some time, the product being consigned to the Combination mill. Owen & Rogers are operating under lease.

Idaho Springs, August 29.

SAN MIGUEL COUNTY

The Junta Consolidated Gold Mining Co., at Telluride, will install three 100-kva. transformers and 50-hp., 75-hp., and seven 20-hp. motors recently ordered from the General Electric Co. The Smuggler-Union Mining Co. has also ordered a 4-ton electric mining locomotive from the same company.

TELLER COUNTY (CRIPPLE CREEK)

The suit commenced by the Portland Gold Mining Co. against the British corporation, Stratton's Independence, Ltd., to recover \$300,000 damages for ores alleged to have been wrongfully mined by the defendant Company from the territory of the Portland company on Battle mountain, has been settled by 'stipulation.'

A brief supporting the United States Government's contention that it has the right to collect the sum of \$4883 from the Stratton estate as a war tax has been filed in the United States District Court in Denver, by Henry E. Lutz, assistant United States district attorney. The claim to this amount arises from the sale of the Independence mine on Battle mountain by the late W. S. Stratton to an English syndicate through Verner Z. Reed, then a resident of Colorado Springs, who held an option on the property. During August the El Paso company shipped 89 cars or 3250 tons, and lessees 33 cars of ore. Eight mines of the United Gold Mines Co. operated by lessees were on the producing list of that corporation in August, and a total production of 33 cars estimated of a tonnage content of 1000 tons resulted. In addition, 1165 tons of low-grade ore was treated at the Wild Horse mill.

Measurements taken early in September by T. R. Countryman, representing the Cripple Creek Deep Drainage & Tunnel Co., of the flow from the Roosevelt deep drainage tunnel, gave results of 6275 gal. per minute. A comparison with the flow measurement of the corresponding period last year shows a falling off and decrease of 3725 gal. per minute, the gauge last September at this time recording 10,000 gal. per minute. The Vindicator mine produced 65 cars of ore on company account and 35 cars by lessees in August. The 1600-ft. level is opening well.

IDAHO

LEMHI COUNTY

The geology and ore deposits of this county are described in U. S. Geological Survey Bulletin 528, by Joseph B. Umpleby. This county, situated in the east-central part of Idaho, has until recently been difficult of access. With the extension of the railroad to Salmon in 1910, mining activity in parts of the area took on new life. Placer gold was discovered at Leesburg in 1866, and soon thereafter lode deposits were recognized. Lead-silver deposits were worked actively in the eighties, but not until the advent of the railroad did this industry reach its maximum importance. The total production of the county is about \$20,000,000, two-thirds of which has come from gold, three-fourths of the remainder from lead, about \$40,000 from copper, and the rest from silver. The basement rock is a gneissoid granite of Archean age which outcrops in the northwestern part of the area. Unconformably above it is a thick and widespread series of Algonkian schists, slates, and quartzites. The ore deposits of the county may be grouped as gold placers and lodes, lead-silver veins, and tabular replacements, copper-bearing gold veins, cobalt-nickel deposits, and tungsten-bearing veins. Sixty-three mineral species are recognized in the ores of Lemhi county. The outlook for a steady growth in the mining industry of the county is bright. A large tonnage of base gold ore remains. Placers are now being worked by dredges, which are converting into an asset ground heretofore valueless for mineral. The annual production of lead-silver has increased greatly since the advent of the railroad and seems destined to become the most important in the county. Tungsten will probably become an asset, but the future of cobalt and nickel is more uncertain.

SHOSHONE COUNTY

It is reported that about 20 ft. of high-grade copper ore has been opened in an adit at the North Fork mine, 22 miles above Prichard. The Marsh Mining Co., operating the Marsh mine near Burke, has made another acquisition by purchasing the control of the Poorman Extension Mining Co., one of the pioneer corporations of the Coeur d'Alene, its charter having been issued in 1886. The holdings consist of the Green Mountain, Fuller, Burke, Clark Fraction, and Fir Fraction, all of which adjoin the original Marsh group on the north and the Poorman property on the east. The five claims include approximately 45 acres. Acquisition of the Poorman Extension properties, together with the Got-Em-Now claim, recently purchased from Patrick Clark, gives the Marsh company control of 130 acres, patented, including a part of the town of Burke, lying on both sides of Canyon creek. The portal of the Marsh main working adit is on the Green Mountain claim, an easement for the adit having been secured several years ago, and the purchase of the Poorman Extension ground gives the Marsh surface rights much needed in operation. It is stated that the long adit being driven from the Humming Bird ground into the Hercules, to cut the latter's orebodies at approximately 800 ft. below the present No. 4 adit level will be completed about March 1, 1914, as the work is progressing now at the rate of 250 ft. per month. The adit will be about 8000 ft. long and will provide underground facilities permitting Hercules ores to be delivered direct to the railway by gravity.

MICHIGAN

Houghton County

The Calumet & Hecla company is now sending over 2000 tons of ore that is coming from the stopes to the mills daily, and operations are being increased. Other mines in the district, the Champion, Quincy, Isle Royle, and Superior, have resumed production, and it is hoped a few short weeks at the most may see conditions again normal in the district.

MONTANA

Granite County

(Special Correspondence.)—Rich ore has recently been opened in the property of the Gold Hill Mining Co. at

Maxville. R. B. Hoffman is superintendent. J. P. Raines of Butte is interested in the property.

Maxville, September 5.

(Special Correspondence.)—The Swastika Mining Co., at Phillipsburg, is preparing to equip its mine with electrically generated compressed air. Commercial ore has been developed containing silver and copper.

Phillipsburg, September 1.

JEFFERSON COUNTY

(Special Correspondence.)—A promising body of silver-copper-lead ore has been opened in the 1200-ft. adit of the Ironside property. This mine is on the head of Little Boulder river, 15 miles north of Butte.

Butte, September 1.

LEWIS AND CLARK COUNTY

(Special Correspondence.)—A rich development is reported from Marysville. William Smigaj, an old prospector, claims to have uncovered from two to four feet of ore assaying 200 oz. silver and \$20 gold per ton. His claim lies near the Whip-Poor-Will ridge between Gloster and Empire.

The Butte & Minnesota Mining Co. has exercised its options on some claims on Wolf creek, 9 miles from the Great Northern railway. The ore contains gold, copper, and silver. It is planned to build a mill this fall. There is considerable activity in the Scratch Gravel hills, north of Helena. The Copper-Silver Montana Mining Co. has been doing considerable development work. Profitable ore containing gold, silver, copper, and lead has been opened in the shaft while sinking between the 400 and 500-ft. levels. The vein is in granite, the copper occurring as tetrahedrite. The shaft is only 600 ft. from the Great Northern railway and a few miles from the East Helena smelter of the American Smelting & Refining Company.

Helena, September 1.

SILVERBOW COUNTY

The Tuolumne Copper Mining Co. reports as follows for the year up to July 31:

Ore mined, tons	22,875
Copper, per cent	3.99
Ore smelted, tons	22,395
Metal production:	
Copper, pounds	1,310,569
Gold, ounces	92
Silver, ounces	46,858
Revenue from metals sold	\$133,819
Balance from December 31, 1912, etc.....	204,679
Total revenue	\$338,498
Mining and development	100,950
Equipment and general expenses	40,967

Total expenditure	\$141,917
Dividends	160,000
Cash on hand	34,509
Accounts receivable	2,072

The new surface equipment at the Belmont mine of the Anaconda Copper Mining Co. is about ready for use. Steel bins of 2000 tons capacity have been built and a steel trestle connects the bin with the hoisting shaft.

NEVADA

ESMERALDA COUNTY

(Special Correspondence.)—The Dams Coal Mining Co., operating three miles from the Tonopah & Goldfield railroad near Coaldale, reports that the drill has gone through four veins of coal, and a contract has just been let to sink a two-compartment shaft to 400-ft. depth. Work started on August 14, and early in November the coal is estimated to be opened. An analysis made at Goldfield shows the following: Moisture, 1.80%; volatile matter, 32.60; fixed carbon, 50.60; and ash, 15 per cent.

Coaldale, September 6.

Preliminary estimates of the Goldfield Consolidated's August operations are as follows: Ore treated, tons, 32,119; gross value, \$389,000; profit, \$194,000. The tonnage treated would have beaten the previous high record, had not oper-

ations been interfered with by storms which shut off the power. Costs totaled \$6.10 per ton.

HUMBOLDT COUNTY

The National Mines Co. has cut a larger body of high-grade ore than ever in No. 5 and 6 levels. This is encouraging to the owners of the property. The Company is driving south on the rich vein, and at the same time is sinking the shaft to a lower level to cut the rich vein.

The Charleston National Mining Co. has nearly completed the installing of the large hoisting plant. This is one of the finest pieces of machinery in the camp, and will enable the Company to sink to a great depth. It is reported that Mr. Stowe intends sinking a large working shaft or incline in the foot-wall of the vein similar to that of the National Mines Co.'s large shaft. High-grade ore is being taken from the vein to the north of the workings in the Company's mine.

NYE COUNTY

(Special Correspondence.)—Tonopah has had a trying time with electric storms, and this week the heaviest rainfall in this county which has been recorded, drowned out the water works at Rye Patch. This kept all of the mining companies busy hauling water and pumping it from different sources in order to keep the mills running, but the only mill that really suffered was the Belmont, which was compelled to stop 30 stamps for about two days. The water-supply of Tonopah was described in the *Mining and Scientific Press* of December 14, 1912.

Tonopah, September 4.

PROPERTY OF THE DARMS COAL MINING CO.

At Manhattan, a consolidation of the Manhattan Mustang and Jumping Jack Merger Mines Co. is now under way, the latter property including the Jumping Jack, Indian Camp, and Stray Dog claims. All of these have produced a good deal of ore and are in the schist belt.

STOREY COUNTY

At the Labor Day sports at Virginia City, Mike Grivic and Pat Hughes, Comstockers, won the drilling match, driving a hole 42½ in., and Berry and Trabucca were second with 39 in. to their credit in the 15 minutes allotted.

UTAH

JUAB COUNTY

With the satisfactory ranges assumed once more by the spelter market, the May Day, Uncle Sam Consolidated, and Lower Mammoth companies have resumed the extraction of zinc ores for the market. James C. Dick, the general manager, returned from these properties on September 1, and when asked in regard to the permanence of these shipments, he said it was more a question of the spelter market than anything else, for in all these mines, and the May Day in particular, there is a large tonnage awaiting attention from the management. The zinc ores find a ready market in the Middle West.

PIUTE COUNTY

It is stated that H. F. Campbell, of New York City, and C. H. McDowell, of Chicago, secured from the State Land Board surrender of the state's right to a section of land 12 miles from Marysville in the southern part of the state, said to contain valuable deposits of alunite.

SALT LAKE COUNTY

The Alta Tunnel & Transportation Co. has decided to continue driving its tunnel throughout the winter, and special precautions are being taken to prevent snowslides damaging the property. On one day during the first week in September the Utah Copper Co. sent 29,000 tons of ore from Bingham to the mills at Garfield.

SUMMIT COUNTY

From May 28 to August 21, the American Flag mine at Park City has produced the following metals: gold, 245 oz.; silver, 14,625 oz.; lead, 107,067 lb.; copper, 1982 pounds.

WASHINGTON

FERRY COUNTY

The smelters at Greenwood, Grand Forks, and Trail, British Columbia, require more silicious ores, and there is a market for over 5000 tons per month from Republic mines, if they can supply this quantity.

STEVENS COUNTY

The transmission line from Colville to the United Copper mine at Chewelah, 28 miles, has been completed, and the transformers are being installed and connections made with the four motors, of a combined capacity of 265 hp.

The new 125-ton mill will be ready to operate in a few days. The working force will be increased from 85 to 110 men. A shipment of 282 tons of ore from the Silver Standard mine, near Hazelton, to the Trail smelter returned \$106.32 per ton. Both the Erie and Harris mines, in this district, have sent rich ore to the smelter. The adit being driven by the Portland Canal Tunnels, Ltd., is in near 1850 feet.

CANADA

BRITISH COLUMBIA

The report of the Granby Consolidated Mining, Smelting & Power Co. for August shows that 101,722 tons of ore was treated, of which 99,641 tons came from the Company's properties and 2081 tons was custom ore. During the month the Grand Forks smelter made and shipped 1,827,300 lb. of blister copper. During the eight months of the current year there has been smelted 829,070 tons of ore, of which 820,240 tons was from the Company's properties, while 8830 tons was custom ore. During the same period there was made and shipped 14,492,997 lb. of blister copper.

(Special Correspondence.)—Shipments of ore from Kootenai and Boundary mines to the Trail smelter last week totaled 6454 tons, making a total for the year to date of 241,527 tons. In the Slocan district the principal shippers were the Standard, 74 tons, and the Utica, 30 tons. The No. 1, at Ainsworth, shipped 141 tons, and the Silver Hoard, in the same camp, sent out 48 tons. In the Nelson district the heaviest producer was the Yankee Girl, at Ymir, which shipped 131 tons. Production of the Kootenai districts shipped to Trail was: Nelson, week 1165 tons, year 52,831; Lardeau, year 332 tons; Rossland, week 5661 tons, year 165,432; East Kootenai, week 378 tons, year 24,604; and Slocan and Ainsworth, week 3022 tons, year 131,142. Spokane, Washington, September 6.

ONTARIO

During the week ended August 30, five mines shipped 252 tons of ore and four mines shipped 143,916 oz. silver bullion. Since this date the Nipissing and Buffalo companies shipped 135,128 and 66,694 oz., respectively.

The drift between No. 6 and 16 shafts, on the 360-ft. level at the O'Brien mine, connected the two shafts last week, and preparations are being made to sink on No. 6

vein. A winze will be sunk 50 or 75 ft. and another level opened. A 6 by 16-ft. tube-mill and three Deister tables are being added to the O'Brien mill. A new system adopted some months ago which has given perfect satisfaction at the mill is that of a submerged screen for the stamps. The screen is an invention of M. R. Shannesy, of the mine, and can be used under as much as 18 in. of water. Its efficiency is noted in the discharge giving an increased tonnage and improves the wearing conditions of the dies. It also prevents choking. The pumps are working on the drainage of Kerr lake, and will continue until the beginning of December, the date estimated for the completion of the job.

Schools and Societies

The MONTANA STATE SCHOOL OF MINES, at Butte, began the school year on September 2, under favorable circumstances. The faculty has been strengthened by the addition of Bancroft Gore to the chair of metallurgy. Mr. Gore is a Harvard graduate with many years practical metallurgical experience in Montana and South America. The school is in better condition than ever in its history, and the mill is in first-class working order under the direct supervision of a practical millman. The mineralogical and geological museum has been expanded and systematized so that it now compares favorably with others. The local practising engineers are taking an increasingly active interest in the school and its students.

Beginning this fall, HARVARD UNIVERSITY and the MASSACHUSETTS INSTITUTE OF TECHNOLOGY are to maintain in coöperation a School for Public Health Officers. The facilities of both institutions are to be available to students in the school, and the certificate of public health is to be signed by both A. L. Lowell and R. C. MacLaurin, presidents of the respective universities. The object of the school is to prepare young men for public health work, especially to fit them to occupy administrative and executive positions such as health officers or members of boards of health, as well as secretaries, agents, and inspectors of health organizations. The requirements for admission are such that graduates of colleges, or technical and scientific schools, who have received adequate instruction in physics, chemistry, biology, and French or German, may be admitted to the school. The medical degree is not in any way a prerequisite for admission.

The AMERICAN MINE SAFETY ASSOCIATION will meet on September 22, 23, and 24, at Pittsburgh, and a large attendance is expected from distant mining states. An interesting program of papers and discussions has been prepared, and arrangements have been made to visit points of interest in and about Pittsburgh. J. W. Paul, of the U. S. Bureau of Mines, reports that the arrangements for the mine-rescue contest, which will be held at Arsenal Park on September 22, assures the success of this unusual event. Handsome prizes have been offered by the Draeger Oxygen Apparatus and Hirsch Electric Mine Lamp companies, and the American Mine Safety Association, for the men who compete in showing their skill in doing rescue and recovery work at mines. At the same time there will be held a first-aid contest somewhat similar to those held elsewhere in the mining regions. For this a number of handsome prizes have also been received, notably from Johnson & Johnson, a first-aid cabinet and also a first-aid instruction outfit; from Bauer & Black, a first-aid cabinet; American Red Cross, a set of medals; and the American Mine Safety Association, a set of medals for the individual contestants. Many entries have been made. The Bureau of Mines has arranged a big experimental explosion at its mine at Bruceton. This will be the first explosion exhibit given at the mine since its completion. It is expected to attract unusual attention. Altogether, those in charge of the affair feel confident that this will be one of the biggest and most important meetings of persons interested in coal-mining held at Pittsburgh, excepting, possibly, only the National Demonstration held two years ago.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

C. S. HERZIG has gone to Tulsa, Oklahoma.
L. J. PEPPERBERG has returned from Wyoming.
S. W. PARK has been in San Francisco this week.
F. J. LORING will be in California early in October.
P. R. BRADLEY was in Plumas county over Sunday.
SIDNEY J. JENNINGS was in Salt Lake City recently.
B. B. THAYER has returned to New York from Butte.
G. W. CRANE will spend about a year in the Tintic district, Utah.

RUSH M. HESS has returned to Guayaquil, Ecuador, from Telluride, Colorado.

ROSS B. HOFFMANN has returned from Alaska and is now at Carmel-by-the-Sea.

F. L. RANSOME was in San Francisco Monday, and has gone to the Yosemite.

EDWIN J. COLLINS, of Duluth, was in Denver last week on professional business.

EDWARD CLARK, who has been spending the summer in California, was in San Francisco last week.

J. S. DILLER, who has been making geological surveys in Trinity county, will be in San Francisco shortly.

FRANCIS P. BRAY, who has been spending two months in Australia, is returning to London by way of Manila, China, Japan, and across Siberia.

F. C. LINCOLN has left the University of Illinois to accept a position with the Bolivian Development & Exploration Co., of which H. G. Knowles is the head.

ARTHUR W. BURGREN, engineer of the Matehuala unit of the American Smelting & Refining Co., of Matehuala, San Luis Potosi, Mexico, is at Oakland, California.

EDWARD H. BENJAMIN has severed his active connection with the Joshua Hendy Iron Works, and will resume his former practice as consulting mining engineer.

BRADLEY STOUTON was guest of the local members of the American Institute of Mining Engineers at San Francisco on Friday of last week, and was entertained by the Los Angeles members Thursday of this week.

The present address is wanted of WAYNE CHOATE, a mining engineer who several years ago represented English investors in this country, mainly in New Mexico. He was last heard from at Detroit, Michigan. He is cousin to RUFUS CHOATE, formerly ambassador from the United States to England. Kindly communicate with this office.

Obituary

HENRY BARRIOULET KAEDING, who died in Los Angeles, California, June 12, from heart trouble, was born in San Francisco in 1877. He was the son of one of San Francisco's pioneer business men, and his early education was obtained in the public schools. His technical education was, with the exception of a year at the California School of Mechanical Arts, and a few months with Frank Green, then city chemist, obtained through personal study. After four years in the lode mines of Amador county, and a year in the placer mines of Plumas county, he made an extended trip, in 1896, to the South Pacific islands in a small schooner, exploring the Galapagos, Guadaloupe, and other islands, and making extensive collections of the flora and fauna for the Smithsonian Institution. He was an authority on Western ornithology. In 1898 he went to Korea for the newly organized Oriental Consolidated Mining Co. and was one of the first to successfully treat concentrate by cyanidation at a time when little was known about this branch of cyanidation. He had charge of properties in Mexico and for two years was in charge of the Siempre Viva Mining Co. of Nicaragua. He was a frequent contributor to the *Mining and Scientific Press* and other scientific papers, and was a member of the American Institute of Mining Engineers, the California Academy of Sciences, the Cooper Ornithological Club, and other scientific societies.

EASTERN METAL MARKETS

(By wire from New York.)

NEW YORK, September 11.—Copper market is strong and a large business is being done both at home and abroad. European trade prospects are much brighter and supplies are being imported at a heavy rate from America. It is to be expected that as the price of copper goes up, the consumers will be more reserved, but the fear of a temporary scarcity in supply is expected to maintain the demand. The lead and spelter markets remain quiet. Spot to November copper is quoted at 16½. Lead is quoted at \$4.70 and spelter at from \$5.85 to \$5.95. Spot tin is quoted at from \$42.25 to \$42.50. General advance is to be noted in copper stocks.

SILVER

May	60.88	60.21	Nov.	62.73
June	61.29	59.03	Dec.	63.38

The features of the silver market remain unaltered, according to Pixley & Abell, on August 23. Throughout the week China has sent moderate buying orders, and, as offerings have been under normal, the present rates have been easily held. The Indian bazaars also have given a little support by buying for the September settlement steamer leaving London next week. Bombay stocks were reported on August 19 to be 3000 bars, and it is possible that a little more may be required for this settlement.

LEAD

Lead is quoted in cents per pound or dollars per hundred pounds, New York delivery.

QUICKSILVER

The primary market for quicksilver is San Francisco, California, being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the car-load can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

Week ending	Aug. 28.....	40

AUGUST ON STOCK EXCHANGE

Business on the New York Stock Exchange for the month of August was a little more active than in July, but below August of last year. Total sales this year amounts to 6,102,350 shares, against 8,946,165 last year. The largest day's trading was 537,815 shares on the 12th, and the smallest 160,219 shares on the 25th of the month.

Bond transactions were far below the previous month and a year ago, sales amounting to only \$29,539,000. The largest day's business was \$1,912,000 on the 12th, and the smallest \$917,000 on the 20th, according to the *Evening Post*. The month's total sales compare as follows with previous months and with August in other years:

STOCKS, SHARES

STANDARD OIL DIVIDENDS

The *Financial World* comments as follows: "In figuring the total amount of dividends that will be paid this year by the various former subsidiaries, 30 odd in number, of the Standard Oil Co., it is calculated that shareholders will receive in round figures the sum of \$100,000,000. The sum might be a million or two above or a million or two under the \$100,000,000 mark, but it will not be far from it either way. The old capital stock of the Standard Oil Co., before the trust was broken up, was \$100,000,000, so that this year's dividends will represent about 100% return on the old capital. For the third quarter of the year the total disbursements will be about \$15,000,000, making for the eight months this year thus far paid about \$86,500,000. The fourth quarter will increase this to the \$100,000,000 mark. In 1912 cash dividends paid totaled only \$2,000,000, but since then there have been various increases and additional stock distributed, while in March last the Standard Oil of New Jersey paid a 40% dividend amounting to nearly \$40,000,000. There is a probability also that next spring the New Jersey company will pay another dividend that will be classed as extra and large. The Standard Oil subsidiaries are doing the cream of the oil business, and their dividends are creamy also. No skimmed milk there."

Money coined at the mints of the United States in August was as follows.		
Denomination.	Pieces.	Value.
Dimes	2,300,000	\$230,000
One-cent pieces	19,145,000	191,450
For Philippine Islands:		
20-centavo pieces	205,000	P41,000
The unfilled orders of the United States Steel Corporation on August 31 totaled 5,223,468 tons, a decrease of 175,588 tons over July. On July 31 there were 5,399,356 tons, and on June 30, 5,807,377 tons.		

Book Reviews

BRITISH COLUMBIA. Report of the Minister of Mines for 1912. Compiled by W. F. Robertson. P. 350. Ill., index.

The period under review in this work has been the most productive in the history of British Columbia mining. The statistical data and general survey of the industry are presented in a most interesting manner. The various districts are discussed in an authoritative way, which together with the illustrations and figures presented form a composite treatise on the mining industry of that country which is not to be had in any other work on the subject. The scope and progress made in mining during the past year may be judged by the output figures, which show an increase from \$23,499,999 in 1911 to \$32,440,000 in 1912.

ELECTRICITY IN MINING. By Siemens Brothers Dynamo Works, Ltd. P. 201. Ill., index. Charles Griffin & Co., Ltd., London. For sale by the *Mining and Scientific Press*. Price \$3.50.

The application of electricity to mining is becoming more general every year, and today electrical equipment is to be had for the driving of every machine used in or about a mining property. Electricity has been found as a most useful form of power in the driving of every class of machine from the most insignificant pump to the largest of mine hoists, and in most cases it has been found to be superior to either steam or compressed air. In the work under review it has been the purpose of the authors to present a work indicating the various purposes to which electricity can be applied in mining work and to give a general idea as to the design and lay-out of such installations. Among the subjects discussed are included distribution systems, power stations, switch gear in generating stations, power transmission, electric winding engines, pumping plants, mine fans, compressors, haulage systems, locomotives, auxiliary machines, rock-drills, signaling systems, and shot firing. While the work cannot be regarded as a textbook on the subject of electricity applied to mining and is largely descriptive of the application of the products of the Siemens company to mining operations, the splendid illustrations and diagrams are of interest, and, with the discussion, present a general idea as to what well equipped plants are like and the broad application of electricity to mining operations.

ELECTRICAL ENGINEERING FOR MECHANICAL ENGINEERS. By H. J. S. Heather. P. 324. Ill., index. D. Van Nostrand Co., London. For sale by the *Mining and Scientific Press*. Price \$3.50.

This work comprises a series of lectures which were written by the author for a special class of men on the Rand, who found themselves confronted by peculiar circumstances. The men were the resident mechanical engineers of that district and had to deal with the problem of a change in the power-supply for the mines from steam to electricity. Previous to 1908, electricity had been used only to a small extent in the gold mines of the Witwatersrand and the mine electrician occupied a comparatively unimportant position, being responsible to the resident mechanical engineer at each property. As a consequence, the capabilities of some of the electricians were not of a high order, and the limitations in their responsibilities had resulted in their being, as a class, somewhat deficient in the power of handling men, the very quality to which many of the mechanical engineers owed their positions. Seeing that the change from steam to electricity was to come suddenly, it appeared likely that the gold mining industry would find itself short of men capable of taking engineering charge of the mine under the new conditions, unless some of the resident mechanical engineers were able to obtain sufficient electrical knowledge to enable them to retain their posts satisfactorily. It was to meet these conditions and to benefit these men that this series of lectures was compiled. The classes of electrical engineering work dealt with are, accordingly, to a great extent those which these men were most likely to need. As an ele-

mentary course in practical electricity this work is most valuable, embracing as it does a large field and covering those points of the most practical importance in the ordinary handling of electric power plants.

GENERAL METALLURGY. By H. O. Hofman. P. 909. Ill., index. McGraw-Hill Book Company, New York. For sale by the *Mining and Scientific Press*. Price \$6.

Metallurgical literature consists largely of treatises and monographs dealing with the metals proper and parts of metallurgical activity, with but few works that make any attempt to cover the entire subject in even a general way. It has been the aim of the present work to cover the field of general metallurgy in a manner which will be useful both as a text and reference work on the subject. While it is impossible to take up in detail, in a work of this size, all of the various branches of the science, Mr. Hofman has succeeded in presenting a volume which covers the subject in a most commendable manner. Special attention has been given to mechanical processes, as the tendency of modern practice is largely in this direction. The general literature of metallurgy has been drawn upon freely, and references will be found in the footnotes to most of the books and papers of importance which have been published on the subject. The thermo-chemical data have been taken from J. W. Richards' book on 'Metallurgical Calculations,' and many illustrations have been borrowed from R. H. Richards' standard treatise on 'Ore Dressing.' The work discusses in a general way the history of the metals, the physical and chemical properties of metals, alloys, and metallic compounds, the metallurgical processes, ores, fluxes, apparatus, and metallurgical products, and in detail fuels and refractory materials. The subject of fuel, being one of primary importance in most metallurgical operations, is covered in a most thorough manner. The many industrial fuels are discussed as to calorific power and applications. Briquetted fuel, which has come to be such an important factor in the European fuel market, and gives promise of a much more general use in the future, is discussed as to manufacture and use. As there is no material on the market that meets all of the requirements of a perfect refractory, the subject of the adaptability of certain refractory materials to certain uses is one which is an important metallurgical consideration and is discussed in an interesting and instructive manner. Electro-metallurgical processes are treated in a general manner, both as to processes involving the conversion of electrical energy into heat for the purpose of producing a temperature necessary for a process, and its use in the decomposition of a compound by wet electrolysis, where the amount of heat generated is relatively small or by dry electrolysis, where the amount of heat generated is necessarily large. The mechanical processes which are necessitated by metallurgical processes are also reviewed. Those operations involved in the crushing of ore, concentration, briquetting, rolling, forging, pressing, and drawing of metals and alloys for use in the arts; solutions have to be handled in wet processes and solids separated from liquids by filter-pressing or other mechanical means; smelting operations require forced draft or blast, and the air may have to be heated or cooled before it is made to act upon fuel or charge; the vapors and gaseous products of a process have to be withdrawn from the apparatus in which they are produced, and perhaps some of the metal recovered as flue-dust before the gases are allowed to pass off into the open. The mechanical appliances used in these processes are illustrated and their uses described.

In the present work the aim has been to cover the field of general metallurgy as a whole. The good of the older endeavor has been combined with that of modern research, and the whole has been treated from the point of view of the metallurgist who has a leaning toward physical chemistry.

A CIRCULAR SHAFT, 29 ft. in diameter and 221 ft. deep, with reinforced-concrete walls 5 ft. thick, has been sunk near Edmonton, province of Alberta, Canada, to serve a coal mine owned by French capitalists. It has taken 10 months to complete the shaft, and an output of 2000 tons of coal daily will be made when the equipment is finished.

Company Reports

HUTTI (NIZAM'S) GOLD MINES, LTD.

The Company was registered in 1901 to acquire, subject to the consent of the Nizam's Government, by assignment from the Hyderabad (Deccan) Co., Ltd., the mining rights over a leasehold area containing 92 square miles in the state of Hyderabad, southern India, held by the Hyderabad company from the Government of the Nizam, under their Raichore Doab Gold Fields lease, upon terms including a royalty of 5% in gold produced. The authorized capital is £70,000, in 70,000 shares of £1 each; 69,610 shares are issued and fully paid. The report presented in May 1913 covers the previous 15 months. During that time 27,733 tons of ore was crushed. The value of the gold recovered was £78,720, of which £63,055 was obtained from the mill and £15,666 from the cyanide plant. During 1912 the total working cost amounted to 34s. per ton of ore treated. The milling cost, inclusive of crushing and tramming, was 5.7s. per ton of ore crushed, and the cost of cyaniding was 2s. per ton. The ore reserves are approximately 20,000 tons, containing 15,000 oz. of gold. The full dividend for the 15 months was 10%. The credit balance on December 31, 1912, was £11,908. During the year £8000 was spent for a new Diesel engine, air-compressor, and other equipment. A slime plant is in course of construction, and a railway to the mine is to be started soon. The fuel and water supply is rather limited.

ABANGAREZ GOLD FIELDS OF COSTA RICA

The Company has issued \$3,880,000 of common stock and \$1,000,000 of preferred stock. Improvement work was started three years ago, it is hoped to be completed during this year, and it is anticipated the plant will then be able to handle at least 10,000 tons of ore per month. The results for 1912 were disappointing in that the ore-shoots which have hitherto yielded supplies of high-grade ore furnished a much poorer grade. For instance, one on the fifth level gave an average recovery of only \$9.65, as compared with an average of \$29.97 for the past seven years. The gross receipts from the sale of bullion were \$606,782.22. The rebuilt mill has forty 1250-lb. stamps on concrete mortar blocks, and ten more are being erected, while five tube-mills have been erected. Air-compressors, rock drills and stoping drills, and an electric hoist have been installed at the mine and a power-plant built on the Guacimal river; the total expenditure on improvements during the year amounted to \$222,781. To provide funds for this work, \$403,400 in three-year 6% notes has been issued, and \$106,500 in demand notes, the deficit of operating receipts as compared with expenditures for the year having been \$175,463. Charges for depreciation, amortization, etc., bring the total deficit to \$213,005.

SOUTH UTAH MINES & SMELTERS

The Company was organized under the laws of Maine, in 1909, and is a reconstruction of the Newhouse Mines & Smelters. The property comprises 13 copper-mining claims, two placer claims, and the townsite of Newhouse, in Beaver county, Utah. The authorized capital is \$4,300,000, in 860,000 shares of \$5 each; 654,800 shares are issued and fully paid. The report for 1912 gives the total shipments of concentrate and crude ore as 34,763 tons, with 5,921,864 lb. copper, 48,546.35 oz. silver, and 2,449,961 oz. gold. The net smelter returns were 5,527,810 lb. copper, 2,449,961 oz. gold, and 43,691.71 oz. silver. The average ratio of concentration was 12.51 into 1, and the average mill recovery was 59.09%. The total cost of mine operation was 83c. per ton, or 6.44c. per pound of copper; that of mill operation was 67c. per ton, or 5.19c. per pound of copper; that of smelting was \$2.22 per ton, or 17.17c. per pound of copper. The total net cost of operation was 15.50c. per pound of copper. The mine has little ore reserve developed. The No. 2 French orebody is the most promising find of the year; at present each foot of height proved in this orebody means a reserve of 1350 tons. The orebody averages, including a shoot of low grade in the centre, a little

better than 1% copper. The twelve months ended June 30, 1913, closed with a net loss of \$31,114.

IRON MOUNTAIN TUNNEL COMPANY

The holdings of this Company are at Superior, Montana. The authorized capital stock is 200,000 shares at \$10 each, of which \$1,700,000 is issued and outstanding. During the year, improvements have been made and new machinery purchased and installed. It was evident that the plant must be electrified throughout before it could be successfully operated. A contract was made with the Northwestern Development Co. providing for the delivery of electric power at 60,000 volts at the plant of the Iron Mountain Co. An ore-sorting plant was constructed, also an Ingersoll-Rand electrically driven air-compressor installed. A transformer house has been constructed, and a new boarding-house built. Plans are being made for the providing of \$35,000 additional capital so that a McQuisten tube concentrating plant, estimated to cost \$10,000, can be built. E. C. Smith, a minority stockholder, instituted suit to prevent sale of his stock for an unpaid assessment.

BROKEN HILL PROPRIETARY BLOCK 14 COMPANY

This Company was registered in Australia, in 1887, to acquire silver-lead mining property at Broken Hill, New South Wales, and a smelting works at Port Adelaide, South Australia. Additional leases near Broken Hill have since been acquired, and tungsten and bismuth properties in New South Wales. The authorized capital is £155,000 in 100,000 10% cumulative preference shares of 6s. each, and 100,000 ordinary shares of £1 5s. each, all shares being issued and fully paid. Concentrating works have been erected, but operations have been suspended since November 1907, and ore is now being sold. The present output is chiefly from the carbonate zone. The report for the half-year ended March 31, 1913, gives the tonnage of carbonate ore shipped as totaling 6992 tons, assaying 25.4% lead and 14.9 oz. silver, compared with 12,484 tons, assaying 28.63% lead and 15.99 oz. silver, during the previous period, the total metal contents being 1776 tons lead, 104,181 oz. silver, and 3574 tons lead, 199,619 oz. silver, respectively. The cost of mining was £1 15s. 6d. per ton, compared with £1 6s. 10.6d. in the previous term, the difference mainly caused by the scarcity of men suitable for this work and the consequent small output. The further continuance of carbonate ore work depends on the exploration of the old workings, and as extraction proceeds it becomes more difficult to maintain a steady output of ore of a suitable grade. For the half-year 9503 tons of sulphide ore was delivered at the Junction North, at a cost of 16s. 9.4d. per ton, the average value being 15.4% lead, 1205 oz. silver, and 12.01% zinc, these figures comparing favorably with previous shipments of 2173 tons assaying 15.1% lead, 11.9 oz. silver, and 11% zinc. The purchasers were unable to handle larger consignments, but as they have increased their capacity, it is hoped the next half-year will show an increased output. The working profit for the half-year was £6578 and the net profit £5805. One dividend was paid, of 1s. 6d. per share, amounting to £15,000, and the balance now standing at credit of profit and loss account is £72,569.

GREAT BOULDER PERSEVERANCE GOLD MINING CO.

The quarterly report of this Kalgoorlie company contains the following: Development covered 2157½ ft. The policy of developing the Furness and D lodes has been continued with good results, and the latter has been traced on the 900-ft. level. The finding of an eastern branch of the Lake View lode on the 2050-ft. level gives encouragement to resume work at the bottom of the mine. The average ore mined has risen from 6.39 dwt. for the previous quarter to 6.57 dwt. for the period under review. The grade of the ore treated during the quarter was below the average of the broken ore reserves; this has increased the average value of the ore remaining in the stopes. Broken ore in the stopes amounts to 172,107 tons averaging \$6.34 per ton. Ore treated, tons 61,691
Gold and silver production \$288,000
Working costs per ton \$4.37

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

A 100,000-CU. FT. FAN has been erected at the 'B' shaft of the Old Dominion, Arizona, for ventilating the west end of the mine, and the ventilation underground is already greatly improved.

AFTER a year's work with a continuous decantation and counter-current solution system of slime treatment, followed by dewatering on a Portland filter, Mr. Bowman, manager of the New Reliance mine, South Dakota, states that he is satisfied with the operation of the process. Recovery of gold is from 85 to 87%, and total milling costs are less than \$1.25 per ton. The plant is handling 100 tons per day. During July the total cost of mining and milling was \$2.48 per ton, which is good work.

MIXTURES of gas and air have three critical points, namely, when the mixture begins to be explosive, when it is most explosive, and when the mixture burns without explosion. Oil gas of the following composition begins to explode in proportions of 7 parts of gas and 93 parts of air: CO₂, 1.6%; C₂H₄, 6.8%; O₂, 0.2%; CO, 3.4%; H₂, 52.1%; CH₄, 30.8%; and N₂, 5.1%. It is most explosive when the proportions are 15.4 of gas to 84.6 of air, and the mixture begins to burn without explosion when the proportion is 24.5 of gas to 75.5 of air.

Cost of removing silt from harbors in British Columbia, by five different types of dredges, is as follows:

Type.	Hours dredging.	Material, moved, cu. yd.	Cost, cents per cu. yd.
Elevator	2,003	951,200	16.6
Suction scraper	2,386	2,597,500	5.8
Dipper	3,513	349,275	20.7
Dipper	3,444	576,125	26.2
Agitator-auction	2,786	1,006,570	12.5

ALUNITE is a mineral with a theoretical content of 11.4% potash (K₂O) and 37% alumina. While the mineral is seldom found pure in nature, its deposits are of importance as a possible source of both potash and alumina, and interest therefore attaches to several of the recent discoveries of this mineral by geologists of the United States Geological Survey. A recent investigation of the Nogales region, in southern Arizona, by F. C. Schrader, of the Survey, revealed a deposit of alunite. Analyses of rock samples collected from the Evening Star copper prospect by Mr. Schrader showed large percentages of alumina and potash, and while the discovery of the alunite was only incidental to the investigation of the copper deposits, it has served to suggest that other alunite deposits may be found in this formation, which occupies an area of many square miles. Another deposit of alunite discovered by Mr. Schrader is at Bovard, Nevada, where, he says, the rocks show as high as 10 and 11% of potash. The actual extent of the deposits of the Bovard district is not known, as the character of the rock was not recognized by Mr. Schrader on the ground, so that no prediction of the possible value is justified.

TWO SYSTEMS of rope transmission are in general use, the American or continuous rope, and the English or multiple-rope system. The former uses rope wound over the grooves of driving and driven sheaves with suitable idlers and tension carriages that automatically regulate the tension of wraps of rope over the various grooves. This is the system in general use today. The English, or multiple system, requires an independent rope with aplice for each groove on the driving sheave, and is nearly always used for heavy powers, large ropes being utilized on deep-grooved sheaves. No tension is used in this system, the rope running at moderate slackness, allowing the natural gravity or weight of the ropes to provide sufficient traction or tension. Rope transmission is adapted for use under many conditions im-

possible or impracticable with other methods of power transmission, especially for crowded conditions, long distances, and large powers. Its economy in cost and maintenance, its noiselessness, its smooth running and positive features, and its simplicity, compactness, and ease of distribution are recognized by engineers everywhere.

FERBERITE is the name given to an iron-manganese tungstate from the Sierra Almagrera, Spain, which contained 3% manganese oxide. The view that the name should be given to a practically pure iron tungstate seems to be somewhat prevalent, but the above example, and the common usage in regard to other minerals, do not justify this restriction. Analyses of ferberite from the Nederland-Beaver Creek area, Boulder county, Colorado, vary as follows: tungstic acid, 60.98 to 74.13%; iron oxide, 19.13 to 24.14%; manganese oxide, 0.08 to 0.69%; lime, 0.35 to 1.28%; silica, 0.71 to 16.10%; aluminum oxide, 0.46 to 3.10%; and magnesium oxide, nil to 0.59%. Ferberite is generally almost black, with a slight tendency to brownish black, and on fresh granular surfaces a weak steel-gray color. The lustre varies with the surface examined. The cleavage is perfect, and the mineral shows a tendency to break into thin crumbling plates. Small crystals are common in cavities. The specific gravity ranges from 7.1 to 7.5, nearly three times that of quartz. The streak made on a light colored, hard surface, or on rough porcelain, is dark-grayish black, suggestive of brown. The powder made by scratching the surface with a knife is black to very dark brownish black. The fusibility varies with the percentage of manganese present.

AMONG the more noteworthy alterations in Rand metallurgical practice that have taken place during the past two or three years, particular reference may be made to the tendency to equip ore-reduction plants with tube-mills of less capacity and length than hitherto. In the past most of the tube-mills, in fact all the mills installed on Witwatersrand mines, were 5½ by 22 ft. For some years these dimensions were regarded as the sizes of standard tube-mills. All mines under control of the Central Mining & Investment Corporation, for which fine-grinding practice was decided on, were of this size, according to the *South African Mining Journal*. The most recent equipment installed on the 'main reef' properties have, however, been 6 by 16½ ft. The new Van Ryn Deep 80-stamp mill includes eight 6 by 16½ ft. tube-mills, and the Consolidated Langlaagte 100-stamp mill contains ten mills of a similar dimension. Apparently the Johannesburg Consolidated Investment Co. has been the pioneer Rand firm in deciding upon a smaller size of tube-mill, but for some time past there has been a feeling among Transvaal metallurgists generally that shorter tube-mills than the standard 5½ by 22 ft. would do more economical work. It is understood that exhaustive experiments have recently been carried out at a leading Witwatersrand mine with a view to determining the most efficient and economical size of tube-mill. It is also stated that these researches have gone a good way toward proving that mills of even smaller dimensions than the 6 by 16½-ft. tube-mills erected at the Consolidated Langlaagte and the Van Ryn Deep will more nearly approach the ideal as regard the combined consideration of capacity, efficiency, and cost. It is expected that these tests will have an important and far-reaching effect on Rand ore-reduction methods. It seems probable, at any rate, that in the future such new mills as may be installed on the Witwatersrand will be shorter than the standard 5½ by 22-ft. mill. This view appears to be fairly widely held now, that in the larger size tube-mills five or six feet of the cylinder may be regarded as so much mechanical waste, having regard to the comparative horsepower cost of the large and small mills. Some time ago, the metallurgical department of the Central Mining & Investment Corporation installed an 8-ft. Hardinge mill for testing purposes at the Village Deep. These tests, it was understood, proved the mill to give efficient results on a fine product, but indicated that it did not give entire satisfaction with coarse particles of ore. It was stated that with screening of 100 mesh the mill did good work, and this mill was afterward purchased by that Company and now forms part of the permanent equipment.

Production Statistics

SALT AND BROMINE

The production of salt in the United States, including Hawaii and Porto Rico, in 1912 was 33,324,808 bbl. of 280 lb. each, or 4,665,473 short tons, valued at \$9,402,772. The corresponding figures for 1911 were 31,183,968 bbl., or 4,365,756 tons, valued at \$8,345,692. Thus for the year 1912 there was a gain of nearly 7% in quantity of salt produced and of nearly 13% in value as compared with the production of 1911. The average price of salt per barrel in 1912 was 28.215c., or \$2.02 per short ton, as compared with 26.763c. per barrel, or \$1.91 per short ton, in 1911. The following table gives the production and value of the salt produced in the United States in 1912, by states:

State.	Barrels.	Value.
New York	10,527,221	\$2,615,334
Michigan	10,946,739	2,974,429
Ohio	5,269,179	1,364,136
Kansas	2,573,626	844,292
California	1,090,000	620,196
West Virginia	139,121	66,023
Texas	373,064	290,328
Utah	283,293	154,734
Hawaii	8,286	9,180
Nevada	12,536	15,752
Other states	*2,101,770	445,868
Totals	33,324,808	\$9,402,772

*Includes Idaho, Louisiana, New Mexico, Oklahoma, Pennsylvania, Porto Rico, and Virginia.

Imports of salt totaled 998,664, and exports 445,785 bbl.

The production of bromine was 647,200 lb., valued at \$136,201. The industry is centred in Michigan, Ohio, Pennsylvania, and West Virginia. Calcium chloride is also produced from the industry, amounting to 18,550 tons, worth \$117,272, in 1912.

SAND AND GRAVEL

The total production of sand and gravel in the United States in 1912 reported to the U. S. Geological Survey by producers was 68,318,877 short tons, valued at \$23,081,555, as compared with 66,846,959 short tons, valued at \$21,158,583, in 1911, a net increase in quantity of 1,471,918 tons and in value of \$1,922,972 over the production of 1911. Sand for building purposes constitutes about one-third of the total production. In 1912 the production of building sand was 23,632,157 short tons, valued at \$7,904,321, as compared with 24,614,342 short tons, valued at \$7,719,286, in 1911, a decrease in production of 1,082,185 short tons, but an increase in value of \$185,035 over the production of 1911. The average value of building sand per ton increased from 31c. in 1911 to 33½c. in 1912. As there can be no appreciable diminution of the supply of building sand in this country in many years, the most plausible explanation of this increase in value must be higher wages paid to laborers. As 1912 was a year of prosperity and building was brisk, it seems hard to account for the falling off in production of building sand of more than 1,000,000 tons.

The tonnage of gravel produced exceeds that of sand. The total production of gravel used for concrete, paving, filter beds, roofing, road-making, railroad ballast, and other purposes in 1912 was 29,768,510 short tons, valued at \$7,737,942, in comparison with 26,592,982 short tons, valued at \$6,720,083, produced in 1911, an increase in quantity of 3,175,528 short tons, and in value of \$1,017,859. These figures show an increase in average cost per ton of gravel from approximately 25c. to 26c. Although in all probability wages paid to laborers have increased and tended to raise the cost of gravel, it is believed that the introduction of machinery during the year 1912 tended to reduce the average cost per ton, and hence the average value has changed but little.

The gravel figures for 1912 do not include, as they did in 1910, a considerable quantity of chats or tailing from the Missouri zinc mines and of chert used for road-building in Alabama and Tennessee. The production of chats in Missouri in 1912, as reported by the Missouri Bureau of Geology and Mines, was 2,723,403 tons.

Catalogues Received

BRAUN-KNECHT-HEIMANN Co., San Francisco, California. Catalogue No. 6. Price list of scientific apparatus. 592 pages. Illustrated, index. 6¼ by 9½ inches. This is an excellent publication and should have a place in the technical library of every mining company. It contains well illustrated and short descriptions of apparatus for analyses of ores, oils, asphalt, and cement; bacteriological apparatus; laboratory specialties and a long price list of necessary chemicals; and 100 pages dealing with laboratory machinery for which the name 'Braun' has become so well known. For prospectors there are given details of outfits at a low cost, while for assayers are given outfits for every occasion, besides the plan and description of a modern metallurgical laboratory. There is a complete list of prices of both common and rare minerals, useful reference tables, covering many subjects, and an excellent index, indispensable for this class of book. Analytical work at present is progressing so fast that consequently new and often complicated apparatus is necessary. Samplers, assayers, and chemists must be fully alive to this fact, and will find the latest in the volume under review. Perhaps some of the more interesting apparatus shown is the crushing machinery, oil-burning furnaces, balances, glassware, oil-testing methods, and the silica ware. The latter is superior to glass for many uses and is not as well known as it should be.

EDITORIAL

CIRCULARS and newspaper puffs are being liberally used locally to attract attention to a supposed new process exploited by the Foss International Ore Reduction Company. The statements made are so absurd as not to deceive any engineer for a moment; to all others we merely say, *don't*.

A GENERAL strike of the coal miners of Colorado was declared for September 23 by the unanimous vote of the Trinidad convention in which a resolution of the executive committee of the United Mine Workers of America indorsing the strike was adopted. The mining industry is passing through a period of severe industrial unrest, and it is to be hoped that with the settlement of these differences between the miners and operators a period of peace of more than a few months duration may follow.

GOLDFIELD suffered severely from a cloudburst September 23. While there was some loss of life and much of property, we are glad to report that both losses were less than at first thought. Electric service was interrupted, but aside from that the Goldfield Consolidated Mines Company escaped with little injury. The *Goldfield Daily Tribune*, with true journalistic spirit, overcame the difficulties of the situation, and by means of type and hand press, presented a readable if abbreviated Sunday issue the following morning. Having once suffered ourselves, we appreciate the effort this cost, and extend congratulations to our contemporary with our sympathy to the citizens of the desert city of gold.

REPORTS from the Lake Superior mines would indicate that there is being enacted a revival of Amazon warfare in that locality. The legendary women of the Black Sea and Caucasus are being impersonated by the wives of the striking miners, and the results obtained are equally as glorious as the victories over the ancient Greeks. In recent encounters at Planedale and Centennial between these modern Amazons, who have substituted the broom for the sword, and the strike-breakers, the attacking force would have triumphed had it not been for the arrival of reinforcements of women from the rival camp who turned the tide of battle. There may be some truth in the current phrase regarding 'The Female of the Species.'

SELECTIVE flotation offers large possibilities of usefulness, as is being found at a number of points. There is also much to be done through supplementary processes of preparing the ore for flotation as by Horwood's method of roasting. We printed Au-

gust 30 a general résumé of work now under way at Broken Hill in Australia. Our attention has been called to the fact that this was possibly misleading as to phrasing, since selective flotation is, admittedly, but a special application of the main process owned by Minerals Separation, Limited. In fact, the various methods being tested at Broken Hill are being operated under license from that Company, which owns the patents covering them.

MEXICO, on the sixteenth of September, celebrated the one hundred and third anniversary of her independence. The military display in Mexico City rivaled that of the centennial celebration of three years ago, and a great increase of patriotic sentiment is reported, as evidenced by the thousands of students who, having been organized into military companies, participated in the parade and are enthusiastic in their support of the federal government. Would it not be a still greater mark of patriotism for these students of the medical, law, engineering, and agricultural schools to exchange their gold braided regalia and cockades for the khaki and sombrero of the *rurale* and join hands with the government in the suppression of the revolutionary element which has all but deprived Mexico of her existence as a nation? The fighting qualities of an army which has been forced into service and largely recruited from the prisons and penitentiaries cannot be expected to be as great as that of an army inspired by patriotism and which is fighting for a cause. It is a consolation to the Americans on this side who have friends and relatives in Mexico to know that the *grito* of '*Viva la Independencia*' has not been changed to '*Mueren los gringos*,' as is annually rumored and predicted in Mexico at this season of the year.

Genesis of Butte Ores

Among notable features of the Butte meeting of the American Institute of Mining Engineers, common opinion ranks high the presentation of the paper by Mr. Reno Sales on the origin of the Butte ores. It is too voluminous, and too full of significant observation and keen inferences, to permit of adequate review here. Based as it is on fifteen years work of a well trained corps of geologists following a plan proposed by Mr. D. W. Brunton, developed by Mr. H. V. Winchell, and for the last dozen years executed by Mr. Sales and his excellent staff, it forms probably the most thorough and most accurate geologic study ever made of a similar area; one, moreover, which has been explored to a depth not greatly disproportionate to its horizontal extent. An excellent feature of the work has been the unflinching discrimination of fact and inference and the painstaking recording day by day of the exact position of the various rocks, veins, and ores in miles of underground workings. No geologist or engineer can study Mr. Sales' maps and sections, unfortunately too large for reproduction here, without recognizing the immense amount of work that has gone into their making, and without realizing that they constitute a mine of information and a standard for the future. If other great companies

will follow the lead of the Anaconda Copper Mining Company in establishing, and especially in patiently maintaining, similar geological departments, we shall have in time a solid basis for deductions regarding ore deposits. That the work will justify itself as an economic measure, may be judged by the results at Butte, where single blocks of ore found as a result of this close study have more than paid for the whole work.

While to mining engineers the greatest value of Mr. Sales' work lies in the structural studies, the geologist will have keenest interest in the light thrown on genesis of ores. Mr. Sales believes that the Butte ores are the result of "one period of mineralization, varying in intensity, possibly, from time to time, with important changes in chemical character of solutions." He explains most ingeniously the differences between the copper veins of the central area and the silver-zinc veins of the peripheral region, as the result of the change of solution from acid to alkaline character as the originally acid waters penetrated the dominantly alkaline rocks. This appeals to us as sound, though a question arises as to what caused deposition from acid waters of the copper, if acidity was a condition of their being carried in solution. Other questions may be raised, and more light is needed, but at least the facts of occurrence are on record.

One of the controversial questions at Butte is as to the origin of the chalcocite. Following the first work on secondary enrichment, it became popular to look on all of it as secondary. Deeper exploration seemed to necessitate a change in this view, and Mr. Sales holds that much of the chalcocite ore is of primary origin. We present his argument on another page. It will be noted that in the main, he rests his case on structural evidence, and this we believe to be sound. Recognizing fully the debt that geology owes to the chemists, and the need, as urged by Mr. J. W. Richards at Butte, for further synthetic studies, we own a preference for the results of structural sections and maps. If an orebody is in a certain place, the argument that it is chemically impossible for it to be there carries little weight. We make haste to say that any such contretemps is probably to be charged to the geologist who has been unable to give to his confrere an accurate account of the conditions to be met. Much credit is due to the long list of chemists who are patiently trying to help the geologist with his problems, but in the main their work must be to explain already discovered facts, rather than to furnish any wealth of criteria for future use. An excellent case in point has just arisen in the matter of the origin of pyrite. Studies made at the Geophysical Laboratory at Washington, which we discussed in our issue of September 30, 1911, pointed clearly, almost conclusively, to the rule that with cold waters and under surface conditions marcasite and not pyrite would be formed, that the latter was generated through the action of hot alkaline waters. This rule, if correct, would afford a convenient and widely useful basis for discrimination. Unfortunately, studies in the laboratory of the University of California, since completed, have resulted in formation of excellent

crystals of pyrite under surface conditions with acid waters, and so the criterion loses its value. The conclusion of the whole matter seems to be that each should faithfully record the facts as he sees them day by day; the interpretation will change as knowledge increases, but the facts are inviolate.

Trailing the Nitrogen Atom

The chemist, in surveying the universe, has much reason to feel that, if he had the power, he could remold it nearer to our present needs. It has often been pointed out that the relative abundance of the chemical elements and the ease with which they can be obtained and utilized bears no proportionate relation to the needs of man. Manganese is as easily produced as iron and is much more abundant than copper or lead, but is of exceedingly limited usefulness. Titanium is more abundant than carbon, but is of almost no use. Potassium is one of the most abundant and useful elements, but is widely distributed in small amounts only, and its recovery either in the form of salts or in the metallic state offers so much technical difficulty as to constitute one of the leading chemical problems of the day. But the most conspicuous case of maladjustment is nitrogen, which is everywhere present, forming nearly 80 per cent of our atmosphere, and yet is one of the most difficult elements to obtain in any form which is useful to animal and vegetable life. Animals, which must have nitrogen to form their proteid matter, are indeed totally dependent upon vegetable life for their supply, having no other means of obtaining it than by eating vegetables or other animals. Plants, though growing in an atmosphere largely composed of nitrogen, draw with difficulty their supply from the soil, where the obscure processes of nitrogen-fixing bacteria, the natural process of the decay of organic material or of rocks, and the slight effect of electric discharges in the air, together supply enough to maintain a limited stock of the necessary element. This suffices for the metabolic processes of living matter, but in the field of chemical industry more concentrated sources of supply are necessary, since great quantities of nitrate are consumed in the manufacture of explosives, fertilizer for stimulating the growth of plants, and a host of recent products, such as collodion, celluloid, and artificial silk, to name but a few.

Unfortunately, the nitrates of all the common elements are soluble salts, and hence the ordinary processes of nature whereby deposits of substances are formed have not run their usual course. Nowhere in the world, except in Chile, have deposits of nitrates of notable size been formed. Every rule has its exception, however, and in northern Chile, in what is probably the driest climate in the world, opportunity has been afforded for the formation of deposits of sodium nitrate of large size and occurring over a large area. Upon this district the world is dependent for nearly its whole supply of nitrate salts, and the output has grown in the past century from nothing to over 6,000,000,000 pounds per year. At the present rate of production the known supply will only suffice for less than a half century more.

Foreseeing the pressure of urgent necessity, chemi-

cal engineers have already begun to develop methods of tracking down and seizing the elusive nitrogen atom. It has long been known that electric discharges of high potential cause the nitrogen of the air to combine with oxygen, thus putting the nitrogen in usable form. A dozen years ago two Americans, Messrs. C. S. Bradley and R. Lovejoy, patented a method of thus producing nitric acid from the nitrogen of the air. This was a technical success but a commercial failure; the cost of the electric energy required being prohibitively high. At about the same time Messrs. Christian Birkeland and Samuel Eyde built a similar plant at Ankerlokken, near Christiana, Norway. The lower cost of power there made operation feasible and a later plant built at Notodden is now using 60,000 electrical horse-power in the manufacture of nitric acid. According to Mr. Thomas H. Norton, United States consul at Chemnitz, Germany, who has recently made a comprehensive report on the nitrate industry, the cost of electric power at Notodden is \$2.94 per horse-power year, and at Odde, on the west coast of Norway, it is being produced for \$1.96 per horse-power year. This places electrochemical industries on quite a different basis from that prevailing in the United States, where a lower production cost for electrical energy than \$10 per horse-power year is uncommon.

A more promising method of fixation of atmospheric nitrogen is the manufacture of CaCN_2 , nitrolime, or cyanamide, as the commercial product, an intimate mixture of this substance with lime, carbon, and calcium carbide, is generally called. This is produced by passing nitrogen over hot calcium carbide, and contains on the average 20 per cent nitrogen. By treating this with super-heated steam, ammonia can be formed for industrial uses, or the nitrolime can be directly utilized as a fertilizer. The chief American producer, the American Cyanamide Company, which has a plant of 12,000 tons yearly capacity at Niagara Falls, Ontario, is now enlarging its plant to a capacity of 50,000 tons per year, and is selling its product in such distant places as Porto Rico, Hawaii, and the Philippines. The Company is obliged to secure its electric power from the Ontario Power Company, at rates which are probably not unusually low.

A further possibility is the development of the natural processes of nitrate formation. In the decay of organic matter nitrates are naturally formed and under proper conditions can be leached out and utilized. It was thus that the necessary supplies of potassium nitrate for the manufacture of powder were obtained in this country during the progress of the Revolutionary war. The present high cost of labor, the slow reactions, and the scanty yield of this method have caused it to be neglected, but with the ever-increasing knowledge of bacterial action it is not impossible that improved methods may in time be devised for the conversion of the atmosphere from a useless deluent into a valuable chemical substance. It should be added that an important source of the present supply of ammonia is as a by-product of the distillation of coal, but the demand for ammonia is so great that additional sources of supply are still necessary.

Solution Control in Cyanidation

By A. W. ALLEN

The generally accepted equations of zinc-box reactions indicate the formation of a double cyanide of zinc and an alkaline earth as a by-product resulting from the deposition of the gold and silver. This reaction undoubtedly occurs in alkaline as well as neutral solutions. Silver nitrate titrations of such solutions may indicate either the content of free cyanide or of total cyanide. In the former case the result shows, roughly, the amount of potassium, sodium, or calcium cyanide present, which is generally recorded in terms of the potassium salt. On the other hand, a total cyanide estimation serves to indicate the content of free cyanide plus the equivalent, also in terms of potassium cyanide, of the double cyanide present; and also the hydrocyanic acid.

Estimation of Free Cyanide

Since the commencement of the industry it has been generally taken for granted that free cyanide content may be estimated by the direct addition of standard silver nitrate to the working solution; and total cyanide by the same method, after the addition of alkali. Since cyanide treatment invariably includes the precipitation of gold and silver by zinc, and since the great majority of cyanide operations are conducted with alkaline solutions, it is exceedingly difficult to understand how any line of demarcation can be drawn. By the adoption of such a method it will be seen that if the alkali is added in the plant the subsequent titration of the solution would reveal a high free cyanide content; if added in the laboratory, a high total cyanide content. The adoption of such a line of reasoning must necessarily mean the general acceptance of the theory that the addition of alkali to a working solution containing the double cyanide of zinc and an alkaline earth results in the entire regeneration of the cyanogen in the double salt, and its conversion into potassium, sodium, or calcium cyanide. This, again, is tantamount to saying that in a normally alkaline solution, gold and silver are precipitated in the zinc-boxes, and free cyanide regenerated. My own experiences of the behavior of plant solutions in connection with the solution and precipitation of gold and silver are entirely opposed to this idea. As far as I know, there is no evidence to show that any such regeneration occurs in actual practice, or that the double cyanide in question may be formed by the addition of acid to a normal plant solution carrying zinc salts, which is an obvious corollary.

Titration Results

In protectively neutral solutions the titration with silver nitrate gives free cyanide content. In protectively alkaline solutions the titration gives free cyanide content, plus the equivalent in terms of potassium cyanide of the double salt, in proportion to the amount of protective alkali present. In the presence of sufficient alkali the estimation becomes a total cyanide one, although often reported as free

cyanide. I therefore suggest that the result of a simple titration of a working solution with silver nitrate is of no definite value or significance, since only in the absence of free protective alkali would the result represent actual free cyanide content. In the presence of free protective alkali the result might indicate anything from available free cyanide to unavailable or only partly available double cyanide.

In a neutral or acid solution the titration would exclude the hydrocyanic acid. By a comparison of actual solution tests I have evidence that this substance is equally powerful with free cyanide as a solvent for gold; and, as a result of the definite recognition of its solvent powers in the Gitsam process, it may be suggested that the occasional success attending the practice of heating cyanide solutions is, in some measure at least, due to its liberation, added to the fact that, under conditions of low alkalinity, its content is not included as an available solvent in the result of the simple titration test.

It seems, therefore, unreasonable that the efficiency of a solution should be arrived at by a method which, under certain conditions of alkalinity, would exclude a powerful solvent; and, under other conditions of alkalinity, would include in the result the cyanogen in a zinc salt which makes the solution unworkable when the content rises above a certain percentage.

Precipitation on Zinc

An inevitable result of precipitation with zinc is the inclusion of zinc salts in the working solution. With an excess of free cyanide and a moderate alkalinity in the solution entering the zinc-boxes, the ordinary titration method will give a higher free cyanide content at the tail than at the head of the box. In other words, the solution will appear to have a higher efficiency after the addition of zinc than before it. This fact may be cited as a striking instance of the absurdity of this method of testing, since it is obvious that ultimate fouling of solution may be entirely due to the addition of zinc as a concomitant of precipitation.

The following figures of actual titration results of solution entering and leaving the zinc-boxes are of interest:

	Incoming, per cent.	Outgoing, per cent.
Total cyanide	0.175	0.175
Free cyanide:		
Direct titration method.....	0.145	0.150
After neutralization of solution on basis of protective alkalinity ar- rived at by Green's method.....	0.120	0.095

It is my opinion that the lack of a uniform method of determining the available and partly available cyanogen contents of a working solution is, in the main, responsible for many of the opinions expressed from time to time as to the effect of alkalinity on extraction. For example, a definite 'cyanide strength,' based on the simple titration with silver

nitrate, is being maintained, for some reason the alkalinity rises and, in proportion to the amount of rise, the zinc double salt appears in the result of the titration. The 'cyanide strength' is then brought down to normal by a decrease in the amount of fresh cyanide added. The solution or precipitation of gold becomes unsatisfactory and the high alkalinity is suspected as the cause. This is then lowered. The 'cyanide strength' drops in proportion and is raised to normal by the addition of fresh cyanide. The extraction or solution troubles disappear and the previous poor results are attributed to the alkalinity. In all probability the method of titration of the solution was at fault and indicated a 'cyanide strength' when sufficient alkali was present which bore an entirely different ratio to the actual available cyanide than did a corresponding titration when the solution was neutral or of a low protective alkalinity.

Chemical Reactions

The following equations probably represent the reactions occurring during the titration of a solution containing free cyanide and zinc potassium cyanide.

(1) Free cyanide

(2) Zinc-potassium cyanide

In each case the end point is indicated by the precipitate of silver cyanide formed by the excess silver nitrate on the potassium silver cyanide.

If sufficient acid be carefully added to an alkaline plant solution so that neutrality, as far as protective alkalinity is concerned, is obtained, then none of the cyanogen existing in the form of simple cyanides of the alkaline earths, or the double cyanide of zinc and an alkaline earth, will be affected; and a titration can then be made with neutral potassium iodide as indicator, which will give an estimate of free cyanide present. On the other hand, the raising of the alkalinity by the addition of excess caustic alkali will not affect the behavior of the standard solution toward the free cyanide present; but the cyanogen existing in the form of the double cyanide of zinc and an alkaline earth will, together with the hydrocyanic acid, and in presence of the excess alkali, postpone the end point until all the cyanogen existing in the form of free cyanide, hydrocyanic acid, and double cyanide, has been recorded.

The following results of the careful addition of weak acid to a plant solution carrying free cyanide and double cyanide are of interest; and serve to demonstrate that there is no loss of cyanogen.

Series 1.			
	Prot. alk., %	KCy, %	
1	Neut.	0.125	(free)
2	0.005 (NaOH)	0.137	
3	0.007 "	0.138	
4	0.010 "	0.140	
5	0.012 "	0.140	(total)

Original solution tested with alk. KI and AgNO_3 . Re-

sult, 0.14% (KC_y). Protective alk. then neutralized with N/10 HNO_3 ; then gradually raised with NaOH. Solution tested with AgNO_3 and neut. KI at definite intervals of alkalinity.

Series 2.			
	Prot. alk., %	KCy, %	
1	Neut.	0.160	(free)
2	0.003 (NaOH)	0.162	
3	0.006 "	0.165	
4	0.008 "	0.170	
5	0.011 "	0.175	(total)

Original solution tested with alk. KI and AgNO_3 . Result, 0.175% (KC_y). Solution then treated as in Series 1.

The necessity for adequate solution control work was exemplified in a recent experience. Routine titration for 'cyanide strength' had been made regularly and showed no material alteration in the composition of the solutions. Precipitation went from bad to worse in spite of the adoption of all the usual methods of regaining control. The solution was then analyzed and was found to contain a high zinc content and also a considerable amount of copper. Acid treatment was tried for the purpose of removing the double salts, but was abandoned because no satisfactory method of application could be evolved. The use of potassium permanganate was also tried and abandoned on account of the precipitation of the gold in considerable quantities (as with the acid method) together with the zinc and copper. The difficulty of collecting the precipitate from either reaction, or of doing anything with it when collected, prohibited the practical utilization of either method. Electrical precipitation, on an experimental scale, was also tried and the idea abandoned.

Solution Control

The question ultimately resolved itself into one of solution control. As the source of copper was temporarily at an end the free cyanide strength of the solution was dropped to a minimum and the bulk of the copper allowed to deposit on zinc shavings, the latter being removed and replaced by fresh zinc as soon as thoroughly coated. This took about two days, during which time there was practically no precipitation of gold. As soon as all the copper had been removed in this manner the free cyanide content in the solution entering the zinc-boxes was raised considerably, the idea being that a point of saturation had been reached with the normal strength and that further solution of the zinc was impracticable without an increase in the normal free cyanide content. This solution of the zinc was considered necessary for the formation of the hydrogen which, in a nascent form, was an essential element in the breaking up of the potassium gold cyanide in the solution entering the zinc-boxes.

The outgoing solution showed an immediate drop in valuable content, and as soon as satisfactory precipitation had been secured the discharging of barren solution with the residue was commenced and the usual water wash abandoned. By these means the excessive amount of zinc was removed from the solution, the coppery zinc was gradually replaced in the boxes, and the free cyanide content was allowed to drop to normal without any interference with the efficiency of precipitation. In subsequent operations

*Clennell, 'Chemistry of Cyanide Solutions,' p. 37.

a mixed solution and water wash was used, and sufficient barren solution (amounting to about 15% of the tonnage treated) was discharged with the residue to prevent the accumulation, above a workable limit, of undesirable compounds.

Zinc Losses

It is interesting to note in passing that the quantity of zinc so discharged in the residue is but a small fraction of the amount which disappears daily from the plant. The loss of zinc from plant solutions is a mystery which has yet to be definitely solved. Virgoe suggested the formation of an insoluble double carbonate as a result of a possible combination of zinc potassium cyanide with atmospheric carbon dioxide. Whatever the cause, it is evident that the automatic reduction of zinc content prevents the fouling of cyanide solutions in the great majority of cases. Under other conditions, however, as in the present instance, the reaction stops at a certain point, after which active measures must be taken for the removal of an undesirable accumulation of zinc. The strength of the cyanide solution entering the zinc-boxes must often be increased in proportion to the amount of zinc in such solution; and an unnecessary consumption of both solvent and precipitant results from an endeavor to effect satisfactory precipitation from foul solution.

As soon as facilities were secured it was deemed advisable to go more into detail in the matter of solution control, especially with regard to the estimation of zinc content. Independent tests were then made for total cyanide, free cyanide, and protective alkali. An additional test for hydrocyanic acid was also included and a modification of Bettles' was decided upon. The result of this test gives free cyanide plus hydrocyanic acid, which is practically an available cyanide result in the absence of protective alkali.

A résumé of the complete series of tests is as follows:

Estimation.	Principal salts indicated in result.	Preparation of solution.	Indicator	Titrated with	End point.
Total cyanide	KCy, NaCy, CaCy ₂ , K ₂ ZnCy ₄ , HCY	Add excess caustic alkali	KI	AgNO ₃	Yellow opalescence
Protective alkali		Add K ₄ FeCy ₆ ; then slight excess AgNO ₃ over that required in previous test	Phenolphthalein	N/10 HNO ₃	Disappearance of red coloration
Free cyanide; i.e., available cyanide in presence of protective alkali	KCy, NaCy, CaCy ₂	Add N/10 acid till protective alkali is neutralized; i.e., amount shown necessary in previous test.	Neutral KI	AgNO ₃	Yellow opalescence
Available cyanide, in absence of protective alkali	KCy, NaCy, CaCy ₂ , HCY	Add NaHCO ₃	Neutral KI	AgNO ₃	Yellow opalescence

The effect of dilution in the titration for total cyanide of a solution carrying the double cyanide has been discussed by other investigators. As a means of emphasizing the necessity for strict uniformity of operation, the following is instructive.

TOTAL CYANIDE ESTIMATION RESULT

Plant solution:	(KCy), %.
Undiluted	0.167
Diluted with equal bulk of water.....	0.172
Diluted with twice bulk of water.....	0.157
Diluted with three times bulk of water.....	0.175

Experiments made by me showed that reverse titrations for total and free cyanide gave almost identical results as direct ones, indicating that the amount of silver nitrate added by the ordinary method in quantity sufficient to give a distinct end-point, although in actual excess of the amount required to satisfy the equation, gives for all practical purposes a substantially correct estimate.

Protective Alkali

Green's method, as outlined, seems to be the most satisfactory, provided strict uniformity is observed in the amount of excess silver nitrate added.

It has been found preferable in estimating protective alkali under conditions of low alkalinity to count the number of drops of dilute acid necessary to neutralize a small amount of cyanide solution, rather than to attempt to read the burette. In the subsequent estimation for free cyanide the slow addition of acid is essential; and this is best made by adding the exact number of drops shown to have been necessary by the preceding test.

The free cyanide method is one of many given by Clennell,² and in my opinion, gives uniformly satisfactory results.

Hydrocyanic Acid

The bicarbonate should be added only in moderate excess, and a check test occasionally made to correct for the presence of carbonate. The inferred definition of 'available cyanide' in connection with the result of this test is consistent with my experience of actual practice.

In all of the above tests for cyanide the formation of a cloudiness inevitably preceded the appearance of distinct opalescence. The latter indication has

been looked upon as the only reliable end-point. In the present instance control testing is not considered in the light of an analysis of the solution, but rather calls for a quick and sufficiently reliable method of arriving at results of comparative accuracy.

¹Proc. Chem. Met. & Min. Soc. of S. A., Vol. I. p. 165.

²Chemistry of Cyanide Solutions,' pp. 25 and 26.

The difference between the free cyanide result in the presence of protective alkali or the available cyanide result in its absence, and the total cyanide result, gives an approximation of the amount of the double salt present, in terms of potassium cyanide. One fourth of this amount gives an estimate for zinc in the form of the double cyanide.

Use of Burettes

Standard solutions, indicators, and correctives, are all measured from burettes. These are mounted on revolvable stands with the result that the complete series of tests can be made very rapidly; and absolute uniformity of condition is assured for each estimation.

The final estimation for zinc content as double cyanide has been checked by analysis for total zinc in the same solution made by the sodium sulphide, ferric sulphate, and potassium permanganate method.

	Methyl orange.	Phenolphthalein.
K_2ZnCy_4	4KOH
4KOH	4KOH	4KOH
$Zn(OK)_2$	2KOH	2KOH
4KCy	4KOH	4KOH

The addition of alkali to a protectively neutral solution carrying the double cyanide should, therefore result in an increase in the sum total alkalinity to phenolphthalein, and a decrease in the sum total alkalinity to methyl orange. A number of tests that I have made would seem to indicate that the supposed reaction does not occur. The end points with the phenolphthalein are slightly uncertain, but in no instance was it possible to show an increase of alkalinity to this indicator. It was equally impossible to show a decrease in the alkalinity due to the methyl orange.

The figures in the following test will serve to indicate the method employed:

Volume.	Cyanide (as KCy)		Alkalinity (as KOH)		
	Total, %.	Free, %.	To Phenolphthalein.	To Methyl Orange.	
50% working solution	0.114	0.057	0.015	0.115
50% added alkali	0.052	0.052	0.054
Numerical average	0.057	0.028	0.026	0.033	0.084
Titration average	0.057	0.028	0.026	0.031	0.084

The direct titration results were slightly higher than those from analysis, the greatest difference amounting to 0.005%. These differences were consistent and comparisons were made from solutions carrying variable amounts of zinc. The results indicated the comparative accuracy at least of the direct titration method on the solution in question.

Acidity and Regeneration

At one time I made some experiments to determine whether it might be possible, under ordinary conditions, for the double zinc salt in a plant solution to be locally decomposed in contact with an acid ore or an acid water, according to the equation:

The conclusions arrived at were that such decomposition was possible in a solution of low free cyanide content; but that the hydrocyanic acid formed is so entangled with the precipitate of zinc cyanide that subsequent contact with alkali would result in a reversion to the original compound thus:

rather than conversion of the hydrocyanic acid into a cyanide of the alkali.

Alkalinity and Regeneration

The equation upon which the suggestion of regeneration of free cyanide by means of alkali is as follows:

This equation must be assumed in all cases where the simple titration of an alkaline working solution is expected to indicate free cyanide content.

According to Clennell³ the alkaline equivalents should be as follows:

In the above test the amount of alkali added was calculated so that the recognized direct titration method of testing, as advocated in the most recent text-books on metallurgical practice, would indicate the whole of the cyanogen content of the solution as free cyanide.

Mechanical Mixture

In considering the figures it is interesting to note that as regards total alkalinities, the figures favor the assumption that nothing more than a mechanical mixture has taken place. It is also noticeable that the actual titration average of the protective alkali is in agreement with the numerical average. Had regeneration occurred there would have been a reduction in protective alkali content, free alkali being used up to complete the reaction and the alkaline free cyanide so formed being reduced to neutrality as a result of the addition of silver nitrate, after the ferrocyanide, in the protective alkalinity test.

Another point worthy of notice is that the neutral solution, free or available cyanide result, minus the alkaline solution, total cyanide result, gives a definite idea of zinc content. The direct titration method is of no value in this connection and, as a result, the fact is often overlooked that a solution may be as foul with zinc after the addition of alkali as before it. This quantity of zinc in solution is an important factor in the efficiency and economy of operations. Its presence invariably affects the precipitation and sometimes the solution of gold, and a regular estimation of its content is second only in importance to an estimation for free or available cyanide. The cumulative ill effects of adding cyanide in lumps at the head of the zinc-boxes in an effort to improve precipitation is indicated by the subsequent determination for zinc content. The system is an unsatisfactory palliative rather than an actual remedy, pre-

³'Chemistry of Cyanide Solutions,' p. 60.

epititation only being effected by an increased addition of zinc and a further fouling of the solution.

Satisfactory precipitation, from an economic point of view, is more a question of ultimate value than actual metal content. The 'barren' solution after gold precipitation may contain a few grains per ton as compared with a corresponding 'barren' solution after silver precipitation which may contain as many pennyweights. Each may be referred to as the residue after satisfactory precipitation, but it is obvious that the question of zinc content is more important in the case of the treatment of gold ores where a complete or nearly complete precipitation is essential, a small percentage of the metal representing a high money value. In either case the precipitation is at maximum efficiency at the commencement of operations and deteriorates with the accumulation of zinc in the solution.

In conclusion, it may be added that, in piecing together the above notes, a deal of recognized information on zinc precipitation has been included for the sake of clarity. I wish to acknowledge the fact and would make especial reference to J. E. Clennell, whose handbook on cyanide solutions is of especial interest and value.

Minerals in Persia

Writing in the *Near East*, M. Charles Brouard, a mining engineer, who has spent many years prospecting and traveling in Persia, gives interesting details regarding the mineral wealth of that country. In M. Brouard's opinion, Persia will be one of the great oil-producing countries of the future. Apart from this, it will produce large quantities of gold, silver, copper, lead, and iron. The province of Azerbaijan, with the goldfields of the Kalu river, is generally considered as the richest in mineral wealth, but geological considerations seem to point to Luristan as equally worthy of the attention of European capital. The same remarks apply to Turkish territory situate immediately beyond the western frontier of Persia. Copper ore is frequently found. The most frequent forms are chalcopyrite, malachite, azurite, and chalcosite. M. Brouard discovered an extensive manganese orebody in the vicinity of Kerman, and says that on the whole the manganese group is represented by better ore than that found in the Caucasus. The pyrolusite contains lime, practically no phosphorus, and yields an average of 40% manganese. With regard to bitumen, an interesting discovery which M. Brouard made along the Top é Khazab, in the Kuh Jahak, was a four-mile deposit of bitumen. "The rocks here were dripping bitumen from all their cracks. The bitumen itself lay as a soft bed two to five feet deep at the bottom of the river. As a rough analysis showed, its purity is nearly equal to that of Utah. Its nearly complete solubility in carbon bisulphide and the distillation products denoted the presence of a large quantity of fluid hydrocarbons, not many gaseous products, and only a negligible quantity of sulphur; its specific gravity was 1.25." The country gives promise of future development.

Progress at the Buckhorn Mine

This property is situated in Eureka county, Nevada, and is controlled largely by those interested in the Goldfield Consolidated Mines Co. At the Buckhorn mine both north and south branches of the haulage adit are being driven, and raises from this adit to the levels above have been started.

The Buckhorn mine produces an ore of a taley nature containing about 40% silica. The scheme of treatment in the 300-ton mill under construction is as follows: Ore is dumped into a steel storage tank of 550-ton capacity, from which it passes over a shaking-screen with 1-in. apertures, the oversize being crushed by a 10 by 20-in. Blake crusher. The crushed product and screen undersize go to a revolving trommel 12 by 36 in., oversize going to

BUCKHORN MILL.

15 by 40-in. rolls, choke fed. Undersize from the trommel, with the roll product, is fed to a 6-ft. Hardinge conical ball-mill with spiral feed. Two bucket elevators, one being a stand-by, with 19-ft. centres and a 12-in. belt, lift the pulp to two 45-in. Akins classifiers. These work in closed circuit with two 5 by 18-in. tube-mills. The final overflow from the classifiers goes direct to the Dorr agitators. These are filled by a distributor, agitation being through the centre column and distributor, the arms raking pulp to the centre. Agitation is done in three vats in series. From these the slime goes to three Dorr thickeners from which the thickened pulp is run to a second battery of three, here meeting with solution from revolving filters and other barren solution. The overflow from the second three flows into the first three, and overflow from the first three is precipitated by zinc dust. Slime is treated on four Oliver filters, and the residue is agitated by four vortex mixers and discharged. The mill buildings will soon be covered, and machinery is now being installed. About 25 men are engaged on construction of the power-plant at Beowawe, and the 30-mile transmission line to Buckhorn is practically completed. S. J. Kidder is general manager of the property.

The Wettlaufer Lorrain mine at Cobalt shipped the following ore during 1912:

Class.	Pounds.	Silver, oz.
First	349,954	561,050
Second	219,939	56,785
Concentrate	385,451	191,184
Bullion	673	6,979
Total	956,017	\$15,998

Origin of the Butte Chalcocite

By RENO SALES

*Owing to the persistence to great depths of the mineral chalcocite in the Butte copper veins much interest has been aroused among geologists concerning the manner in which it was formed. In recent years the opinion has been quite generally held that chalcocite is largely, if not wholly, a product of descending sulphide enrichment. This view arose naturally through the discovery of the so-called 'black sulphurets' (later proved to be sooty chalcocite) of Ducktown, Bisbee, and similar pyritic ore-bodies. These belts of black amorphous chalcocite were found separating the oxidized zone from the lean pyritic ore below and they were early believed to have resulted from the reaction between the descending copper sulphate waters and the unchanged primary ores below. That this view was the correct one for the sooty chalcocite of this class of deposits has been abundantly proved by recent investigations.

Early Discoveries

The discovery of similar chalcocite ores in the early mining operations at Butte led many observers to the opinion that these remarkably rich ores were likewise of secondary origin and of limited vertical extent. When the zone of sooty chalcocite was penetrated, however, the predicted lean cupriferous pyrite ore was not encountered, but chalcocite-bornite-enargite ores were found, which have persisted to great depths. The chalcocite of the deeper levels does not occur in the sooty form, but instead, it is the gray massive mineral more or less intimately mixed or intergrown with bornite, enargite, or other ore minerals replacing directly altered granite. It is not necessarily a replacement of pyrite or any other sulphide mineral, being deposited directly from solution as chalcocite in veins along with bornite and other copper sulphides.

The problem of the formation of the chalcocite in the Butte veins was studied recently by C. T. Kirk,¹ who endeavored to work out a definite relation between the chalcocite deposition and certain stages of granite alteration. He concludes that such a relation exists, and that the chalcocite formation is, in the main, associated with a certain phase of granite alteration which has developed through the action of descending meteoric waters. W. H. Weed,² in his recent report on Butte, likewise declares that most of the chalcocite has resulted from descending waters, although primary chalcocite also occurs, but just how and where he fails to state. Many other writers familiar with these ore deposits, notably H. V. Winchell and the late S. F. Emmons, regarded the chalcocite as chiefly of secondary origin, at the

same time holding the view that some of it might be primary. Recently, however, Mr. Winchell³ has expressed the view that the deep chalcocite is largely primary.

Deposition of Chalcocite

An intimate acquaintance with these ore deposits extending over a period of years has led me to the conclusion that most of the massive chalcocite is of primary origin, in the sense that it was deposited in its present position directly from deep-seated ascending solutions. Secondary chalcocite exists in large quantities also, but it is believed to be of limited vertical extent, being confined principally to the well known sooty chalcocite zone extending from the bottom of the oxidized zone to depths ranging from 100 to 1200 ft. It should be clearly understood, as previously stated, that the sooty glance zone has no well marked lower limit, and furthermore, in the generation of sooty glance by descending waters, massive chalcocite is frequently developed, especially where the replacement of pyrite or other sulphide has reached an advanced stage. It is impossible to differentiate in hand specimens between primary and secondary chalcocite when both appear in massive form. There is of necessity in many cases an overlapping of primary and secondary chalcocite in the veins, inasmuch as primary chalcocite is believed to have originally extended to an elevation higher than the present ground surface. It follows, therefore, that to some extent primary chalcocite has been subjected to the action of atmospheric agencies along with the associated primary vein minerals. The result has been a sooty glance enrichment of the primary minerals of the ore among which there existed massive chalcocite.

Occurrence of Primary Chalcocite

The observed facts which have led me to the conclusion that primary chalcocite exists in large quantities in the Butte veins may be briefly stated as follows:

1. The occurrence of chalcocite in great abundance at levels 3000 ft. or more from the surface.
2. The intimate association of chalcocite with bornite, pyrite, and enargite in such a manner that all must be regarded as having been deposited at the same time and under similar conditions.
3. Chalcocite is found at all depths without regard to surface topography, which fact tends to show that no relation exists between the occurrence of chalcocite and present day downward seeping waters.
4. Chalcocite occurs in absolutely dry veins and ore-shoots at deep levels, and in many instances large bodies are cut by older faults, a fact further tending to show that this copper mineral is an old one and in no way genetically related to the present

*From 'Ore Deposits at Butte, Montana,' in *Trans. Amer. Inst. Min. Eng.*, August 1913.

day or a former similar underground water circulation.

5. Chalcocite directly replaces altered granite at deep levels. The power of cold meteoric waters to effect direct replacement of granite in quantity is seriously questioned.

6. No evidence is available tending to show that chalcocite is now being deposited in the veins, except within the sooty chalcocite zone. On the other hand, where positive evidence on this point is obtainable, it indicates a tendency of the massive chalcocite to alter to bornite and chalcopyrite under present groundwater conditions.

Secondary Chalcocite

As outlined in the discussion of the formation of sooty chalcocite, the facts plainly show that secondary chalcocite has resulted from downward seeping sulphate waters, and there can be no doubt that this mineral was in the active process of formation at the time the first mine openings were made in the copper veins. Concerning massive chalcocite of the deeper levels, however, there are important reasons for believing that it is in no way related genetically to the present existing meteoric groundwater circulation, or with any water circulation system of meteoric origin, but that, whatever the source, its time of formation must be referred to a relatively old mineralization period. The Rarus fault sharply cuts the important ore veins, displacing them hundreds of feet, so that in the intersected veins the possibility of surface waters effecting an enrichment of the truncated portion of the veins lying beneath the fault is extremely remote. The upper displaced segment of the O'Neill vein, for example, is no richer in chalcocite than the sub-fault segment, excepting within the chalcocitization zone directly beneath the oxidized zone. It is evident that the descending sulphate waters moving down the upper segment could not possibly reach the lower segment, and there is no indication of an enrichment of the upper segment where it meets the Rarus fault. The moving waters did not enrich the fault, as it carries no ore, neither did these solutions spread out to other veins cut by the fault. What is said here regarding the O'Neill vein is equally true of all the veins intersected by the Rarus fault. In examples of this character where possible source of the supply of the sulphate waters has been effectually cut off from the lower parts of the veins by intervening faults, it becomes evident that the chalcocite of the lower segments either had its source in uprising solutions or else it was deposited from a descending water circulation existing long prior to the appearance of the fault, and possibly far removed from the conditions as we now know them.

Age of the Deposits

Following this line of reasoning, it is possible, as will be later shown, to prove that chalcocite, other than the sooty variety, is a comparatively old mineral, and that it was deposited in great quantities prior even to the faults of the Steward system, which in themselves carry important bodies of ore composed of enargite, bornite, sphalerite, barite, galena, and other well known primary minerals.

In the No. 16 vein, a mineralized fault of the Steward system of the Rarus and Tramway mines, extensive bodies of chalcocite-enargite ore are sharply cut by the Rarus fault. These orebodies are in the form of the characteristic fault-vein ore-shoots, and actual development proves that they do not extend upward to within 1100 ft. of the surface, the higher portions of the fissure being absolutely barren of ore or gangue minerals. Like the chalcocite ores of the O'Neill vein above noted, the No. 16 vein ore-shoots were formed long prior to the Rarus fault. The altered condition of the crushed zone of the Rarus fault, the presence of much disseminated pyrite and quartz, together with the fact that a later fault (Middle) cuts and displaces the Rarus fissures, tend to show that geologically the Rarus is not a recent fissure, therefore the water circulation responsible for the chalcocite older than the Rarus fault must be far removed from the meteoric groundwaters of today.

Relation to the Steward Fault

Going further into the history of chalcocite, certain facts seem to indicate, if not definitely prove, that chalcocite existed as a vein mineral prior to the Steward fault period. In the ore breccia of the Gagnon mine fragments of older vein matter containing chalcocite are of common occurrence. The Steward fault fissure is of later origin than the breccia and the breccia is much squeezed and faulted where they come in contact. These angular ore fragments are within and form a part of the original breccia and they are plainly not of secondary origin. They are not breccias resulting from Steward faulting or any other fault movements, but they were formed in the same manner as the Mountain View breccias and probably at the same time. These ore fragments represent a period of mineralization of an earlier date, and they are not drag ore, but pieces of older vein which have fallen into open cracks.

The Blue Vein Fissures

In tracing the formation of earlier chalcocite, attention must be given to the remarkable ore-shoots of the Blue vein fissures, of which the great orebodies of the Jessie, Edith May, High Ore, Skyrme, and Blue veins are examples. It is a significant fact that many of the largest and most important rich chalcocite-enargite ore-shoots in these veins do not extend upward to within from 500 to 800 ft. of the surface. Not only do the copper minerals fail, but the common gang minerals, quartz and pyrite, drop out, so that the ore-shoots are capped by hundreds of feet of barren crushed granite and fault clay marking the plane of movement. In two instances, notably in the Jessie and Blue veins, ore-shoots reach the surface, but in these cases the upper 500 ft. of the shoots differ materially in mineralogical composition from the richer ores at greater depths.

A study of the composition and structure of these remarkable ore-shoots indicates that the minerals forming them have had a common origin. They are not connected or related in any manner with cross-fissuring or later faulting. The Blue vein ore-shoots

do not occur at the intersections with older quartz, pyrite veins, but, on the contrary, curiously enough, they are almost universally found in the intervals between the important older veins. No apparent relation exists between the Blue vein-shoots and the later Steward faults; in fact, repeated observations of such intersections show beyond question that the ore-shoots were in existence prior to the appearance of the Steward faults. It is next to impossible, however, if not entirely so, to determine what amounts, if any, of the minerals composing the Blue vein ore-shoots were added at a period immediately following the appearance of the Steward fissures. Ore-bearing solutions traversing the Blue fissures, after the Steward faulting began, did not necessarily originate through the later fractures, nor did solutions passing along Steward fractures necessarily find their way into the Blue veins. In both cases the circulation was confined largely to irregular zones within the fissures themselves, which are now marked by the positions of the ore-shoots. The intersections of Blue vein ore-shoots rich in chalcocite by Steward fissures are numerous, and, from the evident lack of influence on the mineralogical character of the ore, I am led directly to the conclusion that chalcocite did exist in large quantities in the Blue vein prior to the Steward faults.

Origin of the Early Chalcocite

Assuming for the moment that the above inference is the correct one, the difficulties met with in an attempt to ascribe a secondary origin to this early chalcocite are numerous and of vital import. At the close of the Blue vein period (which period is assumed to be the time elapsing between the beginning of Blue vein movements and the beginning of Steward faulting), it is fair to assume that the ground surface was much higher than at present, necessitating, therefore, a former extremely deep meteoric groundwater circulation to reach chalcocite orebodies of the Blue veins now found more than 3000 ft. from the surface. When one considers the rate of the downward invasion of the oxidized zone, it is almost inconceivable that down-seeping sulphate waters could have formed the extensive chalcocite orebodies found at these depths. The time required would be enormous, and furthermore, the fact must not be lost sight of that under conditions favorable for sooty chalcocite formations, as we know them, a very large part indeed, if not all, of the copper of the descending sulphate waters is deposited as secondary chalcocite before a maximum depth of 1200 ft. below the zone of oxidation is reached.

There is another important point inviting attention, relative to the probable condition of the underground circulation existing during the time of formation of the Blue vein ores and during subsequent periods extending to the present time. It is a self evident fact that meteoric waters could not have descended to great depths along veins, faults, or fissures at a time when appreciable quantities of waters, presumably deep seated, were ascending through such channels. It is a reasonable assumption, then, that no important downward movement of meteoric waters took place in the Butte fissures

until after the cessation of movement of the up-rising solutions from which were deposited the primary ores. It is not unreasonable to believe that some surface waters did reach these channels of up-rising waters at comparatively shallow depths, not, however, by direct descent along fissures through which deep seated waters were ascending, but by a downward lateral movement through neighboring fissures adjacent to the main trunk channels. As has been formerly pointed out, however, the movement of cold surface waters through normal granite is scarcely appreciable, and it is therefore extremely improbable that such waters could have influenced chemically, physically, or in any way whatsoever the action of the deep seated waters as they moved upward through the fissures depositing minerals undoubtedly derived from deep seated sources. The occurrence of undoubted primary ores, or quartz, pyrite, sphalerite, galena, and rhodochrosite, together with enargite, bornite, and chalcocite, in faults of the Steward system which are known to cut and displace chalcocite orebodies in the Blue and older vein systems, is conclusive proof that ascending solutions depositing primary ore continued in action long after the formation of the Blue vein chalcocite. It is probable that ascending waters continued to traverse the Steward and older fissures for a considerable length of time after the primary Steward ores had formed; in fact, it is not at all improbable that the alteration of the granite and deposition of pyrite in the Rarus fault resulted from ascending waters.

If an early circulatory system existed similar to that above assumed, it is difficult to understand how meteoric waters could have been active enough to transport large quantities of mineral from the oxidized zone to great depths at any period prior to the complete cessation of the upward movement of the primary ore solution. The time of cessation must have been as late as the end of the ore-forming period of the Steward fault veins, and possibly as late as the Rarus fault, both of which are known to be later than much of the chalcocite of the Blue and Anaconda veins.

Chalcocite of the Lower Levels

The chalcocite of the deeper levels, or in a general way the massive chalcocite of all the veins, bears no definite relation to the present surface topography. This is in marked contrast to the occurrence of sooty chalcocite known to be of secondary origin. The tops or apices of many rich massive chalcocite orebodies or shoots are found at depths ranging from 100 to 1500 ft. from the surface. The size and richness of the orebody are in no way indicated by the depth of the zone of oxidation; in fact, many of the largest ore-shoots of the fault veins are capped by 500 to 800 ft. of barren crushed granite and fault clay having an oxidized zone of less than 25 ft. in vertical extent. In the quartz-pyrite veins of the Anaconda system where the development of secondary glance is greatest, there is an apparent close relation between the depth of oxidation and the quantity of sooty chalcocite found below. A deep zone of secondary chalcocite is certain to be found below a deep zone of oxidation,

while a shallow zone of oxidation is accompanied by an unimportant development of sooty chalcocite below. If a secondary origin is assumed for the chalcocite orebodies whose tops or apices are separated from an extremely shallow oxidized zone by hundreds of feet of barren crushed granite, the question as to the source of the copper to form the chalcocite becomes of vital interest.

Source of the Chalcocite

Where the ore-shoots do not extend upward to the oxidized zone it does not appear possible that the source of the chalcocite could have been at a point higher than the top of the ore-shoot, for there is no evidence, direct or otherwise, that copper-bearing mineral of any character ever existed in the eroded and oxidized portions of the vein. The marked absence in the upper portions of many veins of an adequate source of supply for the copper found at great depths in the form of chalcocite is a common feature of these ore deposits. This is true not only of the fault veins, but in many of the veins of the Anaconda system. In the tramway and Leonard mines, for example, immense chalcocite-enargite orebodies 50 to 200 ft. thick, belonging to the Anaconda vein system, have been developed between the 1200 and 2000-ft. levels. From the 1200-ft. level to the surface these orebodies are represented only by small veins from 2 to 6 ft. in thickness, carrying but small amounts of copper. Indeed, in many instances the identity of the vein is entirely lost as the higher levels are approached. In nearly every case the oxidized zone capping the big orebodies of this district is shallow, and even if it be assumed that hundreds of feet of vein have been eroded, such eroded portions represent a source entirely inadequate to account for the chalcocite found below.

In the Shannon vein (belonging to the Anaconda system) of the West Colusa mine, the orebodies of the upper levels were of tremendous size, particularly in the region immediately underlying the oxidized zone, where there occurred a big development of sooty chalcocite. It is significant that although the vein continued big and strong in depth, with every condition favorable for secondary enrichment, the vein became poor rapidly in depth, portions of it at the 900-ft. level being too low grade to mine. Many other examples might be mentioned where old quartz-pyrite veins have been broken by later faults, and all conditions seem ideal for the formation of chalcocite ores in depth, but, other than the sooty glance enrichment, no notable addition of chalcocite has taken place.

The Mountain Chief Ore-Shoot

An interesting occurrence of chalcocite is found in the Mountain Chief ore-shoot of the Jessie vein, belonging to the Blue fault system. The oxidized zone is extremely shallow, being not more than 25 ft. deep at any point in the vein. The ore-shoots have been opened by continuous workings from the surface to the 2200-ft. level. There is a marked difference in mineralogical composition of these ore-shoots between their upper and lower portions. The change is found to take place at a depth of from

500 to 800 ft. from the surface. Some of the shoots do not extend entirely to the oxidized zones. The line may be drawn to mark approximately the elevation at which the change takes place. Above it the ore is an intimate mixture of quartz, pyrite, and chalcopyrite, the latter mineral occurring in abundance. Sphalerite and rhodochrosite are also present in considerable amounts. In the Mountain Chief mine one shoot extends entirely to the surface, where it is oxidized to a rich ore composed of cuprite and iron oxides. Immediately below these rich oxides there is but a slight development of secondary chalcocite, occurring as thin films coating the chalcopyrite and pyrite. At about the line suggested, within a vertical distance of from 50 to 75 ft., there is almost a complete transitional change from chalcopyrite ore to an ore consisting of chalcocite, bornite, enargite, pyrite, and quartz, with only small amounts of chalcopyrite. This character of mineralization has continued to the deepest levels yet opened, although there are some variations in the relative amounts of the minerals present. The development of chalcopyrite seems to take place only in the high levels or at the waning ends of the ore-shoots, indicating possibly that under certain conditions it is a lower temperature mineral than either enargite or chalcocite, assuming for the moment that all three are here of primary origin.

Surface Water Theory

In this particular example it is impossible to conceive of a surface water origin for the chalcocite lying below the chalcopyrite capping. There certainly is no apparent adequate source for the copper. Where the chalcopyrite ore suffers oxidation the larger part of the copper is held in the oxidized zone as an oxide or carbonate, and, even assuming that a part of the copper was carried downward, it is quite impossible for me to believe that it could have remained in solution while passing downward over the chalcopyrite-pyrite ore, to be later deposited as chalcocite from 800 to 2200 ft. below the surface.

As already stated, many of the Butte veins have but slight oxidized zones, accompanied by sooty chalcocite zones of small vertical extent separated by hundreds of feet of barren vein from the chalcocite ores below. In such instances it is impossible to trace any genetic relation between the meteoric water circulation and the chalcocite commonly occurring at depths greater than 1000 ft. Where, however, as in the case of most of the quartz-pyrite veins of the Anaconda system, an important chalcocitization zone exists associated with massive chalcocite ores, and is underlain at greater depths by large quantities of chalcocite not associated with sooty chalcocite, it is, perhaps, reasonable upon first thought to suppose that all the chalcocite of both higher and lower levels has had a common origin. The early prominence of the copper veins of this class has been largely responsible for the former general belief in a secondary origin for the chalcocite in the Butte veins.

Changes in the Oxidized Zone

The changes which occur in the oxidized zone of the old copper-bearing quartz-pyrite veins in Butte are due to processes which act slowly. The invasion

of the oxidized zone downward into the sulphides took place at an extremely slow rate, and in view of this fact it must be admitted that the sulphate solutions originating at the sharp contact between the oxides and sulphides were extremely dilute. The chemicals added to these downward seeping surface waters through the oxidation of the sulphides are chiefly copper and iron sulphates, and possibly small amounts of free sulphuric acid. These cold surface waters, after taking up their burden at the oxide-sulphide contact, pass immediately downward along the vein, or partly through country rock, moving more or less constantly in direct contact with the pyrite and other vein sulphides. As is well known, the reaction between the sulphides and sulphate waters results in the formation of sooty chalcocite as a direct replacement of the sulphide attacked. These sulphate waters also attack the altered granite, resulting in greater porosity and in the formation of abundant kaolin. There is also a chalcocitization of the disseminated pyrite so common in the altered granite. In meeting already existing groundwaters below, a large proportion of which, although of meteoric origin, did not take copper into solution on their downward journey, the descending waters along the veins must become more and more dilute and certainly less active chemically as greater depths are reached. As a matter of fact, actual comparisons of the veins and granite of the upper and lower mine levels show conclusively that the downward-seeping waters actually become weak and inactive at not great depths below the surface, and it was due to this fact, in part at least, that C. T. Kirk was able to differentiate so clearly between the chloritic, sericitic, and kaolinitic alteration phases in the Butte granite.

It is extremely important to understand clearly this feature, because, apparently much more vigorous chemical processes have been active in the formation of the massive chalcocite of the deeper levels than were necessary for the formation of the secondary chalcocite of the higher levels. In the sooty chalcocite zone only sulphides are attacked and replaced by the chalcocite, while at greater depths massive chalcocite alone, or intimate mixtures of chalcocite, pyrite, bornite, and enargite, directly replace altered granite in quantities within and along the fault veins and veins of the oldest system. I believe that such replacements could not have been effected by dilute meteoric waters, which, in the act of reaching great depths, not only became extremely dilute and of doubtful activity, but they have been deprived wholly or in part of their copper in the regions of sooty chalcocite formation.

Reasons for Belief in Secondary Origin

The observed facts which have led primarily to the belief that the chalcocite of the Butte copper deposit is of secondary origin may be briefly stated as follows:

1. The chalcocite is often of a later age than the vein minerals with which it is associated.

2. In some instances the proportionate amounts of chalcocite in the veins have decreased rapidly with depth.

3. It has been abundantly proved at Ducktown, Morenci, Bingham, and in many other instances, that under certain conditions chalcocite is a product of descending sulphate waters.

4. The depth of the chalcocite enrichment in many of the Butte veins bears a definite relation to the depth of the zone of oxidation in the respective veins.

In an endeavor to solve the problem of the chalcocite formation, some investigations have been made. H. V. Winchell⁴ succeeded in producing artificially, under normal conditions of temperature and pressure, chalcocite identical in chemical composition and physical character with the sooty chalcocite of the Butte veins. His experiments seem to prove conclusively that the formation of chalcocite, of the 'sooty' variety, at least, is easily possible under the conditions of temperature and pressure found in the upper levels of the Butte mines. Similar conclusions have been reached by H. N. Stokes and others in the laboratories of the United States Geological Survey.

Investigations of Charles T. Kirk

Perhaps the most elaborate investigation of this subject was undertaken by Charles T. Kirk,⁵ who made careful chemical and petrographic analyses of the altered granite occurring in and along the Butte copper veins. He found that during the vein-forming processes the granite suffered great changes in chemical and physical character. These changes took place more or less gradually. He separated them into three general alteration phases, namely: (1) the chloritic phase, which marks the earliest stage of alteration; (2) the sericitic phase, marked by the development of great quantities of sericite through the further action of heated waters in (1); and (3) the kaolinitic phase, a change from the sericitic phase brought about through the action of descending sulphate waters or sericitized granite.

Phases (1) and (2), therefore, result from the action of deep-seated ascending waters; (3) is effected by the action of descending cold meteoric waters on phases (1) and (2). With these three alteration phases Mr. Kirk links certain generalized groups of minerals. He believes the early quartz-pyrite ores began to form with the early chloritic phases; that the copper mineralization during this and the succeeding sericitic stage was principally enargite, bornite, and chalcopyrite; and, lastly, that the chalcocite formation belongs entirely to the third or kaolinitic phase. He holds that kaolinite is wholly a product of cold meteoric water action and therefore the presence of it in deep levels indicates the presence of waters of meteoric origin. Many geologists, notably H. E. Gregory, dissent from this view and hold to the opinion that kaolinite may also be a product of ascending water alteration.

Relation Between Altered Granite and Chalcocite

It is to be regretted that Mr. Kirk did not give a

⁴Winchell, H. V., 'The Synthesis of Chalcocite and Its Genesis at Butte,' *Eng. & Min. Jour.*, Vol. LXXV, No. 21, pp. 783 and 784, May 23, 1903.

⁵Kirk, C. T., 'Conditions of Mineralization in the Copper Veins at Butte, Montana,' *Economic Geology*, Vol. VII, No. 1, pp. 35 to 82, January 1912.

series of direct comparisons between samples of altered granite taken both from the sooty chalcocite zone and the deep levels. Certainly there is much yet to be learned concerning the relation between the altered granite and chalcocite formation. Even assuming for the moment that meteoric waters have sunk to great depth in the Butte veins, accompanied by the formation of kaolinite at all levels, it does not necessarily follow that the chalcocite was deposited from such descending waters. It cannot be doubted that the sulphate waters descended to depths greater than the lower limit of the sooty chalcocite zone, but it is evident that while the chemical effect of these waters upon the granite at greater depths may have been of the same general nature as in higher levels, that is, kaolinization, the chemical action toward copper mineralization was entirely different. The chalcocite of deeper levels is not necessarily a replacement of a sulphide mineral as in the upper levels. Since the replacement of the pyrite by chalcocite in the higher zones is accompanied by the formation of ferrous sulphate and sulphuric acid, the descending waters passing below the sooty chalcocite zone still retain an abundance of dissolved iron sulphates and probably sulphuric acid to act on the sericitized granite, forming kaolin, as in the higher levels, but it is more than probable that the descending waters were entirely robbed of copper in the secondary chalcocite zone. The small amount of kaolinite present in the deeper levels as compared with the great abundance in the oxidized and sooty chalcocite zones indicates less activity, due either to dilution or to change in chemical composition of the solution.

From these considerations it is readily seen that the association of chalcocite with minor amounts of kaolin below the chalcocitization zone does not necessarily imply that both have resulted from the same solutions. The descending sulphate waters may still continue to form kaolin in regions of primary chalcocite after having deposited all of the copper burden in the region immediately below the zone of oxidation. It may not be difficult to understand meteoric waters reaching to unusual depths in the Butte veins, but I seriously doubt that such waters could retain copper in appreciable quantities after moving downward for hundreds of feet in direct contact with newly formed chalcocite and an abundance of pyrite.

Effect of Continental Fault on Water-Level

It is unfortunate that most of the granite samples used by Mr. Kirk in his investigations were collected from the Pittsmont vein, for the reason that this property is peculiarly situated with respect to the general topography of the district, and it is also in close proximity to the Continental fault, a fracture of comparatively recent occurrence. The effect of this fault upon the water-level and oxidized zone may be readily understood. The immediate effect has been to drop the former erosional surface and oxidized zone to a depth considerably below their former positions. The collar of the Pittsmont shaft at the present ground surface is about 400 ft. above former erosional surface. In the mine workings the shoots in zone is 250 to 300 ft. thick, measured downward from the former surface, and the sooty chalcocite belt is known to extend at least 500 ft. deeper. Summing up these figures, the result is reached that the deepest general working level of this mine (the 1200-ft.) is not more than 600 ft. below the zone of oxidation, or, as a matter of fact, scarcely below the zone of sooty chalcocite. When it is remembered that in the Mountain View mine the sooty chalcocite zone is 800 to 1200 ft. thick, one is forced to the conclusion that Mr. Kirk's samples do not represent conditions far removed from the direct influence of copper-bearing surface waters. The results of his work are extremely interesting and of value, especially his investigations concerning the alteration of the granite, but in my opinion he has erred in attempting to apply his method of reasoning to the chalcocite of deep orebodies of the Butte veins with which he is evidently unfamiliar. His results are valuable inasmuch as they further corroborate and establish, from a new point of attack, the conclusions already reached by others that the sooty chalcocite, and massive chalcocite to a limited extent, of the Butte deposits, have resulted from the work of downward seeping sulphate waters whose copper was derived from the oxidized zone.

Observations of W. H. Weed

W. H. Weed⁶ has set forth some facts which, in his opinion, tend to prove the secondary origin of the Butte chalcocite. He observes generally that the old quartzite-pyrite veins were originally of very low grade and they became commercially valuable through the later addition of enargite, bornite, chalcocite, and other copper minerals. He believes that this copper mineralization followed various periods of faulting, the enargite and bornite being the first to appear, probably contemporaneous in a general way with the Blue and Steward fault system. Chalcocite, which forms the bonanza ores of the district, is thought by him to have been almost entirely a product of descending sulphide enrichment processes, acting at great depths, however, only where the older quartz-pyrite veins were cracked and broken by faults, thus permitting a ready passage for the downward-seeping waters. He cites many examples of such intersections of faults and older veins in support of this view, and maintains that the old quartz-pyrite veins are workable only where thus fractured.

My own observations do not confirm Mr. Weed's conclusions as above outlined. Actual examination of a great many intersections of old quartz-pyrite veins by later faults have shown conclusively that as a general proposition the east-west veins are no richer at or near intersections with Blue vein faults than at other points along the vein, except in cases where the fault vein ore-shoots cross the older vein. It is extremely difficult to form even an approximate idea as to the extent of primary enrichment in the older veins due to the late faults of the Steward system. Mineralization processes were active in the early veins prior and subsequent to the Blue

⁶Weed, W. H., 'Geology and Ore Deposits of the Butte District, Montana,' Professional Paper No. 74, U. S. Geological Survey, p. 152, 1912.

vein period, so that it is impossible to determine, in the absence of any characteristic minerals, what influence was exerted by the later faults upon the older veins. As might be expected, the fault vein intersections are usually accompanied by a breaking and shattering of both the older vein and the country rock in the immediate vicinity, thus developing favorable factors tending to greatly influence ore deposition at such points. In any case, where a chalcocite enrichment of a vein of the Anaconda system is shown to have resulted from the influence of an intersecting fissure of the Blue or Steward system, there remains the strong probability that such enrichment is due to primary waters, if, as I believe, the primary chalcocite was deposited in great quantities, after the appearance of these faults, not only within the faults themselves, but in the fractured older veins.

Mining in Northern Ontario

By P. B. McDONALD

The rapid development of Cobalt was due to the fact that a railway ran through it, bringing in the supplies and taking out the ore. But Cobalt was the making of the Government railway in northern Ontario. With some show of truth, it may be said that the Government was the making of Cobalt. A mining region without railway facilities, no matter how rich it may be, is handicapped, almost paralyzed. The miner and prospector must have machinery, coal, and food supplies; they also must have railway facilities to transport the ore. In the absence of these advantages, a mineral region, except for placer gold mining, as in the Yukon, is almost worthless.

The Government Railway

North of Cobalt, the Government railway has failed to intersect another mining region, but traverses a clay belt which promises in the future to be a fine agricultural country, but some years will elapse before it is developed. At Larder Lake there have been some discoveries, and west of it, about five miles from the railway, is the new Kirkland Lake district, in which small but rich veins of gold ore are being worked. To the west of the railway, however, two large mineral areas have been opened which promise much. These are Gowganda and Porcupine. The former of these camps is laboring under a great disadvantage from lack of direct transportation. Porcupine has now good railway facilities. The result is that while Cobalt was a poor man's camp in the sense that it was easily accessible and cheaply mined, the poor prospector is being rapidly frozen out of the Gowganda district. Gowganda is a silver camp of large area, and it may be a surprise to the people to know that, notwithstanding the disadvantage of requiring the transshipment of ore at Elk Lake, Gowganda has shipped more ore in the past year than Cobalt did in the second year of its existence. Notwithstanding its poor transportation facilities, one mine alone has shipped thirteen carloads. While a large number of claims are staked out, and there

are fine surface showings over a large area, the enterprise of the miners is paralyzed by their inability to get supplies, coal, or machinery, as may be imagined, and the methods of mining obtaining there are crude. The operators are men of means who can provide the capital, but the unfortunate prospectors are forced to sell their claims because they can neither mine nor keep up the assessment work. Outsiders have shown no great disposition to purchase these claims. Nevertheless, a number of mines are being worked, and the showings are good. In one case rich ore has been mined at a depth of 150 ft., and another mine is down 200 ft. and in ore.

The New Wagon-Road

In 1909 it was expected that a branch of the Government railway would be built in, but nothing has been done. This year the miners' hopes were rewarded by the construction of a wagon-road, but of such superlative roughness that one ton of freight is more than a team of horses can haul over it. It has cost as much as \$1600 to market a carload of ore from Gowganda. Naturally, the ore must be very rich to stand such a tax. Fortunately, the present high price of silver and the possible further advance cover the big expense of mining and marketing the ore from some properties. With the extension of railways and improved transport facilities a period of increased production is anticipated.

Northern Ontario, to July 1, produced almost a hundred million dollars in silver—to be exact \$98,890,000. Of this production, all but one-tenth, or \$9,800,000, came from Cobalt, the latter amounts coming from the other smaller silver camps, chiefly Gowganda. Cobalt, it is to be remembered, is but in its eighth year. Half of the total has gone back to the shareholders in its mines. The camp is now turning out an average of \$100,000 every working day. No estimate can be made of the value of the silver in sight in the mines, but it undoubtedly runs into the millions; 10,000,000 oz. in one mine, 4,000,000 oz. in another, and 2,000,000 oz. in a mine of comparative recent operation. Cobalt has the record of American silver mining: seven and one-half years to produce nearly \$90,000,000 worth of silver.

Gold, for the first time in the history of Ontario, formed a substantial part of mineral production in 1912. In 1911 the output had a value of \$42,637; in 1912 the gold output increased to \$2,114,086. The greater part came from the mines of the Porcupine district, principally from the Hollinger and Dome, which came into full production early in the year. Other mines at Porcupine whose stamp-mills are now working are the McIntyre, Vipond, Jupiter, and McEnaney. Besides these mines at Porcupine, the St. Anthony mine at Sturgeon lake and the Cordova in Peterborough county yielded considerable bullion. The outlook is for a much larger production at Porcupine. The other gold camps in that locality, as Larder lake, Kirkland lake, Swastika, etc., have not yet reached a stage of steady output, although there are strong hopes of ultimate profit.

New Canadian Dredges

By AN OCCASIONAL CONTRIBUTOR

The Canadian Klondyke Mining Co. is operating four elevator dredges in the Bonanza basin near Dawson, Yukon Territory. The first one of these dredges, which is of 7½-cu. ft. capacity, was put in operation about 1907, and it has been operating continuously, excepting in the winter months. It is an electric-driven machine having a continuous bucket-chain and revolving screen. The next machine put to work was a 16-cu. ft. dredge built and put in operation in 1910. This was also an electric-driven machine, but it differed from the first one in that all motors are direct connected, doing away with the troublesome driving belts. Both of these machines were built and equipped by the Marion Steam Shovel Co., and they gave such excellent satisfaction that an order was placed in 1912 for two more 16-cu. ft. machines, which were finished in the spring of 1913. These last two machines were along the general lines of the one built in 1910, but carried many improvements, mainly along the line of convenience in operating and making repairs. These two machines are known as Canadian No. 3 and Canadian No. 4, and are exactly alike.

Difficulties in Landing the Machinery

The difficulty encountered and finally overcome in landing this machinery at the point of construction can be appreciated when it is remembered that the total weight of machinery as shipped from Marion, Ohio, was approximately 2,250,000 lb. for each machine, and due to the design, it was necessary to ship some pieces weighing as high as 25 tons. This was quite a task, as each piece had to be handled several times before finally landing at its destination, going as it did by rail to Vancouver, British Columbia, thence by boat to Skagway, from there by narrow-gauge railroad to White Horse, then down the Yukon river in small boats to Dawson and from there by rail to point of construction. The long distance shipped, as well as the numerous handlings, made the freight charges very heavy.

The hulls are constructed of timber throughout, each containing about 750,000 ft. of Oregon fir, all of which had to be shipped from Vancouver. The over-all dimensions of the hull are: length, 136 ft.; width, 56 ft. 8 in., with a depth of 14½ ft. at the bow and 12 ft. at the stern. Because there is 5½ ft. overhang at both sides, the deck itself is approximately 68 ft. wide, thus giving additional area for gold-saving tables.

Bucket Equipment

These dredges are both equipped with a continuous chain of 71 buckets. These are of approximately 16-cu. ft. capacity and 40-in. pitch, and are cast solid in one piece, excepting the lip, which is of manganese steel securely riveted to the bucket proper. Each bucket weighs about 4800 lb. complete. These buckets are carried by a ladder of the plate girder type, 97 ft. centre to centre of

shafts and weighing when complete about 108 tons. This weight includes the ladder structure itself, 17 ladder rollers which are bolted to the upper side of the structure, and the lower tumbler and shaft with bearings complete. The lower tumbler and shaft alone weigh about 14 tons. The total weight of the ladder with bucket-line attached is 275 tons, and adding about 50 tons for material, the total load to be carried by the suspension shaft and ladder tackle is about 320 tons. The ladder is handled by the ladder-hoisting machinery, consisting of a drum with suitable gearing, driven by a 200-hp. variable-speed induction motor. The bucket-line is driven by massive main drive machinery which is securely bolted to the inside tumbler framework. This machinery, including gearing and housing, weighs 162,000 lb. Power is furnished to drive this machinery by a 300-hp., variable-speed, induction motor, direct connected to the machinery.

Revolving Screens

The gold-bearing gravel is washed and separated in a revolving screen, which is placed at the centre of the hull aft. This screen is of the straight type, 50 ft. long and 9 ft. 9 in. diam., and is carried on two cast steel screen paths, one at each end, which are in contact with the driving and guide rollers. The driving is accomplished by friction contact at the upper end. This screen weighs about 172,000 lb., and under ordinary running conditions would contain from 30,000 to 40,000 lb. of material.

The gold-saving apparatus consists of a double bank of gold-saving tables extending the full width of the hull aft, having a combined area of about 5500 sq. ft. The upper end of these tables is fitted with cocoa matting, held in place by expanded metal, while the rest of the area is fitted with angle iron riffles. It is estimated that about 90% of the gold saved is caught in this cocoa matting. The waste material is taken from the screen and carried to a sufficient distance beyond the boat by a stacker belt, which is carried by a stacker 115 ft. long centre to centre of belt pulleys. This stacker is of box-girder type, weighing about 40 tons complete. The stacker belt is 48 in. wide, carried on troughing idlers on the return side by straight idlers, and is driven by a 50-hp. motor placed at the upper end together with the necessary driving apparatus.

High-Pressure Pumps

An immense volume of water is necessary to thoroughly wash the material as it comes from the bucket-line and at the same time carry it through the screen and over the tables. For this purpose a 14-in. high-pressure centrifugal pump, and 16-in. low-pressure centrifugal pump are used, the former being driven by a 150-hp. constant speed induction motor, and the latter by a 200-hp. motor of the same design. In addition to these pumps, there is a 4-in. high-pressure pump, direct connected to a 35-hp. induction-type motor, which is used for priming purposes and also for a general purpose pump around the deck.

The dredge is held in position while digging by two massive structural steel spuds, which are held

in suitable framework at the stern. These spuds weigh about 35 tons each, and are raised and lowered by means of the winches placed on the deck. These winches consist of eight drums arranged in pairs. From this machinery the bow and stern swinging lines are operated.

Another interesting feature of these dredges is the traveling cranes arranged to operate above the house and house framework. It is possible with these cranes to pick up material from a scow at the bow of the dredge and convey it to any desired position fore and aft. These are the only dredges in operation in this country which are equipped with this device.

Motors

All the motors on these machines are wound for 2200-volt, 3-phase, 60-cycle. The list includes the following: main drive, 300 hp.; ladder hoist, 200 hp.; screen drive, 150 hp.; winch drive, 50 hp.; stacker hoist, 35 hp. All are variable-speed induction motors. There are also the following motors, all of which are constant-speed induction type: 16-in. pump, 200 hp.; 14-in. pump, 150 hp.; screen drive, 50 hp.; 4-in. pump, 35 horse-power.

It is estimated that each dredge represents an outlay of about \$475,000 as it stands ready to run. It is therefore necessary, in view of the short working season, to keep them in constant operation. This is only possible by keeping a large stock of repair parts on hand, together with the necessary facilities for making quick changes of parts, and on the efficiency of this system depends, in a large measure, the success of such placer operations.

Bismuth-Tin-Wolfram Ores from Tasmania

*The ore of the Shepherd and Murphy mine at Moina is very complex, containing bismuth, tin, wolfram, a large proportion of pyrites, magnetite, and traces of molybdenite. The lodes, which are of pegmatic structure, continue for great length, but are comparatively narrow, averaging only 15 to 18 in. The wall rock is principally quartzite. A number of lodes have been proved. The mill has been altered considerably from time to time. Originally, the ore was crushed by stamps, but as the metallic content is in a state of loose aggregation, and can be recovered without fine crushing, a 16 by 9-in. jaw breaker is used, and a second one is shortly to be installed for crushing the oversize. The equipment includes rolls, trommels, jigs, Wilfley tables, Frue vanners, and canvas strakes. All the machinery is driven by water power, and the output is periodically affected by shortage of rainfall. The present season, for instance, has been rather a poor one in this respect, very little rain having fallen between Christmas and the middle of March. The concentrate, averaging 32 to 40 tons per week, carries an equal content of tin, tungsten, and bismuth. It is shipped to the Company's works in Launceston, and separated into marketable products by means of two Wetherill magnetic separators. The machines give three products. The first two magnets, 4 amperes, extract the magnetite, while the second

magnets, 14 amperes, separate the wolfram, leaving a final tin-bismuth product. Three products are being shipped, namely: wolfram firsts, assaying 70% tungstic acid; seconds, from the treatment of the pyritic material, averaging 63% tungstic acid; and a tin-bismuth mixture very low in tungstic acid.

A Home-Made Self-Loading and Dumping Water Skip

By H. E. WHARTON

A self-loading and dumping water-skip for taking water from shafts having a slight incline is made as follows. Take a piece of old smokestack about eighteen inches in diameter and eight or ten feet long, and put a hinged valve or clack in the bottom ten inches square. Then put a piece of 1½-in. pipe through the stack at about one-fourth the distance from the bottom for a trunnion, and a

SKIP AND DUMPING DEVICE.

bail on the top for a cable. The tracks used are made of 2 by 6-in. lumber with notches cut in them just above the top of the shaft to let the trunnion drop in when the skip lands. When the engineer slacks the cable, it dumps. The angle iron is fastened on the track as shown, with the counterbalance heavy enough to let the loaded skip drop in the notches. After dumping, the skip is hoisted a couple of feet and when it is lowered the angle iron will carry it over the notches.

The Broken Hill Proprietary produced the following in July:

Mine product, silver, ounces.....	160,978
Mine product, lead, tons.....	2,519
Purchased ores, silver, ounces.....	191,211
Purchased ores, lead, tons.....	3,855
Antimonial lead, tons (estimated).....	28
Zinc concentrate from flotation, tons.....	7,000
Metal contents:	
Silver, ounces	90,214
Lead, tons	524
Zinc, tons	3,227

*Abstract from *Mining and Engineering Review*.

Stamp-Mills of the Past

While stamp-milling was not the first form of crushing employed in the treatment of the precious metals, with its invention in the latter part of the fifteenth or early sixteenth century it may be said that the foundation of modern milling practice was laid. The first crushing appliances as described by the ancient authors, the remains of which are seen in the old Greek and Roman mills which are scattered over Europe, were hand mortars and millstones of the same pattern as those used for the grinding of wheat. In Beckman's

AN OLD OAXACA STAMP-MILL.

'History of Inventions,' the following has been written regarding the early practice and first appearance of the stamp: "In the year 1519 the process of sifting and wet stamping was established at Joachimsthal by Paul Grommestetter, a native of Schwartz. The machine was named the Schwarzer. Soon after this there was erected, in 1521, a large stamp-milling works at Joachimsthal, and the process of washing was begun. In 1525 this method was introduced at Schlaekenwalde by Hans Pörtner, and in the Harz district at Wildenmann, by Peter Philip, about the year of 1524." Ruins of these old mills are still to be seen in the Harz mountains, Transylvania, Mexico, and other parts of the world.

The First Mills

In discussing the early stamp-mill, Agricola, as translated by H. C. Hoover, describes it in an interesting manner. The ore is crushed with iron-shod stamps, in order that the metal may be separated from the stone and the hanging wall rock. The machines which miners use for the purpose are of four kinds, and are made by the following method. A block of oak timber is laid on the ground and in the middle of this is fixed a mortar box. The front of the box, which might be called a mouth, is open; the bottom is covered with a plate of

iron, each end of which is wedged into the timber with broad wedges, and the front and back part of it are fixed to the timber with iron nails. To the sides of the mortar above the block are fixed two upright posts, whose upper ends are somewhat cut back and are mortised to the timbers of the building. Two and a half feet above the mortar are placed two cross-beams joined together, one in front and one in the back, the ends of which are mortised into the upright posts, already mentioned. Through each mortise is bored a hole, into which is driven an iron clavis; one end of the clavis has two horns, and the other end is perforated in order that a wedge driven through, binds the beams more firmly. Three and a half feet above the cross-beams two other cross-beams of the same kind are again joined in a similar manner; these cross-beams have square openings, in which the iron-shod stamps are inserted. The stamps are not far distant from each other and fit closely to the cross-beams. Each stamp has a tappet at the back, which requires to be daubed with grease on the lower side, that it can be raised more easily. For each stamp, there are on a cam-shaft two cams, rounded on the outer end, which alternately raise the stamp, in order that by its dropping into the mortar, it may with its iron head, pound and crush the rock, which has been thrown under it. To the cam-shaft is fixed a water-wheel whose buckets are turned by water-power. Instead of doors, the mouth of the mortar has a board, which is fitted into notches cut out of the front of the block. This board can be raised in

order than when the mouth is open, the workmen can remove with a shovel the fine sand and likewise the coarse sand and broken rock into which the rock has been crushed; this board can be lowered, so that the mouth thus being closed, the fresh rock thrown in may be crushed with the iron-shod stamps. If an oak block is not available, two timbers are placed on the ground and joined together with iron clamps, each of the timbers being six feet long, a foot wide, and a foot and a half thick. Such depth as should be allowed to the mortar is obtained by cutting out the first beam. In the bottom of the part thus dug out, there should be laid a very hard rock a foot thick and three-quarters of a foot wide; about it if any space remains, earth or sand should be filled in and pounded. In the front, this bedrock is covered with a plank. When the rock is broken it should be taken away and replaced by another. A smaller mortar having room only for three stamps may also be made in the same manner.

Stamp Stems

The stamp stems are made of small square timbers nine feet long and a half a foot wide each way. Where the head of the shoe is enclosed in the stem, it is bored through, and similarly the stem itself is pierced and through the opening of each

there passes a broad iron wedge, which prevents the head falling off the stem. To prevent the stamp head from becoming broken by the constant striking of fragments of ore or rocks, there is placed around it a quadrangular iron band a digit thick. Those who use three stamps, as is common, make them much larger. The iron shoe of each has a length of over two feet; at the lower end it is hexagonal. There are some who make that part of the head which is enclosed in the stem barbed and grooved, in order that when the hooks have been fixed to the stem and wedges fitted in the grooves, it may remain tightly fixed, especially when it is also held with two quadrangular iron bands. Some divide the cam shaft with the compass into six sides, others into nine; it is better for it to be divided into twelve sides in order that successively one side may contain a cam and the next be without one.

Old and New Mills

So Agricola has described the progenitor of what has come to be the standard crushing machine of today. It will be seen that an analysis of this primeval prototype shows the identical features which are embodied in modern practice, and the process of evolution has confined itself to the perfecting of mechanical and structural details. The over-shot wheel has been replaced by the motor, the square stems have been made circular and of steel, the falling weight has been increased, mechanical feeders have been installed, the shoes and dies have been altered, the shape of the mortar box has been changed, and the direct fall has been supplemented with a grinding movement, but the details as to principle remain the same. The half-tone shows one of the forefathers of the Mexican milling practice, built in one of the out-of-the-way districts of Oaxaca; it still stands as a monument to the millman of yesterday, who by axe, timber, and grit fashioned this crude mortar and added another iota of bullion to the world's store.

Use of Gasoline Motors in Coal Mines

By A. F. KING

*In shape and appearance the gasoline locomotive closely resembles the electric, except that it has no trolley pole. The larger types require more height than an electric motor of the same weight. Rotation is always in one direction, so that the reversing is done by means of clutches and mitre gears. They are usually constructed so as to run on full and on half speed. Each motor is equipped with what is called a carburetor. The office of the carburetor is to properly mix the air and the gasoline in the cylinder. They are also equipped with an electric lighting device, which is so connected as to operate from a storage battery when the motor is starting, and thereafter from a magneto. Some manufacturers also equip the motor with absorption chambers, the types and capacities of which differ with the size of the motor. These absorption chambers are intended to absorb the carbon dioxide

(CO₂) generated, and to cool the gases given off. It is also claimed that this absorption chamber is a protection against the ignition of explosive mine gas or coal dust in case the engine 'back-fires.'

The repairs are said to cost about the same as for electric motors of the same power, but on account of the gasoline motor having reciprocating parts, I am inclined to believe that they cost more.

Advantages of the Gasoline Motor

The advantages of the gasoline motor are:

1. That no power-plant is needed to operate them.
2. That there are no transmission wire lines or pipe-lines needed.
3. The use of the motor is not affected or interrupted by short circuits, bursted pipe-lines, or drains upon the transmission lines by other motors.
4. No trolley lines, hangers, bonds, or cables are required.
5. It aids in the humidification of the mine air.
6. It is safer than a trolley wire equipment.
7. No time is lost in handling the trolley pole or wires; and in gathering it is unnecessary to attach and detach either transmission or haulage cables.

The disadvantages of the gasoline motor are:

1. That in the use of gasoline in the mines there is an element of danger, from the fact that it readily volatilizes, and when mixed with air forms a very explosive gas.
2. The combustion of gasoline in the combustion chamber extracts oxygen from the mine air.
3. Carbon dioxide and free nitrogen are the products of the perfect combustion of gasoline.
4. The carburetor is usually adjusted to furnish, as nearly as possible, the proper mixture of gasoline vapor and air when the motor is doing its heaviest work, so that if it be assumed that, under these conditions, perfect combustion is obtained, it is evident that when the engine is running with the motor standing, or when it is doing light work, imperfect combustion results, which means that carbon monoxide (CO) is given off.
5. I am of opinion that the absorption chambers do not eliminate all of the carbon dioxide which is produced, nor do they prevent the carbon monoxide or free nitrogen from being given off.
6. When the coal must be cut by mining machines, a power-plant, though not necessarily so large, must be operated and maintained, and transmission lines, both outside and inside the mines, must be erected and maintained.
7. The gasoline motor costs from 25 to 50% more than the electric motor of the same power.
8. It is also said that, due to its having but two speeds, the gasoline motor will not start as large a trip as the electric motor.
9. One complaint I have heard is that it will not take an overload, as do electric motors; but it seems to me that the tractive effect in either case is dependent upon the weight of the motor.
10. At the present time the gasoline motor cannot safely be used in a gaseous mine.

*Read before the West Virginia Coal Mining Institute and reported in *Black Diamond*.

Thirteen tons 1035 lb. of silver bullion was shipped from the Belmont mill at Tonopah in August.

Slime Agitation

By H. B. WRIGHT

*As the agitation of slime is of such importance in the present-day treatment of gold ores, the following brief particulars and the accompanying sketch of the Wright-Jaentsch centrifugal aerator, as used at the Great Boulder Perseverance mine, may be of interest.

The principle of the machine is based upon centrifugal force. It is of simple construction, works automatically, and the cost of installation and maintenance is trifling. The pipes, any number of which may be used, act essentially as simple forms of centrifugal pumps and operate at whatever speed is

WRIGHT-JAENTSCH CENTRIFUGAL AERATOR.

required. Practical tests have shown that a satisfactory rate is when the outside ends of the pipes have a circumferential speed of 350 ft. per minute. Four pipes, each with a diameter of 6 in., have given good results. The pipes should have an inclination of 45° from the horizontal; anything less than this may induce silting. When the ends of the pipes are just submerged, the greatest pumping effect is attained, for the reason that there is then no hydrostatic head to be overcome.

Treatment of Roasted Ore

In the treatment of roasted ore with cyanide solution, following pan and tube-mill grinding, it has been ascertained from a number of tests, conducted over a long period, that a vat fitted with this pipe system shows an increase of 7.5% of gold dissolved in the vats over that of the ordinary form of mechanical agitator. The following results were obtained by assaying the gold-bearing cyanide solutions from one agitator fitted with ordinary stirring gear and another equipped with the centrifugal circulating pipes. The pulp, after grinding and amalgamation, was divided as equally as possible and run into the separate vats, in order that any differences due to roasting would exercise the same relative influence. The average number of grains of gold per ton of solution in 24 charges in an agitator with stirring gear was, when filled, 117 gr., and when discharged 117.2 gr.; and in an agitator with centrifugal pipes was, when filled, 115.9 gr., and when discharged 120.3 grains.

The mean average results from the ordinary agi-

tator show that there is only 0.17% of gold dissolved in from one to two hours' agitation, whereas in the case of the pipe agitator there is 3.71% increase, or 3.54% in favor of this type. The ratio of solution to ore was 2.14 to 1, which gives 7.5% per ton of ore. It has frequently been observed that prolonged agitation shows gold being precipitated from the pulp solutions. With the ordinary stirring gear as used, it was proved that in 24 charges no less than eight showed gold precipitated, and in the case of the pipe agitator there was none. The percentage strength of the cyanide solution during these tests contained 0.085 total cyanide and 0.065 free cyanide, the standard found necessary to give the best economical results.

Twenty-three of these vats are in operation at the Great Boulder Perseverance mine; each vat is 20 ft. in diameter and 4 ft. 6 in. deep; the arms are rotated at 6.7 r.p.m., and 3 hp. is required to operate each vat.

$$\text{From the formula} = P \frac{W \times V^2 \text{ lb.}}{g \times r}$$

Where P = the centrifugal force in pounds.

W = the weight of the body in pounds.

V = the velocity of the body in ft. per sec.

g = gravity's acceleration.

r = radius from centre of motion to centre of gravity in feet.

Taking W = 60.7 lb. (specific gravity of pulp at 1.25.)

V = 4.9 feet.

g = 32.

r = 7.

it is found that the centrifugal force exerted is 61½ pounds.

Hammer-Drills

*The hammer type of drill is a natural air saver, and it is in the design and construction of this type that air economies may be effected safely and without sacrifice. It represents the evolution of the rock-drill from the piece of steel struck by a hammer through the various stages of percussive machines back again to the hammer-driven blow upon the steel, the difference being only that the blow is a rapid power blow. A hammer-drill is economical in air consumption because, in the first place, it reciprocates a light plunger which weighs only a few pounds, while with the piston-drill not only must the heavy piston be thrown backward and forward at high speed, but it carries with it the steel and bit. In hammer-drills the power is utilized, not in overcoming the inertia of a heavy body, but in compensating for that inertia through the high speed of a light body. A heavy mass moving slowly may give the same impact of blow as a light mass moving rapidly. The effective work done is represented by the weight multiplied by the velocity. The same effect may be produced by subtracting from the weight and adding to the velocity, or vice versa. In a piston or percussive drill, velocity is limited, while in a hammer-drill it is practically unlimited, and here is where the great possibilities of hammer-drills lie.—W. L. Saunders.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Government Prospecting

The Editor:

Sir—The recent communication by Albert Burch touches upon the most important subject relating to the future of mining. As prospecting is essentially work upon the ground and not at the office desk, it may be easy to overdo the subject in print, but a few remarks seem in order, especially as the first writer invites criticism. The question of Government land, especially in the West, is one which has afforded opportunity for considerable discussion by politicians and others. New suggestions come so fast that it is a remarkable person who can map out a course on the subject and adhere to it in all details. The educators who approve of study simply for mental gymnastics should certainly admire the subject with its recent turns.

After listening to the heated arguments about our Eastern brothers who have 'squandered their birthright of resources' and now wish to share in those of the 'undeveloped West,' a proposal for Government prospecting comes as a relief. Ordinarily it has been thought that the federal government should be called upon to do work falling in two classes; first, that which was so large or upon which returns would be so long delayed that private enterprise could not well embark; second, work which so intimately affected the common welfare that private enterprise could not be trusted to do it. Any new proposal for Government activity should fall in one of these classes to receive popular approval. Let us examine the subject of prospecting for the more valuable metals and see if it will fall into such classification.

Scarcity of Prospectors

That prospectors are more rare than formerly, there can be no question, and one obvious reason is that it has gradually become more difficult to find a deposit of value. The subject is frequently dropped with no further attempt at explanation. However, there may be other reasons. The prospector, to whose description no greater inaccuracy can be applied than the continued use of the word 'old', is an ordinary man with some knowledge of minerals and possessed of the spirit of adventure. Any proposal as to his work should rest upon such an assumption. During the development of the West many fields of activity besides mining have opened, and if the business of prospecting is being abandoned, it is partly due to competition or opportunities offered by other industries because the men fit for prospecting have disappeared. To meet competition in this, as in all other lines of endeavor, better or at least equal opportunities for gain must be presented. Now, certainly, the chance for gain in prospecting is arbitrarily fixed by nature; that is, a prospector can only find what already exists,

and this chance has been steadily reduced as each find has taken place in the past. Therefore, an effort to meet competition cannot be made along the line of increased probable reward. However, an effort can be made at the other end; that is, by decreasing the probability of loss. Nearly every Western metal mine working a crew of as many as fifty men has probably a dozen men who possess the three prime requisites of a prospector, namely, a good physique, spirit of adventure, and common sense, supplemented with some knowledge of minerals. These men are fairly sure of saving a certain amount of money every day that they work steadily, and many of them have families, which makes it absolutely necessary that they take what appears to be a sure profit. Nearly all the mining companies working such a crew of men regularly are making yearly profits. Would it not seem most reasonable to ask those who are directly profiting from mineral deposits to assist in stimulating the business of finding other deposits to replace those being exhausted? With the preceding outline of conditions in mind, there are, fortunately, all of the necessary tools at hand to proceed.

The Mineral Laws

With the present mineral laws, Uncle Sam is in the position of offering to any citizen the opportunity to search for any minerals, wherever some one else has not already appropriated them. In case of discovery, our liberal Uncle does not require anything in return, unless the discoverer wishes to gain a more secure title by obtaining a patent at a comparatively small cost. To ask the old gentleman to go to greater lengths of liberality seems absurd. On the contrary, it would not be out of order should he call for an accounting from his nephews. Probably the facts disclosed would warrant him in hereafter refusing to allow many of them to hold ground simply by doing assessment work to the amount of \$100 per year. Especially when he finds that the supposed expenditure frequently dwindles to about \$25 worth of actual beneficial work. Many mining concerns spend larger sums searching for new properties, frequently covering an entire continent with meagre or negative results. Such searches entail great expense for salaries and traveling. Generally, they consist in thoroughly examining deposits already known and slightly developed. Could not such an exploration policy be supplemented by a more minute search nearer home, where there must be some other deposits besides the ones now working? Many of the workmen at operating mines would welcome an opportunity of spending a part of the year in prospecting if they were assured of steady work during the remainder of the year together with living expenses while in the field. It would be easy for the company to fulfill both these conditions, when it is considered that a prospector's monthly expenses, if within 100 miles of the home camp, could not with the wildest dreams of camp luxury exceed \$50, and should be nearer half that amount. Five men for six months during a year would cost, at a maximum, only \$1500, and with a liberal addi-

tion for 'overhead expenses' the expenditure would be less than \$3000. This sum is equivalent to mining about 600 ft. of drift, and many companies do not hesitate to do that much dead work in the hope of finding something new. Many details, of course, remain to be adjusted, such as terms upon which the men are to work, and methods of supervision. When it is considered that so many old miners are willing to take leases in old properties where the companies hesitate to prospect, and are then satisfied with little better than wages, it is reasonable to suppose that terms could be arranged satisfactorily. An agreement giving a certain percentage of gross production to the discoverer, or even a flat sum as low as \$5000 for a valuable claim, would be possible. Supervision would be simple, and should be left to one competent man—engineer, superintendent, or foreman—who should work out details of terms and territory, and regularly visit all the men, direct their efforts, and take plenty of samples, giving the results of assays to the prospector. There are plenty of men who would do this part of the work and take part of their pay from discoveries.

As before stated, there is no need to ask for governmental restrictions to reserve territory. A large group of claims could be located, if desired, before the work commenced, which would be ample protection. State laws as to location work would be a factor to be considered. Instead of asking the federal government to do the prospecting and challenging the Geological Survey to show enough courage to undertake the responsibility, it may be that some people familiar with conditions will ask for evidence of past performances indicating that the Survey could accept the responsibility even should its members be so inclined.

R. P. MACLAUGHLIN.

San Francisco, September 3.

Forest Service

The Editor:

Sir—In your magazine of June 28, in commenting on the letter of J. C. Kennedy, you say: "We confess that we have heard much of the czar-like action by officers of the Forest Service, but have had poor luck in obtaining facts as to definite actions, etc." Congress by law authorized the President to set aside forest land as forest reserves to protect the watersheds of the streams, and for no other purpose. This is beyond question. The law itself says: "No Forest Reserve shall be established except to preserve and protect the forest within the reservation or to regulate the conduction of water flows and preserve and protect the timber for the use and benefit of citizens of the United States." In defiance of the express provisions of the statute, Mr. Roosevelt, at the request of Mr. Pinchot, set aside as forest reserves, sagebrush deserts in Arizona and New Mexico, treeless table lands in Colorado and Wyoming, and mud flats in Alaska. This non-forest land made into forest reserves in violation of law is in extent double the area of all the New England states and when objection is made, the only reply is to point out the good that the Forest

Service is doing, as if Congress had given the Forest Service a roving commission to go about doing good. The Forest Service has almost entire control of the livestock industry and collects by illegal charges for grazing fees a million dollars a year for which there is absolutely no warrant in law. It attempts to control mining and prospecting by its illegal claim to make expert examination of mining claims. Read the law authorizing the creation of forest reserves and see if there can be found one word that authorizes the forester to employ mining experts. The Forest Service attempts to control water-power sites, although these water-power sites are always in the valleys while the forest reserves, if located as Congress intended, would always be on the watersheds. How is it possible to speak with respect of the action of a man who made a forest reserve out of the mudflats on the shores of Controller bay in Alaska, flats that are covered by the tidewater every day? The Forest Service has not for one minute tried to carry out the wishes and intentions of Congress, but has used the forest reserve law as a blind under cover of which the forester has attempted to exercise control over the entire public domain. The Secretary of the Interior is the person authorized by law to make regulations for the entry of mining claims on the public domain. This is his duty. It is the duty of the forester to raise trees. It is wrong for a prospector to locate a mining claim that has no valuable mineral. It is a waste of money, but it is a matter that does not concern the forester. Western men should refuse to be led into discussion of the good being done by the Forest Service, but should insist that the forest reserves should be limited to the extent authorized by statute and the forester should be required to confine his activities to raising and preserving the trees.

Salt Lake City, July 8.

Simplification of Gold Ore Treatment

The Editor:

Sir—It seems to me that A. W. Allen's article, 'The Simplification of Gold Ore Treatment,' in the *Mining and Scientific Press* of August 16, has avoided the really essential simplifications responsible for the general abandonment of amalgamation in conjunction with the cyanide process. The advantages of detailed cost data are now too generally recognized, and applied, by competent metallurgists, to warrant the assumption that the practice of cyaniding without amalgamation is only fashionable.

It should scarcely be necessary, at this date, to reiterate the various arguments regarding the evils attending all attempts to cyanide after previously crushing in water, as many millmen have always insisted must be done if results are to be had, on the one hand, and those for maintaining amalgamation while yet crushing in cyanide solution, on the other. All schemes have had satisfactory trials, and the present custom of dispensing with amalgamation has been established through good results.

Since Mr. Allen so frequently implied in his ar-

ticle that the only simplification achieved consists of dispensing with amalgamation, as though it were a trifling step in the metallurgical scheme calling for no important consideration of the mechanical processes involved. It certainly behooves readers of the journal to reconsider all problems he alluded to.

Mechanical Appliances

By far the most important merits of the modern practice accrue from purely mechanical considerations, based upon the relative efficiency, indicated by comparing the cost of operations with recovery, rather than the mere question of recovery, to which Mr. Allen's article seems confined. The really prime factor responsible for the present practice is this: it affords the maximum return for the minimum cost of installation, and operation, in the average-size, plant. Another equally important consideration is that it effectually eliminates a constant source of danger, the stealing of amalgam. The one objection which appears to have outlived all others is that it has deprived its operators of their justly prized screen sample, upon which the original value of the ore, and all subsequent calculations, are based. Indeed, for this reason alone, it has been frequently debated in South Africa whether it might not be wise to resume crushing in water once more for the sake of the accuracy of the head sample obtained from the battery screens. But I doubt whether the exasperating details attending the need of eliminating the water, to preserve the economical bulk of stock solution, etc., will ever be compensated for by this, and the slightly improved recovery to which our attention has just been called.

So far as my own experience of the respective operations, mentioned by Mr. Allen, has extended, and I gladly invite correction, the millman is far more often financially embarrassed by the 'float values' than is the cyanide man by coarse gold. In fact, I think that the ultimate gain in recovery, due to the 'float values' recovered only by crushing in cyanide, has of itself often decided the question in favor of abandoning amalgamation.

Increased Strength of Solution

With regard to the increased strength of cyanide solution made necessary by the presence of the un-amalgamated gold, and its effect upon the subsequent chemical loss of cyanide, I should like to learn of the assay value of such ore and the character of the gold content, capable of resisting the action of the tube-mill to any such extent as that statement would appear to imply. It would, furthermore, appear that this concern ignores the effect of the custom of daily precipitating a large portion of the solution returned to the mill, as well as the frequent changes of solution accomplished throughout the course of treatment. Thus, whereas every one may agree that, given the same system of treatment and filtration, the loss in dissolved gold is strictly proportional to the original value of the solution in the pulp, it by no means follows that said original value need ever be at all high.

It is true that even in good practice only a portion of the gold is precipitated. How ominous it sounds! But instead of regarding the fact that,

say, only 97% of the value of the solution is precipitated, let us consider that the bulk of solution remains practically constant, and that it is constantly being precipitated day after day, such that only 3% of its content is allowed to return for subsequent precipitation. The cumulative effect tends to approach perfection rather than any such loss as has been too hastily implied.

Finally, I should like to ask, what would be the gold content of a solution rendered unstable thereby and consequently liable to premature precipitation, and what observations have been made upon such cases?

JOHN B. STEWART.

New York, September 3.

Symmes Agitator

The Editor:

Sir—In your issue of July 19, under the title of 'The Symmes Agitator,' Whitman Symmes describes a very interesting system of agitation installed at the Mexican mill.

In the year 1908 I worked out this same scheme and installed it at the Peregrina mill of the Guanajuato Development Co., of Guanajuato, Mexico. A 30-ft. flat-bottom tank was fitted with a central hollow steel shaft resting on a steel button in the bottom of the tank and protected with a mercury well. The drive was from the top by means of a worm gear. Wooden arms were bolted to the shaft and supported with stay rods. Four air-lifts were flexibly suspended from each radius of the cross-arm. Air-pipes were fastened with hose connections to each lift, and the air jet placed at the bottom. The arms were revolved at the rate of three-fourths of a revolution per minute. The lifts discharged at the surface of the pulp, not in the middle as shown by Mr. Symmes.

The system was for intermittent agitation and settling, so that it was often necessary to start up after an interval of 72 hours of settling. The agitator worked most successfully.

The tank was fitted to handle very fine sand, as the classification was so bad that the ordinary arm-agitators gave much trouble. The system of classification was improved to such an extent that only one of the tanks was finished. I agree with Mr. Symmes that this is one of the most satisfactory agitators I have ever seen and far superior to any system involving pumps.

P. G. SPILSBURY.

San Mateo, Costa Rica, August 11.

Mineral exports from Bolivia during the past two years were as follows:

Products.	1911.	1912.
Antimony	\$26,615	\$1,994

KALGOORLIE, WESTERN AUSTRALIA

BULLFINCH EQUIPMENT DESCRIBED.—MINE PROSPECTS.—THE IVANHOE AND GEOLOGY OF THE WESTERN SIDE OF THE 'GOLDEN MILE.'—GREAT FINGALL, CHAFFERS, CORINTHIAN NORTH, AND VICTORIOUS MINE DEVELOPMENTS.—JUNE GOLD PRODUCTION.

A visit to the Bullfinch is an eye-opener after the way the mine and its equipment have been decried by interested or ignorant parties. Fred Morgan, the manager, is courtesy itself to all accredited visitors, and shows and explains everything. The buildings for the manager, staff, stores, and offices, etc., are quite up to date. The head-gear is 80 ft. high, and the ore from the mine reaches the Symons gyratory rock-crusher from self-dumping skips, and the crushed product then falls into an ore-bin of 200-ton capacity. Self-feeders then deliver the ore to a Robins elevator which conveys it to a Robins tripper to be fed into the mill-bins of 400-ton capacity. On an elevated platform are two feed tanks with a capacity of 30,000 gal. each, as well as two mechanical thickeners, and two settlers of an equal capacity. The mill consists of 15 stamps, formerly at the Cosmopolitan mine. After leaving the mill the crushed pulp is elevated by a 40-ft. diameter tailing wheel into two Callow classifiers. The overflow goes successively into the mechanical thickeners, settlers, and feed

AGITATION AND FILTRATION PLANT AT THE BULLFINCH MILL. RIDGWAY RECIPROCATING FILTERS AT THE RIGHT. NOTE THE TYPICAL DESERT EUCALYPTUS TREES IN THE BACKGROUND.

tanks, then back to the mill. The coarser particles from the classifiers gravitate into a tube-mill and then pass into a Silverthorn & Adair grinding pan. The overflow then returns to the tailing wheel and again circulates. The thickened pulp from the settlers and mechanical thickeners is pumped to three improved Ridgway vacuum-filters, from which the gold solution is passed on to the zinc-boxes. The residue from the filters is agitated with salt water from the mine, and the waste product is sent to the dump by a double-plunger pump. The floors by the battery-house, precipitating and smelting rooms are concreted, so that all waste water and gold solution gravitate to a sump, and are returned to the mill. To complete the installation, another tube-mill and grinding pan, as well as five stamps are being added, which will raise the capacity to 6000 tons per month. In the engine-room are a 350-hp. engine and generator, the former by James Howden & Co. and the latter by Bruce, Peebles & Co.; an 18-drill Ingersoll-Rand compressor of the latest pattern. The hoisting engine is a 14 by 30-in. first-motion, by Fraser & Chalmers. Steam is supplied by three 250-hp. Babcock & Wilcox boilers with superheaters and economizers complete. The various sections of the plant are operated by 11 motors varying from 15 to 70 hp., all controlled from a switchboard in the engine-room. In fact, the system is practically automatic, and

combines economy with efficiency. The mine is being developed at 100, 210, and 310 ft., and ore reserves already blocked out above 210 ft. are conservatively estimated at 158,000 tons, worth \$12.42 per ton. During the erection of the plant, development was practically suspended, but is now being pushed ahead. Mr. Morgan asserts confidently that he could easily supply a mill double the size with ore. This is easily feasible with stopes ranging from 5 to 60 ft. wide. On examining the rich portion of the lode, from which the original owners recovered \$435,000 from 1776 tons, equal to the large average of \$245 per ton, only four men were to be seen at work there out of an aggregate of 160 miners employed. So far as one can judge from present developments, the mine has a long life ahead of it.

Malcolm Maclaren, who reported on most of the mines controlled by Bewick, Moreing & Co., three years ago, is paying a return visit at present. He has thoroughly examined the Great Fingall at Day Dawn, and the Fenian at Meekatharra, and after thoroughly inspecting the Ivanhoe at Kalgoorlie and Sons of Gwalla at Leonora, he will leave for the eastern states. In the four lower levels of the Ivanhoe the ore-shoot has been impoverished owing to an intrusion of graphite, but Mr. Maclaren assured the directors that the intrusion was probably temporary, and when it disappears the ore would again improve. The main shaft is down 2750 ft., and the next level will be 2870 ft., the deepest point reached in any mine in Western Australia. On Mr. Maclaren's advice, the Ivanhoe company has acquired the Ivanhoe Junction and two adjoining leases on the west and intends spending \$48,000 to explore them at depth. Mr. Maclaren's theory is that the gold in the Ivanhoe and Horse-Shoe was precipitated in a quartz-dolerite intrusion, the western wall of which is just outside the Ivanhoe's western boundary. This intrusion dips west at an angle of 65°, and should be in the Ivanhoe Junction claim at a depth of 3000 ft. Mr. Maclaren is of opinion that a new and large profitable lode will be found there, and he has so impressed the directors that they are prepared to risk the above sum to test his theory. Many geologists have drawn big fees for reporting on the mines of this state, but Mr. Maclaren has offered his advice, and this advice has been followed.

The manager of the Great Fingall expects to have the head-frame and double-drum winch erected at the No. 13 level of the mine ready for work in August, when ore for the mill will be drawn from No. 18 to No. 14 levels. The costs will be high, as the interior shaft is 900 ft. north of the shaft at No. 13 level, and the new shoot pitches still farther north. For instance, at the No. 15, there is no ore south of the shaft, and the ore-shoot only becomes profitable 200 ft. north, and continues profitable to 360 ft. At No. 18 level the ore-shoot is profitable from 100 to 580 ft. north of the shaft. The south drift at this level has been extended 400 ft. in low-grade ore that is only worth from \$1 to \$2 per ton at the most. The ore reserves blocked out in the new ore-shoot total 50,000 tons, worth \$9.60 per ton, but the tonnage can quickly be added to when stoping starts and winzes and raises are driven. The upper levels of the mine are practically depleted, and only a few pillars of ore remain, and the future depends entirely on the new ore-shoot. The mine's record is 1,825,280 tons, returning \$23,313,900, and dividends aggregating \$8,734,300 have been paid.

Shareholders of the Chaffers at Kalgoorlie have agreed to the proposed reconstruction of the Company with an assessment of 36c. per share, 12c. per share having already been called for, and the remaining 24c. will be called upon when required. The net amount available after deducting underwriting commission will be \$235,000. A new sulphide treatment plant is to be installed, capable of treating 6000 tons per month. According to Boyd Aarons, the manager, the total costs, exclusive of depreciation and head office expenses, will be \$5.50 per ton. The ore in sight on December 31, 1911, when this estimate of cost was made, was only 104,000 tons of an extractable value of \$6.15 per ton. Deducting costs at \$5.50, this would leave a profit of \$67,600. As this profit did not warrant a new plant, John Morgan,

manager of the South Kalgurll, was commissioned to examine the mine and advise. He suggested further development and pointed out that, as the ore-shoots of the two leading lodes on the Golden Horse-Shoe, No. 2 and 3, and of the main lode of the Great Boulder, known also as the Horse-Shoe No. 4, were pitching into the Chaffers at depth, sinking was more than justified. Since then the ore-shoot in Chaffers No. 4 lode (Horse-Shoe) has been opened for a length of 300 ft. and carries an extractable value of \$6.24 per ton, over a width of 77 in. At the same level Chaffers No. 3 lode (Horse-Shoe No. 2) has been opened for a distance of 43 ft. and has a recoverable value of \$26 over a width of 64 in. The installment of such a small treatment plant at present seems premature, and it would be far better to wait and see if a much larger plant would not be justified. For instance, during the first half of this year, the Golden Horse-Shoe and Boulder together treated an average of 43,070 tons per month, and the ore-shoots from which the bulk of the ore came are rapidly dipping south into Chaffers ground which extends right across the south end of both mines. The average costs of the Boulder and Horse-Shoe were \$5.96 per ton, and it is therefore unlikely that Mr. Aarons' estimate of \$5.50 per ton, working on such a small scale as he proposes, will leave much to go on, and there is little margin for miscalculations.

The Corinthian North mill has been crushing for months, and the result has been disappointing. The mine was to be equipped with a 20-stamp mill, tube-mill, Ridgway vacuum-filters, and all accessories very much on the same line as the Bullfinch under the same control. The output was to be 6000 tons per month, returning \$5.20 per ton. Costs were estimated by Richard Hamilton, of the Great Boulder, and Fred Morgan, of the Bullfinch, at \$3.60, leaving a net profit of \$1.60 per ton. Owing to scarcity of water, the mill has only run at intervals, and in two months has treated only 6566 tons yielding \$21,700. The residue remains untreated, as the filter-plant is not completed, and is estimated to contain \$34,000. The 5-in. pipe-line from the Government water scheme to supply the Bullfinch traverses the Corinthian leases, but does not convey sufficient water to fully supply both mines, and the Corinthian merely gets any surplus. So much for state-managed enterprises under a Labor Government. [We presume this reflects more on the engineering department than the Labor Government itself.—EDITOR.] It is expected that enough salt water will shortly be available in the main workings to make the mine independent of the Government supply except for holler water.

A month has elapsed since the south cross-cut at No. 5 level of the Victorious at Ora Banda, owned by the Associated Northern Blocks, cut the lode, and G. M. Roberts has no cheering news to offer. Where the cross-cut penetrated the lode the ore-shoot was 72 in. wide and assayed \$26.50 per ton, but on driving both ways on its strike, assays only showed \$4.20 going west and \$1.92 going east. As the ore is hard sulphide rock, this is quite unprofitable. Mr. Roberts is still confident that rich ore will again be picked up, as the four winzes sunk from No. 4 level were in rich ore half way down to No. 5 level. The market apparently has faith in the mine, as the price of shares keeps steady. Even if the rich ore-shoot is found, the mine will never be a high-grade property, as there are already opened nearly 300,000 tons of ore of an assay value of \$5 per ton, and it would require a lot of high-grade ore to mix with it to raise the average \$1 to \$2 per ton.

PLATTEVILLE, WISCONSIN

PRICES AND PRODUCTION.—SHIPMENTS FOR AUGUST.—LABOR SHORTAGE.—NEWS OF DEVELOPMENT.

The month of August proved to be one of the best so far this year in this field. Heavy rains and a wide range in prices up and down on the inferior grades of ore militated against a large production the first half of the month. Good roads, good weather, and stronger prices jumped the production from 60 to 90 cars per week the latter half of the month, and this, except for lead ore shipments, was

heavier than usual. One of the most prominent buyers in the field submitted his report showing average prices prevailing in the field during the month, which was as follows: 30% zinc ore, \$16.50 to \$17.50; 35%, \$19 to \$21; 40%, \$23 to \$26; 45%, \$27 to \$30; 50%, \$35 to \$38; 60%, \$46 to \$49 per ton. On open market production the New Jersey Zinc Co.'s buyers set a terrific pace all the way through the month and secured 80% of the entire open market production. The American Zinc Co., of Hillsboro, Illinois, a subsidiary of the American, Zinc & Lead Smelting Co., which fired its new smelter this spring, entered the field during the month. Spelter prices remained firm, Joplin quotations governing in the Wisconsin field. An average price would be about \$5.70 per hundredweight for the month. On this score another large operator is quoted as making this statement in writing: "Don't look for anything better in prices unless spelter gets stronger. Smelters as a rule were low on stocks, but as soon as they get a supply prices will adjust themselves; \$50 ore should mean about \$6 to \$6.25 spelter; instead of that it is now about \$5.70. What we want is a steady market, \$50 ore, and 6c. spelter."

Deliveries of zinc ore for the month of August were distributed among the following buying concerns as shown: Mineral Point Zinc Co., 150 cars, 5481 tons; Grasselli Chemical Co., 52 cars, 2031 tons; National Separating Co., Cuba, 45 cars, 1823 tons; Empire Roasting Co., Platteville, 30 cars, 1108 tons; American Zinc Co., Hillsboro, Illinois, 18 cars, 657 tons; Illinois Zinc Co., 19 cars, 745 tons; Matthiesen & Hegeler Zinc Co., LaSalle, Illinois, 12 cars, 433 tons; Linden Zinc Co., 6 cars, 180 tons; Joplin Separating Co., 2 cars, 71 tons; and Wisconsin Separating Co., 1 car, 30 tons; a total of 435 cars, 12,559 tons. The shipments to the last five named concerns were all high-grade zinc ore. Shipments of ores out of the field by camps are shown in the table herewith.

Camps.	Zinc, lb.	Lead, lb.	Sulphur, lb.
Benton	4,998,000	126,300	4,152,900
Platteville	4,522,000	65,800
Hazel Green	2,814,000	60,000
Galena	2,404,000	82,000
Livingston	2,352,000
Shullsburg	2,210,000
Cuba	2,030,000	112,100	559,200
Linden	1,824,000	233,770
Harker	880,000
Montfort	320,000	80,000
Mineral Point	258,000
Rewey	164,000
Highland	66,000
Potosi	64,000
Totals	24,906,000	536,200	4,945,870

Gross production of concentrates from mines for the month, 22,570,500 lb.; net deliveries to smelters, 16,037,900 lb. The Mineral Point Zinc Co. shipped 30 cars of high-grade roasted zinc ore, 2,262,500 lb., to DePue, Illinois. Potosi entered the list of producing camps with a car of 56% zinc ore from the Wilson mine, a newly organized mining project. Shipments of carbonate zinc ores out of the northern camps were slow in materializing and the first car went out the last week of the month. Several thousand tons of material is ready to go to furnaces at Mineral Point and shipments will be regular for the remainder of the current year.

Briefly told, the following operations are in progress. At Highland the New Jersey Zinc Co. is rushing work on the remodeling of the Kennedy plant. Jigs are all being rebuilt, new crushers of heavy capacity are being installed, the collar of the main hoisting shaft is set in concrete, and a large engine is being assembled. The East End mine, the property of the Wisconsin Zinc Co., at Platteville, is producing 10 cars of zinc ore per week. The Klar-Piquette mine is storing several thousand tons of ore in bin. The Bull Moose mine at Benton is rushing a 100-ton power and concentrating plant to completion. The shaft will reach

the top of the ore deposits at 165 ft. The Martin shaft by the Vinegar Hill is down 140 ft. with 25 ft. more to sink. Two new mills and power plants will be built by the New Jersey Zinc Co. at the Coker and Sunrise mines. The Lawrence equipment newly built is ready to go into commission at Hazel Green. Zinc ore is being stripped at the Scrabble Creek mine owned by the Cleveland Mining Co. The Mineral Point & Northern Railway Co. has appropriated \$65,000 for road improvement and the replacing of all bridges and culverts with steel and cement. It is rumored the road is about to pass into the ownership of the Chicago, Milwaukee & St. Paul line. Prospecting is at low ebb at all points in the field. Labor is in good demand, the Linden, Highland, and Galena districts being short of men. The famous Black-Jack mine below Galena, now being re-opened by the New Jersey Zinc Co., is waiting for the Inter-State Power Co., of Galena, to bring in current. The core of the deposits here have never been touched.

BUTTE, MONTANA

ACTIVITY IN THE EAST CAMP.—COPPER DEPOSITS IN FLATHEAD COUNTY.—JOHN D. RYAN'S ADDRESS TO THE HELENA COMMERCIAL CLUB.—VALUE OF BUTTE OREBODIES AT DEPTH.—LEACHING ORES.—THE BUTTE & GREAT FALLS MINING CO.—THE ELM ORLU MILL.

Many rumors are afloat to the effect that the Thomas F. Cole interests have enlisted the support of the Guggenheims in some Butte ventures. No positive statement is forthcoming as yet, but it is generally conceded that a lot of mining territory near the East Butte property has been recently bought for interests connected with Mr. Cole. As it is generally conceded that the North Butte Mining Co. is about to issue a block of its treasury stock, it is not improbable that the funds thus derived are intended for the purchase of new ground.

Some time ago the rumor of large copper deposits in an out-of-the-way part of Flathead county was recorded, but the United States Geological Survey's report on the district gently but firmly puts a quietus to the boom. The prompt and fearless report of the Survey cannot be too highly commended, as it protects the public from costly investigation and wild-cat investments. Of course, the sponsors of the district will complain, and that loudly, for the claims they hoped to sell will not be sold, and the companies they hoped to promote will not be promoted. It seems that this Felix Basin country is given to copper booms, this being the fifth or sixth stampede started during the last twenty years.

John D. Ryan recently addressed the Helena Commercial Club. The burden of his speech was an appeal to the people of Montana not to misinterpret the motives of his companies. He admitted that philanthropy was not the prime purpose of the Amalgamated Copper Co. or of the Montana Power Co., but he urged that the activities of these corporations were resulting, and would continue to result, in great benefits to the state. He said that the proposed legislation antagonistic to the power company would merely result in retarding hydro-electric development in the state, with its attendant advantages, by scaring away the capital needed in this development. He invited others to come into the power business also, if they wished, as his company controlled but 25% of the available power. Mr. Ryan pleaded that his companies should be commended rather than enviously condemned. The power company had not only developed hydro-electric power which had not theretofore been utilized, but had created a market for this power by the development of irrigation schemes and utilization in the mines and on the railroads. The necessity for Mr. Ryan's speech reflects significantly on pure democracy as a form of government. After establishing these large and important enterprises in entire conformity with the laws of the land, it is still necessary to protect them from harmful *post facto* laws by appealing whenever possible to the sense of honesty and fair dealing of the community.

Local optimists persist in declaring that the Butte mines are getting richer the deeper they are developed. Now,

Butte has not anything to be ashamed of when it comes to rich orebodies in depth, but such statements as the above are not correct. The Butte mines as a whole are not as rich at 2000 ft. depth as they were at 1000 ft., and no one conversant with them makes any claims to the contrary. Copper glance is copper glance, and contains 79.8% copper, whether it is found on the 200-ft. level or the 3200-ft. level, but to say that there is more copper glance in the deeper levels than there was in the higher sulphide levels is getting beyond the facts. Another fallacy, which is hard to down in Butte, holds that there is a distinct lean zone generally throughout the veins from the 1000-ft. to the 2000-ft. level. This conception is a pure flight of the imagination, probably trumped up to encourage deeper sinking in the several fruitless shafts which have been sunk to depths within those figures. When a company has sunk 1500 ft., without good results, on a prospect, its stockholders should be allowed to rest in peace and not be asked to make the 2000-ft. mark on the mythical assumption that they stopped just too soon in the 'lean zone.'

Metallurgists seem ready to admit that some big things are happening, or are about to happen, in the hydro-metallurgy of copper. The Laist plant at Anaconda is nearly ready for operation, and its results will be keenly watched by metallurgists the world over.

The Butte & Great Falls Mining Co. is one of the newer prospecting companies. It owns ground in the northwest outskirts of the district north of the Butte &

GREAT FALLS SMELTER, MONTANA.

Bacorn property. A shaft has been sunk 200 ft. and some lateral work done. It is now proposed to install an electrically driven air-compressor for drills and a hoist. The shaft will then be deepened another 200 ft. at least.

The Elm Orlu Mining Co. is actively at work erecting its zinc-copper concentrator on the side of Timbered Butte. From this it would seem that the rumored consolidation of Elm Orlu with Butte & Superior has come to naught, and that W. A. Clark intends to mine and mill his own ore. This also means that the litigation over orebodies in the two properties will probably come to a head in the near future. Work both day and night is being pushed on the mill building. It is reported that the Anaconda company has ordered material for a plant capable of treating 10,000 tons of tailing per day. The plant will have a capacity just 30% less than the Washoe smelter.

NEW YORK

CANADIAN NICKEL CORPORATION, ALASKA GOLD MINES, FEDERAL MINING & SMELTING COMPANIES.—CALUMET & ARIZONA PROPERTIES.—GOLD HILL CONSOLIDATED.

It appears that the announcement, with much detail, of the organization of the Canadian Nickel Corporation, Ltd., was somewhat premature, and the actual floating of the Company has been postponed until money 'flows' easier than it does just at present. Many important people, including J. R. Booth, F. S. Pearson, J. F. Taylor, and B. B. Lawrence, are said to be interested in the venture. The exploratory work has blocked out a good deal of nickel-copper ore, and the venture will be an important one, once it gets fully started. The shares of the Alaska Gold Mines Co. have been listed on the New York Stock Exchange and trading is active. Reports from the property state that the ore on No. 10 level is giving assays much above expectations; in some places \$3 ore being found. Construction work is being hurried in order to get it completed, if possible, before winter. In its report to the Stock Exchange on July 15, the Company showed a total of \$7,505,816 in assets, of which \$2,750,000 consisted of cash in the bank. When the Company begins work at full capacity, it should considerably increase the gold output of Alaska, which was \$17,198,600 last year. The Yukon Gold Co. was incorporated in California in order to comply with the law of that state before beginning to work its new holdings along the American river. In the Curb market it has been stated that the California holdings would greatly improve the position of Yukon Gold, for its Alaskan properties can only be worked in the summer months, while work in California can proceed all year.

The publication of the earnings of the Federal Mining & Smelting Co. for eleven months of its fiscal year has inspired a fresh circular from Sydney Norman, representative of the minority stockholders, who alleges that if the Federal had received market prices for its metals from the American Smelting & Refining Co.'s smelters the net profit would have been increased nearly \$650,000, or almost doubled. By charging the Federal \$8 per ton for smelting and paying it \$4 less, on its long-time contract, than is paid in the open market for ores of that grade, it is charged that the smelting company obtains two-thirds of the profit and leaves only one-third for the mining company. As the smelting company controls the mining company, it is the minority stockholders who are doing the worrying. In speaking of the A. S. & R., it is interesting to note that the investigators of the United States Department of Justice who have been scrutinizing its record in Colorado are having poor success in eliciting damaging testimony, the general statement being that the Company is fair in its dealings with the mines; complaints usually being based on misunderstanding.

The report that Thomas F. Cole, James Hoatson, Charles Briggs, and Peter Ruppe have been visiting Ajo, Arizona, recently, where the Calumet & Arizona has the New Cornelia and other claims under an option which expires in October, naturally inspires much interest in the possibility of that property and what will be done with it. It is stated that 29,000,000 tons of ore averaging over 1.75% copper has been developed. Surveys for an extension of the El Paso & Southwestern railroad to the property have been begun. The problem of ore treatment is still unsolved, so far as any public statement is concerned, but a staff of investigators, under the direction of L. D. Ricketts, has long been at work upon it, and confidence is expressed that it will be satisfactorily solved.

The Cananea Consolidated Copper Co. is making a good recovery from the disturbed state in which it has been for months past. Its August production is given as 3,186,000 lb. copper, 119,522 oz. silver, and 620 oz. gold. The Braden turned out 1,572,000 lb. copper in August, the rate of recovery at the old mill being 68% of the copper content, and 62.18% at the new.

With the present interest in Appalachian gold mining, the Gold Hill Consolidated has revived under the electric

touch of Walter George Newman, this time as a gold mine. The property, which is in Rowan and Stanley counties, North Carolina, near the Yadkin river, was first promoted more than a dozen years ago by Newman as the Gold Hill Copper Co. It was not long before the property was in the hands of a receiver, and the Gold Hill Consolidated, which bought the property at auction, has never amounted to anything, work being much more active on the Curb than at the mine. Enough work is now in progress to give a color of activity to the property, and more doings on the Curb are doubtless planned. The property has been worked, off and on, for many years, and has produced quite a little gold in the aggregate. Newman is best known for his manipulation of Union Copper, another Rowan county mine, which also has some promise; if worked by miners rather than stock-jobbers.

BOSTON

LAKE COPPER CO.'S AFFAIRS.—CALUMET & ARIZONA.—MEXICAN METALS COMPANY.

On September 9 the Lake Copper Co.'s assessment of \$2 per share was paid, and after that date the stock will be '\$5 per share paid in.' Since the announcement of the assessment on August 18 the stock has held around 6½ per share as compared with its low point this year of 5¼. Apparently, from a market standpoint, the stock is being made to look good until the payment of the assessment. The Company was organized November 28, 1905, and has an estate of 820 acres and was originally the old Belt mine, owned by the Belt Mines Co., Ltd. It is situated about a mile south of the station of Belt, on the Copper Range railroad, in Bohemia township, Ontonagon county, Mich. The Lake lode has been the Company's big asset and in the beginning was shown by drilling to be rich, and the showing caused excitement in Boston. Then came the sinking of the shaft and extensive underground development. After a number of shipments had been made and the property had been opened, it was found by the course of the most northerly drifts that the lode was altering its course, and had changed to the west. It became impossible to correlate it with any of the neighboring lodes, such as the Evergreen, Knowlton, and Butler. J. R. Finlay, three years ago, in his celebrated appraisal work, had no high opinion of Lake. He said then: "It is not by any means assured that this mine will ever pay a dividend." Also: "It is hoped that this mine will prove to be something like the Baltic, in which case about 2,000,000 tons may be conceded to be opened up, which might yield about 40,000,000 lb. of copper. Conceding that this product may be obtained at a profit of one cent per pound during the next ten years, we get a present value of about \$300,000 for this property." The Lake company has 100,000 shares outstanding, which, after September 9, will represent \$5 per share paid in. But over a million dollars has been spent on the property, as the Company's treasury has realized as high as \$33 per share for the stock from underwriters and 6500 shares was disposed of by the former management in the open market at from par, \$25, to \$71 per share.

Calumet & Arizona is a company which is being managed with great foresight. Nearly five years ago the management began a policy of acquisition of various outside properties and the laying aside, out of earnings, of a fund for the purchase of properties in Arizona and New Mexico. The Irish Mag orebody of Calumet & Arizona has produced a large quantity of ore.

The directors of the Mexican Metals Co. have called an assessment of 15c. per share. The Company is operating in Sonora and makes a statement showing that from June 1911 to July 1913 it made a loss of \$2400, the deficit being due, according to the management, to the continued interference with operations on account of the chronic warfare around the mines. Some of the strongest interests in New England are understood to be behind the Company and are said to be desirous of making it an operating success.

General Mining News

ARIZONA

GILA COUNTY

The London-Arizona Consolidated Copper Co. has been organized under the laws of Maine with a capitalization of 2,400,000 shares, par value \$5 each, or a total of \$12,000,000. This new organization was promoted for the purpose of acquiring and taking over the properties of the London-Arizona Copper Co., London Range Copper Co., London Shamrock Copper Co., and Bail Copper Co. The consolidated property comprises 2357 acres of highly mineralized and developed copper ground situated about five miles north of Winkelman, and four miles from the new smelting plant of the American Smelting & Refining Co. at Hayden. The holdings of the consolidated company comprise the heart of the lime-porphyry deposits. The directors of the Company are Volney D. Williamson, Walter A. Burrell, John A. Finch, Robert Sweeny, B. F. Cheney, J. H. Neff, Richard E. Sloan, Frank M. Murphy, and Charles E. Finney. The consulting engineer and geologist of the London-Arizona Consolidated will be Edward W. Brooks, of Los Angeles, and the engineer in charge of operations of the properties will be Henry Kehoe.

GREENLEE COUNTY

The Arizona Copper Co., at Clifton, will add a number of motors to its electrical equipment, including two 10-hp., two 50-hp., four 75-hp., and two 100-hp. motors with compensators and switches, all of which have been ordered from the General Electric Company.

CALIFORNIA

AMADOR COUNTY

At Jackson, the suit between the Kennedy Extension Mining Co. and the Argonaut Mining Co. is now being heard. The complaint alleges that the Argonaut company, for three years prior to April 6, 1910, had wilfully mined and extracted ore from plaintiff's ground, and particularly from the 2760, 2880, 3000, 3150, and 3300-ft. levels, to the extent of 50,000 tons, valued at \$500,000, and ore is now being extracted at the rate of 5000 tons per month. In its answer, the Argonaut company admits working under ground of the plaintiff, but always on its own vein, and makes a general denial of the principal allegations. It admits driving parts of the 1460 and 1690-ft. levels beyond the southern boundary of its property and underneath the surface of the Jackson quartz claim, but that such levels were unproductive. Damages were originally claimed of \$500,000, but have since been increased to approximately \$1,000,000.

CALAVERAS COUNTY

Stockholders of the Lightner Mining Co., nearly all of whom are residents of San Joaquin county, have given an option to the Tonopah Mining Co. of Nevada. The option gives the Tonopah company ninety days' time from September 5 to complete the purchase. The terms of sale are private. The deal also includes the Sultana, Maltman, and Baunager properties.

PLACER COUNTY

The hull of the dredge which the Pacific Gold Dredging Co. is building at Mammoth Bar, on the middle fork of the American river, has been launched, and the machinery is now being installed. It is expected that the dredge will be ready for operation early in October. The work of building the dredge will be done in fast time, as the first load of lumber was hauled to the bar on July 17. The hull is 105 ft. long by 40 ft. wide and 10 ft. 4 in. deep. The total weight of the material used in the construction will be over 700 tons. The buckets will be of 7-cu. ft. capacity, and the Pacific Gas & Electric Co. will supply the power. Lee Davis will be dredgemaster with a crew of twelve men.

SHASTA COUNTY

(Special Correspondence.)—The Accident Gold Mining Co. is arranging for the reopening of the Sybil mine, at

French Gulch. The property has been idle fifteen years, resulting from litigation, but a compromise between the warring factions was recently effected. E. C. Percival is manager. The shaft of the Gladstone mine, French Gulch, will be sunk deeper as soon as present repairs are completed. The present depth is 1100 ft., and the shaft is sunk from the end of a 4000-ft. adit. J. Deisthorst is planning the installation of a device to treat the black sand on his placer claims on Clear creek, just below Redding. The sand has been sluiced to dumps in the past, but a recent assay showed a good gold content. Oroville people have interested Mr. Deisthorst in a new process. A. J. Field and associates are installing a refrigerating plant at their small experimental smelter in this city. The plant is designed to treat sulphurous ores without generation of noxious fumes. The Field process, based on refrigeration, will be employed. It is expected to make initial tests before the end of the fall. Tests of the Hall desulphurizing process at the Balaklala smelter have been delayed by mechanical troubles, but these have been adjusted. The California, Shasta & Eastern company has acquired the Terry railroad, from Anderson to Bella Vista, and it is stated the extension to Ingot and the Afterthought copper mine will be commenced as soon as material can be assembled. It is further reported that the change in ownership of the railroad will result in heavier ore shipments from the Donkey and other zinc-copper mines in the Ingot district.

Redding, September 8.

TRINITY COUNTY

(Special Correspondence.)—The East Fork mining district in this county is improving slowly but surely. With the extension of good trails beyond the wagon-road, which is being done jointly by the county and the United States

Forestry Service, all parts of the district are easy of access. Another improvement made by the Forestry Service is a telephone line through the district. These aids to opening the country are much appreciated, as transportation and communication is absolutely essential to the development of all districts. The lease of the Enterprise mine by R. A. Skinner and J. D. Day expired on September 1. Their last clean-up, the result of six weeks' run, was valued at over \$6000. The mine will soon resume operation. D. G. Reed, of Redding, will soon begin work on the Ozark, which has produced high-grade ore. Mr. Skinner will soon begin development on the Yellow Stone, which has been closed for some time, but has a fair record. Mr.

Day is developing the Fritz. The Yellow Aster and Yellow Jacket are temporarily closed. A. A. Wolfe and Chas. Meyer, who own the Oversight and Old Oaks, respectively, will continue development through the winter. L. J. Johnston, owner of the Bonanza group; Wm. McLaren, owner of the Trinity group; and T. J. Rochfordetl, of the Golden Chest group, are all busy and expect to carry on development during the winter. All of these properties are opening well, considering the amount of development which is being done, and they all have some high-grade ore. There are free gold, high-grade galena, and telluride ores here. Some high-grade sylvanite ore was mined from the Yellow Aster, and some petzite was also identified.

Placer mining in this district will soon be only a matter of history. Andy Williamson, of Rich Gulch, is busy preparing for his winter run. Merkel and Morgan, who have taken over the old Watrous mine, are also getting ready for winter, while the Poso Rico's owners, W. S. G. and G. M. Todd, have just finished cleaning-up from a successful run. These properties are operated by hydraulicking, and coarse gold is recovered. Some ground has returned as high as 80c. per cubic yard. This strengthens the opinion that the quartz mines will in time make good.

Helena, September 5.

TUOLUMNE COUNTY

(Special Correspondence.)—At the Moccasin Consolidated Mines, about eight miles south of Jacksonville, a new duplex, enclosed-frame, Corliss type, electrically driven compressor is being installed. Considerable development work is in progress, and a new 20-stamp mill is contemplated this fall. W. G. Anderson, recently of Nevada, is superintendent.

Jacksonville, September 13.

(Special Correspondence.)—The Curtis Bros. Mining & Milling Co., consisting of W. Walter Curtis and J. Francis Curtis, formerly of Angels Camp, have taken an option on the Wickham mine, near Jamestown, and will sink a 100-ft. winze. The mine is fully equipped with a 5-stamp mill, and it will not be long before some good ore will be milled. Curtis brothers are sons of the late Joseph F. Curtis, for years one of the best known of the old-time Mother Lode miners, having operated and promoted mines for more than thirty-five years in Calaveras county. Among some of the mines promoted were the Royal Consolidated mines at Hodson, and the Waterman gold mine at Angels Camp. He was about to make a deal for the Tulloch mine at Angels Camp when he died.

Jamestown, September 6.

COLORADO

CLEAR CREEK COUNTY

A number of stockholders of the American Rotary Tunneling Machine Co. were at Georgetown last week to see the machine work. Everything at the American adit is now in good order, and the machine cuts nearly 6 inches in hard granite per hour, boring a hole 8 ft. in diameter. Water is plentiful, as the new pumps supply it from the reservoir of the American Sisters Power Co., and the machine has been improved so that it now requires only about half the amount of water previously needed. James Garrett & Co., lessees at the Seven-Thirty mine, are stopping a 12-in. vein for a length of 80 ft. A shipment of first and second-class ores returned 170 oz. silver and 48% lead, and 54 oz. silver and 15% lead, respectively. Herber and Hanson have a fine lease at the Waldorf property, and are stopping \$45 and \$65 ore. The main raise between the Capital adit and the 300-ft. level has been completed. The raise extends 175 ft. above the 300-ft. level, and is being driven as rapidly as possible.

GILPIN COUNTY

The Carr Mines Co., of Central City, will install two 50-kva. transformers, a 75-hp. motor, and accessories recently purchased from the General Electric Company.

SAN JUAN COUNTY

Following are the shipments of concentrate and crude

ore from the Silverton district during August: Concentrate: Gold Hill, 1000 tons; Sunnyside, 600; Iowa Tiger, 575; Barstow, 380; Silver Ledge mill (Warner), 110; Frisco Tunnel, 100; and Intersection, 20 tons; a total of 2755 tons. Crude ore: Southern Exploration & Mining Co., 360 tons; Dives, 300; Gold Tunnel, 150; Arastra Leasing Co., 150; Allerton, 130; Ed. Fiant, 80; Vanderbilt, 40; Celtic Leasing Co., 40; Miller & Shaw, 20; Taylor & Anderson, 20; Mayflower, 20; E. Zanoni, 20; Aspen, 20; and Frank Hough, 20; a total of 1390 tons.

TELLER COUNTY (CRIPPLE CREEK)

The Victor mine, on the northeastern slope of Bull cliff, owned by the Victor Mining Co. and operated under lease by A. Osberg, in August made a production of 26 cars, or between 650 and 700 tons of ore, with an average value of \$20 per ton. Seven sub-lessees are working under the Osberg lease, and extensive development of the property is under way. The Vindicator Con. Gold Mining Co. employs from 110 to 125 men on company account, and there are from 75 to 100 employed by lessees. Thirty sets of lessees are actively engaged on the Battle mountain properties of the Granite Gold Mining Co., and the production made in August totaled 65 cars or approximately 2000 tons.

IDAHO

CUSTER COUNTY

The smelter at the Lost Packer mine was in operation for 24.6 days and 1800 tons of ore was treated, producing 380 tons of gold and silver-bearing copper matte. This matte is now being sold at Salt Lake City, five cars having been received up to the present time. The matte averages from 8 to 10 oz. gold, 26 oz. silver, and 45% copper. A small force of miners is now at work on development in preparation for next season's smelting operations. The Lost Packer property is owned by prominent Salt Lake City capitalists who, every season, operate the smelter despite the innumerable difficulties that stand in the way of successful production. The mine and smelter are situated high in the mountains, 113 miles distant from a railroad, with a trail that is difficult to follow. The short smelting season is a disadvantage also, while during the season just ended, the Company used 300 horses for bringing in supplies and fuel and for taking out the smelter product. During the season 80 men were employed at the mine and smelter. Fortunately, however, the ores of the Lost Packer company are high grade, and, despite the difficulties, the Company will pay a dividend.

IDAHO COUNTY

(Special Correspondence.)—At the Mt. Marshall mine, in the Marshall Lake district, the company is driving a cross-cut adit 2000 ft. long to cut two gold and silver quartz veins at 800-ft. depth.

Resort, September 3.

SIOUX COUNTY

The Monitor Mining Co., which operates the Monitor mine, near the Montana line, in the Mullan district in Idaho, is planning to drive a long lower adit to cut the orebodies at approximately 2000 ft. vertical depth and provide facilities for developing other properties adjoining. The Monitor in the last few years has shipped a number of cars of high-grade copper ore, containing gold, and the Richmond and St. Lawrence properties, situated on a parallel vein and adjoining the Monitor, have excellent showings of high-grade copper. The Bunker Hill & Sullivan Mining & Concentrating Co. bought the \$30,000 issue of the Kellogg sewer bonds on September 10. The Nabob Mining Co. will take over the Idaho and 'V' group of claims adjoining. Both properties are opening in a satisfactory way.

MICHIGAN

HOUGHTON COUNTY

(Special Correspondence.)—The strike in the copper district is gradually wearing out, and as the miners return to work the strikers are leaving. The Calumet & Hecla daily 'rock' shipments average 3500 tons, and the Copper Range properties 1000 tons. At the former mine there is

a trammers' strike, and the miners are doing their own tramping. Western Federation officials are differing in opinion regarding the general strike. Clarence Darrow has been visiting with the president, C. H. Moyer. Strike pay is coming in freely, and the men who stick to the Federation will probably have plenty of food for some time. James McNaughton, manager of the Calumet & Hecla, has interviewed the governor of the state of Michigan. The women relatives of strikers have shown a despicable attitude to non-strikers.

Houghton, September 11.

The Calumet & Hecla Mining Co. will install new electrical apparatus consisting of seven motors ranging from 15 hp. to 1250 hp., a 7-kw. turbo-generator set, an 8-kw. generator, one 7½-kva. and three 15-kva. transformers, switchboard, and accessories. This equipment has been purchased from the General Electric Company.

MISSOURI

JASPER COUNTY

Extensive work in the local district is planned by the American Zinc, Lead & Smelting Co. Already two mills that were idle for several months have resumed operation and the Company intends to move both the Vogey mill at Porto Rico and the American Davey No. 1, at Prosperity, to new leases which are now under course of development. There have been rumors that this Company was to reduce its operations in the district, but this is not so. With three large mills now in operation at Prosperity, the Company is reported to be in shape to treat more than 500,000 lb. of zinc sulphide ores per week and more than 100,000 lb. of galena. When the No. 1 mill is removed to its new situation, the production from the Company alone will amount to nearly 800,000 lb. of zincblende concentrate and about 200,000 lb. of galena per week.

Ore shipments from the Missouri-Kansas-Oklahoma district for the first eight months of the year were: zinc, 180,243 short tons, valued at \$7,887,340; lead, 30,424 tons, worth \$1,642,591; and 'silicate,' 11,830 tons, worth \$362,834.

MONTANA

BROADWATER COUNTY

There are reports of steady progress and a promising outlook from the Ohio-Keating property, which lies in the Radersburg district, about 1½ miles from that old mining camp. The shaft of the Ohio-Keating is now down 500 ft., and driving has been done on all levels in both directions. The veins are from 2 to 5 ft. wide and average \$30 per ton in gold, the ore being a heavy sulphide. The equipment for this property is among the best in the state. It has electrically equipped compressed-air hoist and pumps. There is one triplex vertical pump on the 300-ft. and another on the 500-ft. level. During August, 20 carloads of ore were sent to the Washoe smelter.

FERGUS COUNTY

During August the Barnes-King Development Co. treated 4310 tons of ore, yielding \$32,088. The profit was \$17,003, of which 75% goes to the North Moccasin interests as part payment for the property, on which \$29,091 is still payable.

SILVERBOW COUNTY

The Butte & Superior mill treated 30,440 tons of ore in August, producing 11,300 tons of concentrate assaying 49.41% zinc, with a recovery of 90.9 per cent.

NEVADA

CHURCHILL COUNTY

During August the Nevada Hills, at Fairview, treated 4368 tons of ore containing \$78,150, the net realization being about \$40,000.

ESMERALDA COUNTY

On September 13 an electric storm accompanied by heavy rain did great damage to life and property at Goldfield, but all is again in working order. On the 500-ft. level of the Booth a large body of quartz has been cut. The Florence mine is shipping 50 tons of \$20 ore per

day to the Bonnie Claire mill. The mine is opening satisfactorily.

LINCOLN COUNTY

According to H. W. Rand, in an interview with the *Salt Lake Tribune*, the Pioche district is more active than for years past, and there is developed between 300,000 and 400,000 tons of ore averaging about 35% iron, 3 oz. silver, and 3% lead. The Prince Consolidated has produced similar ore for some time past. The Virginia-Louise adjoins this property and has been opened to the 460-ft. level. The Amalgamated Pioche is doing a good deal of mine work and installing new equipment.

LYON COUNTY

(Special Correspondence.)—W. E. Greenawalt reports to the Nevada-Douglas Copper Co. from Denver that he is rapidly getting the experimental plant in shape for operation and that he will be ready to start testing the ore as soon as the motor-generator sets arrive from the factory. These are due to arrive at an early date. He also reports that he is making good headway with the plans for the first 100-ton unit of the plant to be erected at the mine. As soon as these plans are completed, it is hoped to start construction work without delay.

Yerington, September 6.

NYE COUNTY

Tonopah mines produced 11,484 tons of ore worth \$272,190 during the week ended September 13. August returns were as follows:

	Tons.	Value.	Profit.
Belmont	15,482	\$315,142	\$184,994
Tonopah	14,475	220,100	119,100
West End	4,115	57,044
Merger	22,000	11,000

WHITE PINE COUNTY

It is probable that the Consolidated Copper Mines Co.

ELY, NEVADA.

will erect a reduction plant at Warm Springs of 5000 tons daily capacity. This is three miles from Ely, and as the works would be of great benefit to the town, the manager, E. F. Gray, has asked residents to sign a document releasing the Company from all damages that might accrue from smoke and dust from the plant.

A No. 5½ Keystone Missouri drill is being set up at the Argus property at Taylor, which contains lead-silver ores.

SOUTH DAKOTA

LAWRENCE COUNTY

(Special Correspondence.)—At the Trojan mill construction work on the additions to house the tube-mill, solution-storage tanks, thickeners, and agitators, is proceeding rapidly, and a Lea recorder has been installed.

A Bury two-stage compressor, with air cylinders 14 by 7½ by 10 in., driven by belt from a 50-hp. motor, has just been installed at the Bismarck. Additional drills will be used in the mine. The ore is broken in a large open-cut, dropped through chutes, and trammed to the mill. Some expensive stripping is necessary at present. The operations in July showed a good profit.

A small steam locomotive has been put in operation to draw the cars of waste which are loaded by the steam-shovel in the course of stripping at the Wasp No. 2 mine.

In making adjustments of valuation for purposes of taxation, the recently created State Tax Commission has raised the Homestake Mining Co.'s assessment from \$8,000,000, as returned by the county commissioners, to \$16,000,000. Many people regard this as an unjust valuation, and it is believed the Homestake company will make an effort through the courts to have it reduced.

Deadwood, September 6.

TENNESSEE

A meeting of geologists, mining engineers, and others interested in the development and conservation of the mineral resources of the country was held at Knoxville under the auspices of the National Conservation Exposition, on September 19. This meeting was held in conjunction with the miners' field day on Saturday.

UTAH

JUAB COUNTY

From the 700-ft. level of the Eagle & Blue Bell mine at Tintic, a car of ore has returned 75% lead, 25 oz. silver, and a little gold, the smelter giving \$4750.

SUMMIT COUNTY

During the month of August, 160 cars of ore, aggregating 6453 tons, was shipped from Park City. The amount shipped by each company was as follows: Silver King Coalition, 3216 tons; Daly-Judge, 1393; Daly West, 1106; American Exploration Co., 141; Grasselli Zinc Co., 149; Ontario Silver Mining Co., 111; Mines Operating Co., 67; Thompson-Quincy, 37; 'creek jiggers,' 62; and E. J. Beggs, 46 tons.

UTAH COUNTY

Although little news comes from the American Fork district, yet it is reported to be quite busy. Lessees at the Pacific are stoping 18 in. of galena 300 ft. from the portal of the main adit. At the Dutchman property there is 2 ft. of rich silver-lead ore being mined, while both the Silver Flat and Miller Hill mines are opening encouragingly.

CANADA

BRITISH COLUMBIA

The Hedley Gold Mining Co. will pay on September 30 a quarterly dividend of 3% and an additional one of 2 per cent.

Construction work on the Grand Trunk Pacific railroad in the northern part of the province may be delayed on account of the rush to the new gold placer district at Sibola creek, 110 miles southwest of Telkwa, on the Grand Trunk line.

ONTARIO

The Hollinger Gold Mines Co. paid a dividend amounting to \$90,000 on September 9, making a total of \$1,080,000. During the month ended August 12 the mill treated 11,654 tons of ore valued at \$18.37 per ton, with an extraction of 97%, at a cost of \$1.38 per ton. The profit amounted to \$141,733, and surplus after paying dividends \$625,202. The most important result of the four weeks' work has been the cutting of No. 1 vein on the 425-ft. level. The vein shows a width of 10 ft. and was reached at a distance of 26 ft. from the bottom of the winze. The ore is similar to that on the upper levels and assays average \$18 per ton.

COLOMBIA

The Pato dredge of the Oroville Dredging Co. returned \$3300 from 17,300 cu. yd. during the week ended August 19. The dredge is still employed in digging toward the 310 acres of tested ground.

MEXICO

JALISCO

During August, El Favor mill yielded bullion worth \$43,000, to which has to be added smelter returns from ore and concentrate shipped from El Favor and Mololoa mines. Fourteen cars of machinery for the mill of the Cinco Minas Co., in the Hostotipaquillo district, is on its way to the mine. The manager, H. E. Crawford, hopes to have the mill completed and in operation by the first of next year.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

CHARLES BUTTERS is in London.

C. S. HALEY left for Colombia Friday.

F. F. SHARPLESS is at Golconda, Nevada.

RICHARD BECK was in New York last week.

PIERRE BOUREY was in San Francisco this week.

H. V. WINCHELL was at Butte and is in California.

RALPH ARNOLD has been at Lake Tahoe for the week.

J. F. THORN will be in New York the last of the month.

HOWARD D. SMITH is expected in the Santa Maria oil-fields.

CHARLES E. VAN BARNEVELD returned from the East Tuesday.

F. LOEWINSON-LESSING has been visiting California dredging fields.

A. DICKEMAN has left Idaho and gone to Barranquilla, Colombia.

J. C. JONES is in a hospital at Reno, as a result of football injuries.

S. S. SORESEN sailed for England on September 10, and will proceed to Chile from there.

POPE YEATMAN has left New York for Chile, where he will be joined by Walter Broadbridge from London.

R. B. LAMB, who has been at Austin, Nevada, recently, passed through San Francisco and Los Angeles this week.

G. A. PACKARD gave a talk on the Cooke City district at a recent meeting of the Montana Society of Engineers, at Butte.

DESAIX B. MYERS will be in Nevada county, California, this week, and at Eldorado Canyon, Nevada, the first week in October.

JOHN D. RYAN, president of the Amalgamated Copper Co., delivered an address before the Helena Commercial Club on September 12.

J. C. BRANNER, president of Stanford University, has been decorated by the Brazilian Historical and Geographical Institute in recognition of his many contributions to Brazilian history and geology.

The San Francisco Section of the Mining and Metallurgical Society held its first dinner of the fall at Hotel Oakland Tuesday last. Those present were S. B. CHRISTY, R. E. CRANSTON, C. W. MERRILL, E. B. KIMBALL, P. R. BRADLEY, E. L. OLIVER, F. L. RANSOME, A. C. LAWSON, and H. F. BAIN.

Obituary

JENNINGS STOCKTON COX, JR., died at his home, 140 West Seventy-first street, New York City, on August 30. He was graduated from the School of Mines of Columbia University in 1887 and began work with the Carnegie Steel Co. of Pittsburgh, as draftsman in the Homestead works. In 1890 he served as inspector of construction in Roach's shipyard, Chester, Pennsylvania, and spent the following year in professional work in Brazil. During 1892 he was assistant superintendent of the Aurora Iron Mining Co., Ironwood, Michigan, and the next year held a similar position with the Monte Cristo and other mining companies in Washington. After spending some months in professional work in New York and Cuba he became agent for the Crocker-Wheeler Electric Co. at Pittsburgh. Going to Cuba in 1897 he became general manager for the Spanish American Iron Co., at Santiago, Cuba, which position he held until the time of his death. He was very prominent in the industrial development of Cuba; among other activities, being secretary and treasurer of the Pompo Manganese Co. Ten years ago he married Miss Ysabel Ramsden, the daughter of the British Consul at Santiago. He returned from Cuba three months ago on account of his health. He was a member of the University Club, the Alpha Delta Phi fraternity, and of the American Institute of Mining Engineers.

The Metal Markets

LOCAL METAL PRICES			
San Francisco, September 18.			
Antimony.....	12-12½c	Quicksilver (flask).....	\$39 50
Electrolytic Copper.....	17½-17½c	Tin.....	46-47½c
Pig Lead.....	5.00-5.95c	Spelter.....	7½-7½c
Zinc dust, 1400 lb. casks, per 100 lb., small lots \$9.50-9.75; large \$7.50-8.50			

EASTERN METAL MARKETS
(By wire from New York.)

NEW YORK, September 17.—The copper market is strong and advancing; early copper is scarce and the consumers are poorly supplied. Electrolytic is quoted at 16.87 to 17c., Lake 17c., and casting from 16.62 to 16.75c. The London market is reported quiet, with spot copper at £74 12s. 6d. and futures at £74 7s. 6d. Lead is quoted at £20 12s. 6d. Bar silver is quoted at 60½c., and Mexican pesos at 46c. Tin market is easy, with spot at 42.40 and 42.75c. Antimony is dull; Cookson's quotations, 8.30c. The demand for copper is strong at 17c. and a still higher price is predicted.

QUICKSILVER

The primary market for quicksilver is San Francisco, California, being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

TIN

New York prices control in the American market for tin, since the metal is almost entirely imported. San Francisco quotations average about 5c. per lb. higher. Below are given average monthly New York quotations, in cents per pound:

Monthly averages.					
	1912.	1913.		1912.	1913.
Jan.	42.53	50.45	July	44.25	40.70

June	45.76	45.10	Dec.	49.80

Anything more uninteresting than the tin market during the week ended August 23 could hardly be imagined, according to Henry R. Merton & Co. Speculation in the metal is absolutely dormant, and even the professional element is disinclined to show its hands. There was some enquiry for metal from American as well as from Continental consumers, which kept the market generally firm, but whenever the demand was satisfied, prices fell back from sheer inaction. Prices for spot metal ruled high at times, touching £189 15s. early in the week, but the premium fell off when holders were tempted to lend some good lines. Transactions during the week amounted to about 152½ tons.

COPPER			
Quotations on copper as published in this column represent average wholesale transactions on the New York market and refer to electrolytic copper. Lake copper commands normally from 1-5 to 1-4c. per lb. more. Prices are in cents per pound.

With the announcement by the Copper Producers' Association, on September 8, that copper stocks had declined to 38,300,000 lb., or 6,000,000 lb. below the previous low record, corresponding to only eight days' supply of the metal, the price of copper was marked up to 16½c. per pound. Buying was fair at first, but soon fell off with the news of a drop of over £1 per ton of standard copper in London, H. R. Merton & Co. being heavy sellers on speculative accounts. Throughout the week sales remained light, though producers held their demands firm. It is obvious that all domestic buying has been on a 'hand to mouth' basis, and indicates that consumers are of the belief that with the capacity of the mines increasing at a steady rate and general business rather slack, there can exist no sound basis for any permanent advance in copper prices. Not a few persons are frankly skeptical in regard to European statistics. For months exports to Europe have been far above normal, and for the first eleven days of September were 12,335 tons, as compared with 11,020 tons in the same period of last year. Trade conditions in Europe have not averaged better than in this country, and in Germany there has been a general movement to put trade on a less extended basis than has resulted from the efforts to push German trade in foreign countries during the past decade. That under these circumstances Europe can continue to absorb unprecedented amounts of copper in the natural course of business is at least open to doubt, and not a few well informed people intimate that visible stocks are being converted into invisible ones for the benefit of the market. The Amalgamated continues to buy warrants on the London Exchange, and is said to plan shipping 'blister' to this country for refining. It has been suggested that this is really to provide 'standard' copper for trading on the New York Metal Exchange, where an attempt has been made to build up trading in copper warrants, as in London. The real traders in copper in New York ignore the Exchange's existence, and it should not require many tons of standard copper to meet all its needs. Some of the producers talk seriously of a 'runaway' market, but for the time being it is decidedly easy-going.

THE PAST WEEK AT COBALT

The Buffalo Mines Co. will pay a dividend and bonus amounting to \$200,000 on October 1, and \$70,000 on November 15, making the total to date of \$2,527,000. During August the Nipissing high and low-grade mills treated 171 and 7824 tons of ore, respectively, while the refinery shipped 553,698 oz. of silver bullion. Most of the yield came from No. 73, 80, and 63 shafts. Diamond-drilling is being done near the old Nova Scotia property in diabase. Hydraulic prospecting uncovered several small veins. On the 200-ft. level of the Cochrane an irregular vein is being opened. Steamship companies carrying Cobalt bullion to England have raised their rates from \$4.50 to \$7 per 100 lb., so the bullion will now go to New York.

GOLD AND SILVER PRODUCTION OF THE UNITED STATES.

The production of gold in the United States during 1912 amounted to \$93,451,000, a decrease of \$3,438,500 as compared with the previous year, and the lowest production since 1907. The output of silver was 63,766,800 fine ounces, valued at \$39,197,500, an increase of 3,367,400 oz. over 1911, the greatest gain being made in the state of Utah, according to the joint statement of the Mint and the United States Geological Survey. The decrease in gold was caused by a reduction in Nevada's output by \$4,521,200 as compared with 1911. George E. Roberts, Director of the Mint, states that while the output of gold had decreased in the United States and Australia, there was sufficient increase in South Africa to make the world's production of gold for 1912 greater than in 1911. Statistics are not yet available on the world's production.

The production of gold and silver by states during 1912 was as below, and compared with figures in our review of January 4, 1913, there is a difference of about 1.5 per cent.

THE CARNEGIE STEEL Co. is rebuilding one of the open-hearth furnaces at its Sharon works for burning powdered coal. Two other furnaces will also be equipped the same way. Three furnaces are using coal tar as fuel.

Company Reports

STEWART MINING COMPANY

This Company operates in the Coeur d'Alene district, Shoshone county, Idaho, and the report covers the first half of the current year. Results may be summarized as follows:

Ore milled, tons	87,283
Ore shipped to smelters, tons.....	1,963
Metal contents of ore mined:	
Silver, ounces	657,416
Lead, pounds	13,545,300
Revenue from concentrate	\$466,466
Revenue from ore	74,644
<hr/>	
Total	\$541,110
Working expenses	294,249
Litigation	38,791
Profit	208,070
Dividend	123,836

The operating profit and net profit for the period under review are both slightly lower than for the preceding term, but the net earnings during May and June are much higher than the average of the six months. Current assets are \$483,951 and liabilities \$57,084.

Costs at the Stewart mine, Shoshone county, Idaho, during the first half of 1913, were as follows: Mining and development, \$2.28; transport of ore, 15c.; sorting ore, 4c.; milling, 37c.; administration and general expenses, 31c.; taxes, 10c.; depreciation, 5c.; and litigation, 43c.; a total of \$3.73 per ton.

KERR LAKE MINING COMPANY

This Company was incorporated under the laws of New York state in 1905, and owns 395 out of 400 fully paid shares of the Kerr Lake Mining Company of Ontario, Canada, owning silver-mining property in the township of Coleman, Nipissing district, Ontario, Canada. The capital is 600,000 shares at \$5 par value, \$3,000,000. The report for 1912 gives the production of silver by the operating company for the year as 1,855,495 oz. Of this, 1,741,804 oz. was produced from high-grade and 113,691 oz. from milling ore, which was sent to customs mills for treatment. The total cost of production per ounce of silver was 18.3c., made up as follows: mining 12.1c., shipment and treatment 5.55c., and administration and general 0.65c.

This increase over last year's report is principally due to the greater amount of development work per ton of ore mined, and larger proportion of lower-grade product shipped. The greater cost of treatment is due to the increasing proportion of low-grade ore handled. The total estimate of ore reserves September 1, 1912, contained 6,660,091 oz. of silver. The average price the Company received for its silver was 60c. per ounce. The net profits for the year, above all expenses, was \$703,309. The Company paid its stockholders \$690,000 in dividends, a total to date of \$4,020,000. This Company owns 150,000 shares of the Wettlaufer Lorrain, valued at \$60,000, and 200,000 shares of Kerr Lake Majestic Mines, valued at \$79,548. Cash on hand amounts to \$2316 and a reserve of \$1350 for outstanding liabilities is maintained.

THE VILLAGE MAIN REEF GOLD MINING COMPANY

The Company was registered in 1890 to take over the property of a South African company of the same name, comprising 20 main reef deep-level claims on the farm of Turffontein, Witwatersrand district, Transvaal. The capital is £472,000, in 472,000 shares of £1 each; all the shares are issued and fully paid. The report for 1912 shows a total of 563,511 tons mined. The total cost of mining was £286,872. The tonnage treated in the cyanide works was 470,535 tons, yielding 72,023 oz. fine gold. The value of the yield from the mill was £628,715, or £1 6s. 9d. per ton, based on tonnage milled; the value of the yield from the cyanide plant was £301,013, or 12s. 10d. per ton, a total revenue of £929,728, or £1 19s. 7d. per ton. This is an

increase of about 2s. 3d. per ton compared with 1911. The total working cost was £437,513, or 18s. 7d. per ton, an increase of 6.9d. per ton compared with 1911. This gives a working profit of £492,215, or £1 0s. 11d. per ton. In addition, a profit of £8911 was obtained from the treatment of 28,633 tons of 'accumulations.' The ore reserves were estimated at 1,683,066 tons, with a gold content of 33s. 7d. per ton. The realized net profits for the year were £443,176. Two dividends were paid during the year, each of 7s. per share, amounting to £330,400. The cost of mining, including delivery of the ore to crusher station, was 10s. 4d. per ton. Results were as follows:

Ore from mine, tons	563,511
Sorted out as waste, tons	92,530
<hr/>	
Sent to mill, tons	470,981
Stamps working	220
Average working time, days	297.2
Tube-mills working, 250.7 days	4.2
Ore crushed, tons	470,056
Value of ore per ton, dwt.....	9.73
Recovery in cyanide plant, per cent.....	91.37
Cost of treatment per ton	\$1.12

MASS CONSOLIDATED MINING COMPANY

This Company was organized in 1899 and has a capital of \$2,500,000 in shares of \$25 each, of which \$2,300,000 has been paid in. Its properties include three old mines, the Ridge, Mass, and Ogima, and contain six copper-bearing amygdaloid beds. They are in T. 51 N., R. 38 W., and T. 50 N., R. 39 W., nearly 2500 acres in all. At the time of organization, \$8 per share was paid in, and \$15 per share has been paid in ten installments since that time, the latest being June 15, 1911. During 1912 operations were as follows:

Ore hoisted, tons	180,613
Ore milled, tons	132,891
'Mineral' produced, lb.	2,985,335
Copper produced, lb.	2,045,006
'Mineral' in ore, per cent	1.123
Copper in mineral, per cent	68.50
Copper per ton of ore smelted, pounds.....	15.39

The directors present the following report of the operations during the year 1912:

Income:	
2,045,006 lb. copper at 17.0205c.....	\$348,070
Real estate	284
Insurance on building burned.....	1,000
<hr/>	
	\$349,354

Expenses:	
Mining, development, surface, stamp-mill, freight, office and general expense, insurance, taxes, smelting, etc., and general Eastern expense	335,673
<hr/>	
Balance	\$ 13,681
Surplus assets on hand January 1, 1912.....	30,710
<hr/>	
	\$ 44,392

Assets are valued at \$142,031, and liabilities are \$132,684.

In his report the consulting engineer, F. W. Sperr, recommends doubling the rate of production, estimating that the production cost per pound of copper would then be: mining, 4.534c.; surface expense, 1.384c.; general expense, 0.074c.; taxes and insurance, 0.19c.; freight, 1.15c.; stamp-milling, 1.61c.; development, 1c.; a total of 9.934c. per pound. The development work during the year was highly satisfactory, 352,100 tons having been added to the reserves, making the net total, December 31, 1912, 727,000 tons. Development work is confined to the Butler and Evergreen lodes. At the B shaft in the drifts driven to the west on the Evergreen lodes, at No. 6 and 8 levels, the lode shows an increasing width of ore of milling grades. At the C shaft development has been on the Butler lode, on No. 5, 7, 8, and 9 levels, and has been satisfactory.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

COPPER AND GOLD ORES have been opened in several properties in Finland, Russia.

NISSEN AND ORDINARY STAMPS are to be tested against one another at the Carn Brea mine, Cornwall.

THE TERM 'DREDGE MINING,' in Victoria, Australia, includes bucket dredging, hydraulic sluicing by centrifugal pumps, and by the jet elevator.

GALVANIZED CORRUGATED IRON may be used with advantage in making leaching, agitation, storage, and other vats about a cyanide plant for temporary or permanent use. These are largely used in Australia and last for several years, even with rough treatment such as moving the vats nearer a sand dump as it is treated, to save long transport of the sand. Corrugated iron vats are made in all

TYPICAL WESTERN AUSTRALIAN GALVANIZED CORRUGATED IRON MECHANICAL AGITATORS.

sizes up to 30 by 8 ft., or even larger, the sides being of about 22 gauge corrugated, and the bottom of 18-gauge galvanized flat iron. The top sheet is turned over a $\frac{3}{8}$ -in. rod to form an annular brace, greatly strengthening the vat. The sheets are double riveted and soldered, and the inside is given two coats of P. & B. paint. Such vats are light, and may be curved and constructed at a mine with little trouble, saving the high transport costs of heavy steel vats. For small mine plants the corrugated iron vat is strongly recommended and will be found satisfactory.

DRILLING CONTESTS on Labor Day in several mining camps were as follows: At Sonora, Tuolumne county, California, three teams contested, drilling into granite. J. Page and F. Bartlett drilled $35\frac{1}{8}$ in., Pedro Bros. $34\frac{1}{16}$ in., and J. Wivell and J. Kahl reached 31 in. The first named were given the prize of \$150. At Hedley, British Columbia, five teams entered. Beam and Lyon drilled $30\frac{3}{16}$ in. McEachern Bros., of Olalla, in good style beat the former with $31\frac{7}{16}$ in. Hamilton and Liddlecoate, who having only two practices together before the trial, drilled $30\frac{1}{16}$ in. The Rossland team, Oscar Anderson and Andrew Sebla, gave a fine exhibition of drilling and drilled $34\frac{3}{4}$ in, and the Nickel Plate team, Jack Trewelah and Olle Holverseth, drilled $32\frac{1}{16}$ in. Altogether, it was the best drilling contest that has ever been held at Hedley, and was full of surprises from start to finish. At Cobalt, Ontario, results were as follows: (1) McKinnon Bros., Hudson Bay mine, $37\frac{3}{4}$ in., \$300; (2) McMillan Bros., $36\frac{1}{4}$ in., \$200; (3) Dunbrack and McKinnon, 31 in., \$100; Price Bros., $30\frac{3}{4}$ in.; Shea and Ross, $29\frac{3}{4}$ in. At Sumpter, Baker

county, Oregon, the winners were Goddard and Porter, from the Ben Harrison mine, who drilled $44\frac{9}{16}$ in.; followed by Baker and Dale, of the Bonanza mine, with $41\frac{15}{16}$ in.; Andregg and Nonoe with $41\frac{1}{8}$ in.; the Columbia mine team, Gutridge and Linville, with $39\frac{3}{4}$ in.; and Dodson and Roberts, from the Bonanza, with $38\frac{3}{4}$ inches.

CONCENTRATION is a mechanical process for the treatment of ores by means of which the valuable minerals are separated from the worthless portions by taking advantage of their physical properties, such as specific gravity, magnetism, and adhesion, the object being to concentrate the metal content into smaller bulk, by eliminating as far as possible, the portions that are of no commercial value. In the treatment of complex ores, it also serves as a means of separating two or more minerals which are not marketable while in combination, into several products, each of which can be sold or profitably treated by other processes.

ROLLS are successfully used for crushing material for concentrating plants, sampling works, cyanide mills, rock-crushing plants, cement mills, silica-sand plants, stamp-mills, phosphate works, chemical works, and converter plants. Being essentially machines for fine crushing, their work usually follows that of jaw crushers or gyratory crushers. They may be used to reduce rock and ores of various hardnesses, also clay and shale, and they can be operated either wet or dry. Rolls are being used more extensively from year to year because their operation is smooth, continuous, and economical when they are run under proper conditions.

BUCKET and ladder dredges operated by current wheels, came into use in the New Zealand goldfields in the early '70s. These machines were of crude construction and were limited to river-channel service. Ten years later, steam power was introduced, and this type of machine became so popular that during the next twenty years over 250 of them were placed in operation in New Zealand. Yet, while some attempts were made to build and operate machines of this type in the United States, especially in the California fields, the results were far from satisfactory until a New Zealand mining engineer came to this country, examined the Yuba River placers, and had constructed a small machine. This was the forerunner of the great dredges now in operation in California, Alaska, and other states.

A SYSTEM of belt-conveyors has just been completed at the Wasp No. 2 mill for removing the tailing from the leaching vats to the dump. On account of scarcity of water and danger of polluting a stream, it is out of the question to sluice these tanks. Six conveyors, each 70 ft. long, run under the discharge gates in the bottom of the vats. These conveyors dump on a belt 90 ft. long, running at right angles to the first mentioned, and this belt discharges on to a 150-ft. belt which delivers the tailing to the dump. Some difficulty has been experienced on account of moisture causing the tailing to stick to the belts, but it is hoped to overcome this by installing revolving brushes. With the belts the time of discharging a 420-ton vat has been reduced from 8 to $3\frac{1}{2}$ hours.

A CAREFUL COMPARISON of results obtained from a 16-ft. 5-in. and a 24-ft. tube-mill, working side by side at the New Goch mill on the Rand, showed the principal difference to be a saving of about 35% in power in favor of the shorter mill. The product, both in quantity and grading, was practically identical, according to E. Farrar, of the General Mining & Finance Corporation. In June there were 9922 stamps and 283 tube-mills at work on the Rand, and the proportion of tube-mills to stamps varied between 1 to 10 at the Consolidated Langlaagte, and 1 to 90 at the Durban Roodepoort. The stamp-duty varied between 5.4 tons at the West Rand Central, with 1 tube-mill to 20 stamps, and 21.49 tons at the Consolidated Langlaagte, with 1 tube-mill to 10 stamps. The relative numerical proportion of tube-mills and stamps are not the sole determining factors, as obviously the weights of stamps and screening used must be considered.

Metal Production of Oregon

The value of the mine output of gold, silver, copper, and lead, in Oregon, in 1912, according to Charles G. Yale, of the U. S. Geological Survey, was \$849,886, against \$669,016 in 1911. The total yield of gold was \$770,041, an increase of \$136,634 over the 1911 production. Of the gold output, \$580,945 came from placers. There was an increase in production from hydraulic mining of \$38,131, but there was a small decrease in the yield from drift and surface mines. About 50% of the placer gold recovered came from mines in Josephine and Jackson counties. The gold recovered from deep mines amounted to 28,103.21 fine ounces, valued at \$580,945, of which 27,278 oz. was derived from silicious ores, 616.40 oz. from copper ore, and 208.84 oz. from lead ores. The southwestern counties of Oregon (Coos, Curry, Douglas, Jackson, Josephine, and Lane), which form an extension of the California gold belt, made a combined production of \$217,565 in gold, and of \$10,343 in silver. Northeastern Oregon, comprising Baker, Crook, Grant, Malheur, and Wheeler counties, reported a gold production of \$552,476, of which Baker county contributed \$484,041, or 87.6%. The silver production of Oregon was 57,081 fine ounces, valued at \$35,105, compared with 45,221 oz., valued at \$23,967, in 1911. Of the 1912 production, 1941 oz. came from placers, 44,018 oz. from silicious ores, 10,555 oz. from copper ores, and 567 oz. from lead ores.

The copper production increased in Oregon from 93,136 lb., valued at \$11,642, in 1911, to 260,429 lb. valued at \$42,971 in 1912. All the copper except 6049 lb. was derived from ores mined in Josephine county. The production of lead in Oregon in 1912 was 39,317 lb., valued at \$1769. The output came from a small quantity of lead ore mined in Jackson county and from concentrate shipped from Lane county.

The Manufacture of Coke in 1912

By EDWARD W. PARKER

The following table, compiled by the U. S. Geological Survey, shows the production by states during the year.

State.	Establishments	Ovens built	Ovens building	Coal used, short tons.	Yield of coal in coke, per cent	Coke produced, short tons	Total value of coke..	Price of coke per ton.
Alabama	46	10,208	100	4,585,498	64.9	2,975,489	\$8,098,412	\$2.72
Colorado	15	3,588	0	1,473,112	66.0	972,941	3,043,994	3.13

Glass, Grinding, and Furnace Sand Production

The quantity and value of glass sand produced in 1912 was lower than in the two preceding years. The production amounted to 1,465,386 short tons, valued at \$1,430,471, as compared with 1,538,666 short tons, valued at \$1,543,733, in 1911, a net decrease in quantity of 73,280 short tons and in value of \$113,262. The glass industry was progressive in 1912, for building operations throughout the country made a steady demand for window and plate glass. Many glass factories, however, were hindered in operation by a shortage of labor. The average value of glass sand per ton was a fraction of a cent over 96c. in 1912.

Grinding and polishing sand had a good market in 1912. The production was 1,397,667 short tons, valued at \$667,750, as compared with 938,628 short tons, valued at \$521,761, in 1911, an increase in quantity of 459,039 short tons and in value of \$145,989. Engine sand likewise showed an increase for the year, as it is likely to do annually so long as rail transportation continues to expand. The figures for 1912 are 1,288,486 short tons, valued at \$428,928, an increase of 158,493 short tons and in value of \$17,620 over 1911, when 1,129,993 short tons, valued at \$411,308, was produced.

In 1911 the production of fire sand and furnace sand amounted to 672,140 short tons, valued at \$347,733, and in 1912 to 506,900 short tons, valued at \$346,000. This represents a decrease in quantity of 165,240 short tons and in value of \$1733 in 1912. Paving sand also was used in smaller quantity in 1912 by 156,042 short tons, but the value, nevertheless, was greater by \$19,071 than in 1911. The figures are 1,788,530 short tons, valued at \$670,680, in 1912, and 1,944,572 short tons, valued at \$651,609, in 1911.

Molding sand, which ranks second in quantity and value of production, broke all records in 1912, having for the first time exceeded 4,000,000 tons and passed the \$2,500,000 mark. The production in 1912 was 4,484,953 short tons, valued at \$2,718,398, as compared with 3,376,717 short tons, valued at \$2,132,469, in 1911, an increase in quantity of 1,108,236 short tons and in value of \$585,929.

EDITORIAL

THE Hall desulphurizing process is now in operation at the Balaklala smelter at Coram, California. We shall publish the results of the experimental work as soon as they are available.

BERING RIVER coal has been tested on the cruiser *Maryland* and, according to press reports, has been found unadapted to naval use. Why not, then, let the locomotives in Alaska have it?

REVIVAL of the mining industry has begun to be noticed by the smelting companies. One acute manager explains this as due to the shortage of money; finding it impossible to promote mines, the owners have been driven to working them, and this has resulted in discovery of additional ore-bodies.

MINNESOTA is one of the states that owns large tracts of mineral lands and the school fund is being rapidly built up out of the proceeds of royalties. While the charge for ore from state lands is less than that exacted by private land owners, it is estimated that the revenue derived this year will be nearly if not quite \$1,000,000.

ANNOUNCEMENT has been made that the Tau Beta Pi, an engineering honor society, and the Theta Tau, a professional mining engineering society, will conclave in San Francisco in the early part of September 1915. It is hoped that a large representation will report for the convention where a cordial reception is assured to those who make the pilgrimage across the deserts to this oasis on the Pacific Coast.

WHAT constitutes a fair attorney's fee must sometimes be decided by the courts. The Silver King Consolidated Mining Company recently won a judgment for \$905,000 against the Silver King Coalition Mine Company, but final payment of the money is prevented by disagreement over the charges of the plaintiff's attorneys, who have received \$37,000 and claim \$180,000 in addition. The Company concerned offered to pay \$96,800 in addition to the advances made, and when this was refused the matter was left to the courts.

GENERAL geology still forms a part of the work of the United States Geological Survey, despite occasional rumbles of discontent. To emphasize the fact, the Survey has just established a new annual volume into which is to be gathered for prompt publication the minor papers of a scientific rather than distinctively economic character, such as result from

each season's study. The first of these papers is a scholarly assay on 'The Origin of Colemanite Deposits,' by Mr. Hoyt S. Gale, in which is marshalled evidence for the belief that they are veins probably due to the reaction of boric acid vapors accompanying the extrusion of lavas, on lenses of limestone, themselves possibly hot spring deposits. The new series of papers should prove useful as well as welcome.

THE Edison process of concentration, which has been in the experimental stage for the past two years, has, according to Mr. Thomas A. Edison, been perfected to that degree where it can profitably be applied to a large majority of extremely low-grade ores where the metal content is contained in the slime. The process is characterized as being extremely simple and the investment is trivial compared with the results obtained. The first mill to use the process will be either the Waldorf or the Burleigh mill in the Georgetown district of Colorado, and judging from the tests, which have been conducted on a commercial scale, it is believed that the vast bodies of low-grade ore in the Silver Plume mines will prove of commercial importance when treated by this new process.

MINERS who have friction with the Forest Service and who are unable to get prompt service through local officials are requested to communicate with Mr. J. F. Callbreath, secretary American Mining Congress, Majestic building, Denver, Colorado. Those living in California may write direct to Mr. B. M. Newcomb, 200 Davis street, San Francisco, who has recently been appointed chairman of a California Forestry committee which is to coöperate with the miners in sifting and presenting points of difference between them and the Forest Service. As we recently intimated, we have had bad luck in eliciting information regarding specific abuses. The Forest Service expresses entire willingness to correct any errors that may have been made by its officials, and with the Mining Congress affording a friendly medium for presentation of his case, no miner having sound reasons for complaining need continue to suffer any injustice. It would seem to be time for complainants to present specific evidences of abuse of power if they have them.

ENGINEERING in connection with the operation as well as the building of a great exposition, is a most important matter. How complex it has become is suggested by a perusal of the 'Rules and Regulations' issued by the Division of Works of the Panama-Pacific International Exposition. It requires a volume of nearly a hundred pages to state the details of the service that will be supplied exhibitors and the terms under which operations must be conducted. It is proposed to furnish electricity for lighting, and on two power circuits, one with direct and the other alternating current. There will also be compressed air, steam, high-pressure water, and domestic water pipes, to say nothing of telephones and means of communication. Careful specifications have been drawn governing all details of building, and ample provision has been made for in-

spection. Intending exhibitors should apply for this book at once. Meanwhile rapid progress is being made in the erection of the great exhibition palaces being put up by the Exposition company itself.

THE pacific conquest of the Urals by foreign capital is coming to be looked upon with concern by the Russians and fears are expressed by the press of that country that the near future will see the world-famed platinum fields, together with the gold deposits and emerald mines, pass entirely into the hands of the foreigners. The Issovsky platinum mines in the Iss valley, which are the most important producers in the Urals, are controlled by French capital. In the goldfields the production is largely dominated by Belgian capital, and English interests are reported to be negotiating for the famous Berezhoff mines and the Miask estate. The mines of the late Baron Brevern are now being operated by English capital. The mining of precious stones, and emeralds in particular, is largely in the hands of the English. That alarm should be felt at foreign control of the mining industry is a most absurd stand, as history is proving every day. In the development of every new country and the expansion of industry in the old to meet the requirements of modern times, capital must be available and in large quantities. If it is not forthcoming from local sources, we fail to see the logic of an objection to the upbuilding of an industry which cannot fail to result in benefits to the locality in which it is founded, regardless of the source of the capital supplied. The mines of the United States, Transvaal, Mexico, South America, New Zealand, Korea, the Philippines, Rhodesia, the Malay states, and others, are living examples of the benefits wrought by foreign investment. If it be true, as often stated, that it takes an ounce of gold to produce an ounce of gold, the investment ounce that goes into the country is at least of equal fineness with the production ounce, that may come out.

Chilean Nitrate

The relation between mining and state is nowhere more pronounced than in Chile, where the nitrate industry has come to be the chief source of revenue for the government. The income from nitrate exportations has reached such proportions that the fear is expressed by many, that the decline of the industry, which cannot last forever, will result in bankruptcy, unless a readjustment of the nation's revenues is effected in the meantime. During the year ended June 30 the production amounted to 59,450,454 quintals (a quintal equals 101.41 lb.), as compared with 59,572,000 quintals for the preceding year. During this period the price of nitrate declined from \$2 per quintal to \$1.84 on July 1, 1913. As a result an agreement has been reached by the nitrate producers whereby the output will be restricted for a period of six months. By the present agreement 10 per cent of the output controlled by the nitrate interests will be withheld from the market. This restriction will amount to about 2,000,000 quintals or 90,000 tons during the next six months, which will reduce the supply to about that of last year. In

that the Chilean budget has been based upon an unrestricted output of 60,000,000 quintals, any curtailment of output will reflect in a decreased revenue, which it has been intimated might result in a change in the export tax. At the present tax rate the government revenue amounts to about \$30,000,000 per year from this source, which is almost 85 per cent of the nation's income. However, with the supply in sight sufficient to meet the present rate of production for a period variously estimated from 35 to 75 years, any immediate curtailment of the nation's revenue is precluded. In the current edition is presented a review of the Chile nitrate industry by Mr. Walter S. Tower, the illustrations for which are reproduced from our issues of January 15 and 29, 1910, in which numbers the nitrate situation was critically summarized by Mr. S. H. Loram. While the exhaustion of the nitrate fields is by no means in sight at the present time, with the impoverishment of agricultural lands in our own country and Europe and the merits of this class of fertilizer being demonstrated, the present rate of consumption will undoubtedly be greatly increased. It is reasonable to suppose that the present supply is far from being inexhaustible, and in addition to presenting a problem in national finance for future Chilean administrations, a new source of supply will have to be developed. Experiments toward this end are at present being conducted.

Desulphurizing Cobalt Ores

Preparation of complex sulphide ores for cyanidation has been one of the difficult problems before metallurgists. The standard method has been that of oxidizing the sulphur by roasting, but this, while effective, is expensive. Another method widely in vogue is by fine grinding to break the ore into such small particles as to permit satisfactory contact of the solution and the mechanically enclosed metals. Development of this 'all-sliming' process has greatly increased extraction, but it is clear that its success is contingent upon the metal being ultimately in free particles. Where it is chemically combined, as is gold and silver in the tellurides, or silver alone in argentite, and a wide range of arsenides and sulphantimonides, grinding alone is not sufficient. Cyanide solution acts upon these minerals but slowly, and there has been insistent demand for some chemical which would operate to accelerate the process.

At Kalgoorlie, and to a smaller degree elsewhere, the tellurides are decomposed by the use of bromocyanide, and at various times attempts have been made to use iodine or other solvents. It is unfortunately true, however, that these methods have not proved widely applicable and they are not always effective as regards sulphide ores.

Cobalt, which has surprised the world by reason of the richness of the silver veins worked, is, because of the complexity as well as value of the ores, becoming a great field for development of new processes of treatment. In our issue of August 9, Mr. Fraser Reid reviewed the present situation as regards milling in the district. The ores include native silver with nickel and cobalt, in the form of arsenides, arsenates, sulphides, sulpharsenides, sulph-

arsenites, antimonides, sulphantimonides, sulphobismuthites, and alteration products; truly a mixture to give the metallurgist pause. At the Nipissing high-grade mill a successful combination of amalgamation in an excess of mercury and of cyanidation has been developed and 170 tons, some of it containing over 2000 ounces per ton, was treated in August. By reason of the cost, this process is not applicable to low-grade ores. For some time experimental work has been under way at the Nipissing low-grade mill, with a view to discovery of a simple, cheap, and effective method of desulphurizing cobalt ores. We print this week the first account of these experiments and of the process that has been developed and is now in regular commercial operation, 7824 tons having been treated in August. For the same month the total refinery product from the two mills of the Nipissing company amounted to 553,698 ounces of silver.

The account of the new process has been written by Mr. J. J. Denny, metallurgical chemist for the Nipissing Mines Company, and the discoverer. The process will be seen to be interesting from many points of view, and we consider it the most significant advance in cyanidation made this year, just as the combined amalgamation-cyanidation process perfected at the Nipissing high-grade mill, was the sensation of 1912. As to the process itself, Mr. Denny's description is so clear as to need no comment. It has been in the textbooks for years that caustic alkalis reacted to decompose sulphides, though little use has been made of the knowledge. In 1910 a patent was issued to Messrs. Paul W. Avery and Eugene C. Knowles for the use of caustic soda in the presence of a suitable oxidizing agent, to decompose sulphides preparatory to cyanidation. This was based upon work done on the so-called 'blue' or telluride ores of the Black Hills. The supply of the ore proving inadequate, no large mill to utilize the process was built. Mr. Denny uses caustic soda but so as to generate nascent hydrogen, a powerful reducing agent, by the reaction between it and metallic aluminum. It might be thought that the aluminum acts merely as a catalytic body accelerating a normal work of the alkali, but the equations written by Mr. Denny show that instead it enters into the series of reactions, and is slowly consumed. How widely useful the new process may prove is uncertain. In the Nipissing mill it results in an additional saving of one to four ounces of silver at the price of one. This is a satisfactory but not large margin. This may, however, be a factor of the particular ore treated, and elsewhere larger savings may result. Certainly there is little to be gained in the metallurgy of simple ores and any process such as this, that shows improvement in treating complex ores, is in line with what must be the main developments of the future. We congratulate Mr. Denny on his discovery, and we felicitate the Nipissing company. Any concern has little to fear that, in addition to large mines of rich ore, possesses in its regular and consulting staff a body of engineers that in two years perfects the amalgamation-cyanidation process of one mill, and the desulphurizing-cyanidation plan of treatment in another.

Desulphurizing Silver Ores at Cobalt

By JAMES J. DENNY

Until about a year ago there was no successful all-cyanidation process for the treatment of Cobalt silver ores, the metal content from the low-grade wall rock being recovered largely by mechanical concentration. These ores were found to be fairly amenable to cyanidation, but the working solution rapidly became foul and lost its dissolving efficiency, and the consumption of cyanide was heavy.

Owing to these difficulties, until the advent of the Nipissing low-grade mill in the latter part of 1912, cyanidation had played a minor part in the

on the Nipissing property contain considerable amounts of these minerals, and my experiments were therefore directed to discover some inexpensive chemical or electrical process for breaking up these refractory compounds and so rendering them amenable to cyanidation. Working along these lines, I finally discovered that all of these minerals excepting dyscrasite were readily decomposed into their respective elements when brought into direct contact with aluminum in an alkaline solution. This preliminary reducing treatment left the silver

THE NIPISSING LOW-GRADE MILL.

silver production of the camp, being employed in three mills, the O'Brien, Dominion Reduction Co., and the Buffalo, and in each case merely as an adjunct to mechanical concentration. In the fall of 1911, therefore, I undertook a series of experiments in connection with the projected Nipissing low-grade mill to test the possibilities of several proposed methods of treatment and to discover, if possible, an all-cyanidation process that would improve on the general practice.

Variations in Results of Experimental Work

After a considerable amount of experimenting I found that my results varied greatly, and to determine the cause I ran separate tests on the principal silver-bearing veins. My experiments showed that while some veins gave excellent results by ordinary cyanidation methods, the tailing from the treatment of other veins was persistently high, owing to the presence of varying amounts of the complex minerals, pyrrargyrite, tetrahedrite, proustite, dyscrasite, and argentite. Some of the veins

in a spongy metallic state, and when followed by the usual cyanidation process the results were found to be very satisfactory.

In order to study their behavior in detail, specimens of exceptional purity of each of these minerals were secured, and samples for further experiments were prepared by grinding the minerals with quartz, in a porcelain mortar, to pass a 100-mesh screen. The attempt was made in each case to dilute the silver-bearing mineral so as to give as nearly as possible a sample that would assay 30 oz. silver per ton. The results of three sets of experiments are given below.

In experiment A, ordinary cyanidation is used; experiment B is straight cyanidation with the addition of enough lead acetate to combine with the calculated amount of sulphur in the sample. In experiment C the sample was given a preliminary reducing treatment for ten hours in a 0.25% solution of caustic soda, dilution 2 to 1 in an open-mouth bottle in which were placed three 6 by $\frac{1}{2}$ by $\frac{1}{32}$ -in. strips of sheet aluminum. The strips

were then removed, the sample filtered and given the ordinary cyanidation treatment without washing or drying.

In each case 100 gm. of sample was taken. The ordinary cyanidation treatment in all the experiments consisted of treating the ore with a 0.25% cyanide solution, dilution 3 to 1, and agitating for 48 hours, lime being added at the rate of 5 lb. per ton. Agitation was effected by rolling in large open-mouth bottles.

Discussion of Results

Experiment A, giving results from ordinary cyanidation treatment, requires little comment. All the results are low, and only in the case of argentite does the extraction approach a commercial figure.

Experiment B shows that the addition of lead acetate in every case is a detriment as compared with ordinary cyanidation except with argentite where the extraction is raised to a marked extent. It is interesting to note that similar results were obtained by Theo. P. Holt at the Utah School of Mines in 1909.¹

Experiment C shows a remarkable increase in extraction as a result of the preliminary reducing treatment in every case except with argentite, where the results are lower than in experiment B. This was owing to the poor contact with aluminum sheets during the preliminary reducing treatment as a result of the tendency of the mineral to float as a black scum. Further experiments where granulated aluminum was substituted for the sheet metal gave 90% extraction as a result of the better contact obtained.

In practice, the system of agitation employed gives a better contact and therefore a better reduction and higher subsequent extraction than the rolling agitation employed in these experiments.

The Reducing Treatment and Probable Reactions Involved

By the preliminary treatment the silver, and in part at least, the antimony and arsenic, are reduced to the metallic state, and are so found. The reduction is accomplished by the nascent hydrogen resulting from the action of caustic soda on the aluminum according to the following equation:

(1) $2Al + 2NaOH + 2H_2O = Na_2Al_2O_4 + 6H.$

The probable reactions involved in complete reduction are indicated by the following equations:

the metallic state in practice, and the investigation of the subject is rendered difficult by reason of secondary reactions by which the arsenic and antimony are possibly redissolved to form arsenates and antimonates by the excess caustic of the reducing solution, and the protective alkali of the cyaniding solution. The working solution shows the presence of these compounds, but in practice they are found to have no detrimental effect either in the reducing or the cyaniding treatments. The solution assays, antimony 0.0084% and arsenic 0.026 per cent.

Necessity of Fine Grinding

Further experiments along these lines established the necessity of fine grinding to raise the extraction to the desired point. The results of one series of experiments are given in table No. 2. As the samples used in the previous experiments were used up, new samples had to be prepared. These were ground to pass a 200-mesh screen, 12.4% of this product being a fine -200-mesh sand, and were calculated to have as nearly as possible the same silver content as the former samples. The experiments with the addition of lead acetate were discontinued and the plain cyanide treatment was run against cyaniding after the desulphurizing treatment. The same conditions were maintained as described in experiments given in table No. 1.

Average		27.68	9.44	66.67	1.69	93.87

¹See *Mining and Scientific Press*, April 17, 1909, and 'More Recent Cyanide Practice,' p. 186.

My experiments also established the fact that

the degree of fineness required varies with the amount of antimony present. Some results from plain cyaniding that show this clearly are given in table No. 3. The method of preparing the samples and the conditions of the experiments were the same as before.

TABLE No. 3

Commercial Tests

I then undertook a large number of tests on a commercial scale, using ordinary run-of-mine ore to determine the following points: (a) the effect of the reducing treatment; (b) the time of treatment; (c) the degree of eomminution required to give the best economie results.

In table No. 4 are given the results of two series of experiments, showing the effect of the reducing treatment as against plain eyaniding, and giving the results of different times of treatment. In these tests 50-lb. echarges were used, and desulphurizing was effected by agitating for ten hours by meehanical means in a small tank, 24 by 18 in., with paddles to which were tacked 4 by 8-in. sheets of aluminum. When not otherwise stated, the eonditions maintained were the same as in previous experiments. The samples used in these experiments were ground in a pebble-mill to pass a 200-mesh screen.

TABLE No 4										
H—Plain cyanide treatment. Cyanide strength, 0.25%; dilution, 3:1. Lime, 5 lb. per ton of ore.										
Head assay, oz. per ton	Residue after 24 hours...	Extraction, per cent...	Residue after 48 hours...	Extraction, per cent...	Residue after 72 hours...	Extraction, per cent...	Residue after 96 hours...	Extraction, per cent...	Residue after 120 hours...	Extraction, per cent...
26.13	5.8	77.80	3.76	85.61	2.76	89.43	2.6	90.04	2.3	91.19
25.45	6.2	75.65	4.90	80.74	3.80	85.06	3.6	85.85	3.1	87.81
I—Desulphurized before cyanide treatment. Cyanide strength, 0.25%; dilution, 3:1. Lime, 5 lb. per ton of ore.										
26.13	2.8	89.28	1.64	93.70	1.58	93.95				
25.45	3.0	88.21	2.22	91.22	1.70	93.3				

These results show clearly that on the run-of-mine ore the desulphurizing treatment raises the extrac-tion appreciably and greatly reduces time. These and similar experiments establish the efficacy of the desulphurizing process and point to 48 hours as the most economic time of treatment.

Degree of Comminution

It was early apparent in this preliminary investi-gation that extremely fine grinding was absolutely essential to give a high extraction in the desired time (48 hours), and this fact has been substan-tiated by many later experiments.

Table No. 5, giving the results from plain cyanid-ing on sized material, shows this clearly. For these experiments, two 50-lb. samples of mine ore were crushed, one to pass through a 150 and the other a 200-mesh screen, after which they were treated for 48 hr. in a 0.25% cyanide solution (dilution 3:1) with the addition of 15 lb. of lime per ton of ore.

TABLE No. 5					
J Through 150 mesh. Sand + 200 mesh, 0.84% Sand — 200 mesh, 42.4%			K Through 200 mesh. Sand — 200 mesh, 16.36%

28.6	3.6	87.4	28.6	2.48	91.3

The same fact was established by means of de-tailed screen analysis of mine ore, the results of which are not included here.

Aluminum Precipitation

The circumstances that led to the adoption of aluminum preeipitation in connection with this pro-cess together with the results of some of my experi-ments, have already been published by E. M. Ham-ilton,² but a few further remarks at this point may be of interest.

In my preliminary experiments, zinc was used for preeipitation and for a time all was well, but at the conelusion of a series of experiments on ore that eontained considerable amounts of the eomplex minerals, I was surprised to find my work-ing solution badly fouled and proceeded at once to investigate the eause. The deterioration of the working solution has usually been attributed to the

complex silver minerals, and one writer explains the action as due to the formation of soluble sul-phides, sulphocyanides, and ferrocyanides. My in-vestigations showed that not only were these eom-pounds formed to some extent, but, which is more important, proved the presenee in small amounts of soluble arsenites, thio-arsenites, antimonites, and thio-antimonites. These eompounds are strongly re-ducing and are oxidized to arsenates, antimonates by the dissolved oxygen of the solution, the action being accompanied by the decomposition of cyanide.

²Eng. & Min. Jour., May 10, 1913.

The complex minerals were clearly not to blame, as those had already been reduced to their respective elements by the preliminary desulphurizing treatment, and, while the formation of the above-named compounds accounts, in part at least, for the heavy consumption of cyanide, they are not present in amounts large enough to seriously affect the efficiency of the working solution. In any case, the oxidation of these compounds by aeration and the use of oxidizers would restore the solution to normal efficiency if they were the cause of its deterioration, but these were found to be without effect. The cause of the trouble then was evidently to be found elsewhere.

I then started a new series of experiments with a fresh solution and followed the action closely, testing the solution after each step in the process. The results proved favorable in every case until the solution passed over the zinc-box, after which it was found that its dissolving efficiency was greatly impaired. The cause of the trouble was therefore shown to be the use of zinc as a precipitant, and further experiments, given in the article already referred to, proved this conclusively.

Fatigue of Solution

In what form the zinc exists in the solution, and why, in conjunction with arsenic and antimony, its deteriorating effect on the dissolving power of the solution should be so marked is not apparent.

It was found that while the addition of oxidizers to the solution had no effect, after allowing it to stand for eight days the solution recovered its original dissolving power. No explanation of this peculiar phenomenon has suggested itself, and as by this time it had been proved that the use of aluminum dust instead of zinc as a precipitant would solve the whole difficulty, investigation of this very interesting subject was dropped for lack of time to continue it further.

The method of treatment as outlined above was immediately put into practice at the Nipissing low-grade mill on the recommendation of Charles Butters, the consulting engineer. As this is the first and as yet the only commercial application of the desulphurizing process, a brief description of the practice followed here will be of interest.

Nipissing Low-Grade Mill

The Nipissing low-grade mill is at Cobalt, Canada. The high-grade ores of this property have been treated for the last three years in the high-grade mill by an amalgamation and cyanidation process yielding the silver content directly as bullion.³

The object of the new low-grade mill was to treat the low-grade wall rock by cyanidation and likewise recover the silver in the form of fine bullion. The mill was designed and constructed by James Johnston of the Butters Engineering Co., and owes much of its success and smoothness of operation to his experience and foresight. Operations on a small scale were commenced on November 16, 1912, and

after a short period of minor adjustment started at full capacity. Up to the present it has continued to run with gratifying success.

Nature and Analysis of Ore

The rock is mainly the Cobalt series of conglomerate and is very hard and tough. The following is an analysis of the average run of mine ore:

Per cent.		Per cent.	
Ag	0.106	Pb	0.064
Cu	0.270	CaO	9.020
As	1.880	MgO	4.330
Fe	1.920	Al ₂ O ₃	10.030
S	0.640	CO ₂	11.060
Bi	0.010	Insolubles	59.840
Ni, Co	0.730	Hg	Trace

Washing Plant

The washing plant, where the ore is crushed in breakers and given a preliminary jigging treatment, is not a part of the mill proper, as the concentrate from this section is credited to the mine. The ore from the mine averages about 60 oz. per ton, and the tailing from the washing plant as sent to the mill proper averages about 28 oz. per ton.

Stamping and Fine Grinding

In the mill proper, the ore is crushed by stamps in a 0.25% solution of caustic soda, lime being added to the extent of 5 lb. per ton of ore. The lime is used merely for settling, to facilitate subsequent decantation of clear solution back to the battery storage tank, the alkalinity for cyanidation treatment being furnished by the caustic solution. The fine grinding is effected by a closed system of tube-mills and classifiers, two of the tube-mills being used to regrind the battery discharge, and the other two for the ultimate fine grinding. Of the final product, only 0.5% remains on a 200-mesh screen, 16 to 20% is a fine -200-mesh sand, and the remainder an impalpable slime. After settling and decanting the solution, the thickened slime passes on to the reducing treatment.

Desulphurizing Process

The pulp is given a preliminary desulphurizing treatment by being passed through a tube-mill which is charged with aluminum ingots. The final treatment is given by lining the filter stock tank with aluminum plates and agitating for about ten hours by mechanical means. From the stock tank the pulp is drawn off by the filters as required. After filtering, the cake carries 26% alkali solution as moisture, and is thence discharged without washing to the cyanide tanks.

Cyanide Treatment

The cyanide treatment consists of agitating the pulp for 48 hr. in a 0.25% cyanide solution, dilution 2.5:1. The pulp is then settled, the excess solution decanted, and after being again agitated the pulp is pumped to the stock tank for filtering.

Precipitation and Treatment of Precipitate

As already mentioned, the pregnant solution is precipitated with aluminum dust. The details of the mill practice, together with a statement of costs, are included in the article by E. M. Hamilton. The

³For a description of this mill, see T. A. Rickard, *Min. Mag.*, June 1912; R. B. Watson, *Eng. & Min. Jour.*, December 7, 1912.

precipitate is then sent to the refinery of the high-grade mill, where it is melted in a reverberatory and refined, the bullion averaging 999 fine.

Early Difficulties

When the process was first put into operation, the mechanically agitated stock tanks were depended on for the desulphurizing treatment. Here the aluminum plates were soon found to form a coating which was thought to be a calcium aluminate, and the reducing action was seriously retarded. To overcome this difficulty, the tube-mill charged with aluminum ingots was added. This kept the aluminum clean and bright, but the aluminum consumption was increased as a result of the wear on the ingots. Lately, however, the trouble has been found to be due to impure aluminum containing iron and silica; sheets of pure aluminum are found to remain clean and to have no tendency to form a coating.

Comments on Practice

Crushing a neutral ore in an alkaline solution is unusual, though not unknown, in cyanidation, and the 26% of the alkali solution passing over with the cake to the cyanidation tanks will be criticized as being contrary to general practice. However, instead of being detrimental as is ordinarily maintained, in this particular case, namely, with Cobalt ores where the native silver is associated with antimony, the addition of alkali to the cyaniding solution has proved to be a decided benefit. Daily tests, running the working mill solution against fresh cyanide solution, show in every case an increased solvent power of from 0.2 to 0.5 oz. of silver per ton of ore in favor of the mill solution. In this connection, the behavior of the mineral dyscrasite is interesting. As mentioned at the beginning of this article, the reducing treatment has no effect on this mineral, probably due to the fact that it is a complex of variable composition of the metals, silver and antimony, and does not contain sulphur. However, the results from treating this mineral by plain cyaniding, compared with the results of similar treatment, after the preliminary reducing treatment, show a decided advantage in favor of the latter, owing to the beneficial action of the caustic soda solution during cyanide treatment. A further advantage of the caustic in the cyanide solution is the fact that it is necessary to precipitation with aluminum dust and saves the addition of caustic at that point.

Summary

The outstanding essential principles of the practice followed at the Nipissing low-grade mill are, therefore: (1) the extremely fine grinding; (2) the preliminary reducing treatment before cyanidation; (3) the use of aluminum-dust precipitation. In July the mill treated 234 tons per day of 27-oz. ore, and below the stamps made an extraction of 93.16% actually recovered in bullion.

Costs

As the mill has been running less than a year, the compiling of representative figures showing

costs is a matter of difficulty. In connection with the desulphurizing treatment, treating 7268 tons per month, the following data are available:

COLLECTING, DESULPHURIZING, AND TRANSFERRING OF PULP

	Per ton.
Labor	\$0.050
Supplies (aluminum, 0.81 lb.; caustic soda, 1.46 lb.; lime, 5 lb.).....	0.347
Power	0.027
Workshop	0.008
Total	\$0.432

ALKALI SOLUTION, FILTERING AND TRANSFERRING

	Per ton.
Labor	\$0.069
Supplies	0.006
Power	0.028
Workshop	0.002
Total	\$0.105

The desulphurizing treatment effects a saving of from one to four ounces per ton, depending on the amount of refractory minerals present, at a total cost of 54c. per ton.

Application to Gold Cyaniding

A promising field for investigation is the possible application of this desulphurizing process to the cyanidation of refractory gold ores. A sample of sylvanite was found to reduce readily to metallic gold and tellurium, but lack of time and the difficulty of obtaining a pure sample of the gold telluride for experiments, have prevented further investigation on these lines. However, I have every confidence that the desulphurizing process will prove to be a valuable adjunct to the treatment of these ores by cyanidation.

In conclusion, I wish to acknowledge with gratitude the interest taken by R. B. Watson, general manager, in my preliminary investigations and encouragement afforded by him during the development of the process as established above.

Flooding Culebra Cut

All steam-shovel operations in Culebra cut proper in the Panama canal were discontinued on September 15, and between that date and October 5, when water will be admitted, all equipment and other material to be recovered, including more than 36 miles of track, must be out of the 9-mile channel between Gamboa dike and Pedro Miguel locks. It is the intention to retain 10 of the best conditioned shovels in service, using them in the work of removing material from the east and west banks, near Culebra, to lessen the danger from slides. About six of these machines will be employed on the east bank, and four on the west bank, probably until May 1914, and an organization sufficient to man and look after the shovels is now under consideration. Water will be admitted to Culebra cut, under the above schedule, on Sunday, October 5, five days in advance of the date set for the destruction of Gamboa dike. The means employed will consist of four 26-in. pipes extending underneath the dike, now used in pumping the drainage water out of the canal.

Origin of Lead, Zinc, and Silver in the Coeur d'Alene—I

By OSCAR H. HERSHEY

Originally the lead, zinc, and silver, whose sulphides now constitute the commercial ores of the Coeur d'Alene district of Idaho, were widely diffused in the igneous rocks of the earth. Unless one seriously entertains the hypothesis that important quantities of these metals have been brought to the earth in the course of ages by meteorites and cosmic dust, it must be conceded that practically all of them were present in the crystalline rocks before the presumed beginning of erosion and sedimentation on the earth's surface. That minute quantities of these metals are widely disseminated in igneous rocks today has been demonstrated by the careful work of the chemists. F. W. Clark¹ has gathered much of the evidence. He mentions that G. Forehammer found traces of silver, lead, and zinc, with other metals, in a series of rock samples; and it is well known that F. Sandberger, in an elaborate series of researches, found that lead and silver are contained, with other metals, in the dark silicates of many rocks. Lead was detected by G. F. Becker in the fresh granites near Steamboat Springs, Nevada, and W. F. Hillebrand found it in the porphyries of Leadville, Colorado. Silver, and in one sample zinc, were also found. J. D. Robertson determined an average content of 0.004% lead and 0.009% zinc in granite, porphyry, and diabase from the Archean deposits of Missouri. L. Duclafait claims that zinc may always be detected in rocks. In a large series of igneous and metamorphic rocks from British Guiana, J. B. Harrison found lead in 5 out of 23 samples tested for it, and 8 rocks yielded silver. Traces of silver in diabase and diorite near Washoe, Nevada, have been reported by G. F. Becker; in the quartz porphyry of Eureka by J. S. Curtis; in the eruptive rocks of Custer county, Colorado, by S. F. Emmons; in volcanic ash from two points in the Andes by J. W. Mallett; and it is known in ash from Cotopaxi and Tunguragua.² Mr. Clark concludes that "the heavy metals are widely disseminated, both in old and in recent igneous rocks, from which, by proper methods, they can be concentrated." A similar opinion is expressed by C. R. Van Hise,³ who says: "As to the original source of the sulphides, it is well known that sulphide of iron occurs as an original constituent of igneous rocks. Probably the same is true of other sulphides, but as their quantity is very much less they have been little noticed."

Presence of Metal in the Archean Rocks

For the purpose of this discussion, it is only necessary to go back to the era of the known Archean rocks. As these rocks included a great amount of igneous material, it may be presumed

that lead, zinc, and silver salts were present in a diffused form in large masses of them. In distribution, the salts of the metals probably did not approach uniformity, considerable areas being perhaps nearly free from them, while in others they may have been present in amounts comparable with those found in the Archean rocks of Missouri.

Influence of Weathering

Weathering and erosion cut deep into these ancient rocks and swept their disintegrated particles into bodies of water to form the Algonkian sedimentary rocks. The breaking down of immense bodies of lead, zinc, and silver-bearing rocks must have freed the sulphides of these metals, and, in an oxidized condition, they were necessarily carried into the permanent bodies of water, chiefly the sea. They may have traveled in solution or as exceedingly finely divided particles of sediment. It matters not which view one entertains, there seems no escape from the conclusion that, if these metals are and always have been diffused widely in igneous rocks, considerable quantities of them were present in the water-basins of the Algonkian period. The same argument applies to all subsequent time. If these salts were carried as sediment and did not go into solution, they must have settled with the other sediments and become a portion of the stratified rocks. If carried in solution and never precipitated, they have been accumulating in the ocean for many millions of years. Minute quantities of lead and zinc are known to be present in sea water, but there is no very definite evidence as to the amount. The presence of silver (with gold) is better known, and, according to A. Liversidge,⁴ it amounts to 1 to 2 grains per ton. It may be that the quantity of gold and silver is not such as to necessarily imply precipitation from sea water since the Archean era, but it is my impression that in the case of lead and zinc this could hardly be true. At any rate, it is reasonable to suppose that lead and zinc followed the same course as iron, manganese, and copper.

Occurrence of Coeur d'Alene Deposits

The ore deposits of the Coeur d'Alene district occur in the Belt series of altered sediments of pre-Cambrian age. The petrography of these rocks has been thoroughly studied by F. C. Calkins,⁵ who has subdivided them into the Prichard formation, composed in greater part of argillite, overlain in order by the Burke quartzites and silicious shales, the Revett quartzite, the St. Regis indurated shales and sandstones, the Wallace calcareous shales, sandstones, impure limestones, and argillites, and the

⁵The Geology and Ore Deposits of the Coeur d'Alene District, Idaho, by F. L. Ransome and F. C. Calkins, Prof. Paper 62, U. S. Geol. Surv., 1908.

Striped Peak sandstones; the whole having a presumed thickness of over 17,200 ft., of which over 8000 ft. is accredited to the Prichard. My section of that portion of the series which is present in the vicinity of Wardner comprises a thickness of 19,800 ft.⁶ The microscopic features of these rocks are very well treated by Mr. Calkins. He shows that they consist chiefly of variable proportions of only two minerals, quartz and sericite. There are beds of practically pure quartzites over 100 ft. thick, but usually the quartz grains are separated by flakes of sericite. In the shales and slates there is a relatively large amount of sericite, and all the grains are very fine and tend to be developed in alternate layers of different fineness. It is evident that these sediments originally varied from practically pure quartz sand to fine mud. Whether they were laid down under marine, lacustrine, or continental conditions is of no importance in this connection, for in any case they are clearly the fine débris from a great land area of Archean rocks, and if lead and zinc are as widely distributed in igneous rocks as they appear to be, salts of these metals must have been present in the water in which the Belt sediments were deposited, and it is entirely reasonable to suppose that to some extent they became incorporated with the sediments. I would expect them to be deposited with the fine mud rather than with the clean sand. If these minerals came into the waterbody as sediments, they were doubtless in an exceedingly finely divided condition, and in the sorting of the materials by wave and current action, would go into the mud instead of the coarser quartz sand, just as in the concentrating mills the sulphides of lead and zinc go proportionately more into the slime than into the sand. If the lead and zinc salts were in solution in the waterbody, it would seem that conditions for their precipitation would be much more favorable on the mud-flats than on the clean quartz sandbars.

The Quartzite Rocks

In the relatively pure quartzites and ordinary sericitic quartzites, nearly all the material is transparent in thin section. Carbonate of iron is widely disseminated in these rocks, and minute quantities of lead and zinc in the form of carbonates might occur with the siderite and not be apparent under the microscope. However, the distribution of the ore deposits leads me to the conclusion that this is not the form in which lead and zinc may be diffused in the rocks of the district. The St. Regis, and in places the Burke, contains purple bands in which the coloring matter, as shown by Mr. Calkins, is hematite dust. Without doubt the iron was an original constituent of the sediments, though not necessarily as hematite. It may have been precipitated as limonite, from iron carbonate, and converted into hematite during the regional metamorphism of the rocks. The same conditions which precipitated the iron might have precipitated lead

and zinc salts. However, the ore deposits cannot be traced to the purple Burke and St. Regis as a source. The frequent association of lead and zinc ores with limestones might point to the calcareous Wallace formation as the horizon of the presumed diffused mineralization, but to this I have the same objection as above, namely, that the distribution of the ore deposits emphatically precludes the Wallace calcareous shales, limestones, and even the carbonaceous argillites from serious consideration in this connection. The one formation in the Coeur d'Alene district which does not seem open to any of the above objections is the Prichard argillite. This contains opaque dust, doubtless chiefly carbon. The formation is also characterized by the presence of considerable pyrite, which, in its present form, is secondary to the regional metamorphism, but in some form was probably originally present in the sediments. Mr. Calkins mentions also as accessory minerals rutile, zircon, tourmaline, siderite, magnetite, biotite, chlorite, and a very small amount of calcite. The two minerals which may be presumed to have been originally present in the Prichard mud and to have been capable of influencing the deposition of lead and zinc sulphides, are carbon and iron sulphides.

Metal Occurrence

There is no very definite evidence of as wide diffusion of lead and zinc in the sedimentary as in the igneous rocks. F. W. Clark mentions, in the volume before cited, that L. Dieulafait detected zinc in hundreds of samples of Jurassic limestone from central France; that J. B. Weems found by analysis of nine samples an average of 0.00326% lead and 0.00029% zinc in limestones and dolomites of the Dubuque region, Iowa; that J. D. Robertson found in the Silurian limestones of Missouri lead up to 0.00346% and zinc up to 0.1536%; and that A. M. Finlayson secured similar results in his study of the British lead and zinc deposits. It is recognized that in all these cases at least some of the diffused mineral may have been introduced in connection with the formation of the commercial ore deposits. H. F. Bain⁷ argues that in the Wisconsin district the commercial ores have been concentrated from diffused mineralization that was deposited with the sediments, because of the known absence of igneous rocks of as late date as the sedimentary beds, of the absence of deep extending faults, of the presence under the area of unbroken sheets of artesian water in sedimentary beds, and of the sufficient evidence of the origin of the ores by this agency. G. H. Cox⁸ holds that "the Maquoketa shale contains lead and zinc compounds as original minerals." E. R. Buckley⁹ thought that the ore deposits which are found in the Mississippian limestone in Missouri were concentrated from diffused deposits in the Pennsylvanian shale, limestone, and coal. C. R. Van Hise¹⁰ expressed the opinion that the lead and zinc sulphides of the Mississippi Val-

⁹'Types of Ore Deposits,' p. 127, 1911.

¹⁰'A Treatise on Metamorphism,' p. 1105.

ley "are segregated from sulphides in limestones. These sulphides were derived from the sulphides of earlier rocks which were probably transformed to sulphates, transported to the sea, and in the sea, as shown by T. C. Chamberlin, precipitated as sulphides at the same time the limestone was formed."

Carbon as a Precipitant

As to the precipitant in the segregation of the diffused minerals, he says: "Another clear case of the direct reduction of oxidized salts by organic matter is that of the lead and zinc deposits of the Mississippi Valley. In Wisconsin, as shown by W. P. Blake, lead and zinc were precipitated by the organic matter of the oil rock, and in Missouri, as shown by H. F. Bain, by the organic matter of the Devonian shales." Thus there is precedent for the suggestion that in the Idaho region lead and zinc sulphides may have been precipitated from the Prichard waterbody either by the direct action of the carbon in the mud or by the carbon precipitating iron sulphides and the latter being partly replaced by lead and zinc sulphides. It is possible that these metals are much more irregularly distributed in the sedimentary than in the igneous rocks as they were only precipitated when and where conditions were unusually favorable. In this connection it must be noted that they are more likely to occur in the older than in the younger sedimentary rocks because the former were more directly and extensively derived by the erosion of igneous rocks. The Belt and the early Cambrian sediments were especially favored in this regard, but even in the Idaho region, conditions favorable to the formation of diffused deposits may have been limited to a very small part of Algonkian time and to a relatively small portion of the Belt waterbody.

Since early Tertiary time some millions of tons of lead and zinc have been eroded from the Coeur d'Alene district. Rather elaborate tests made in connection with some debris litigation have shown that exceedingly small quantities of lead have remained in the alluvium of the Coeur d'Alene river, and that there is practically no lead in solution in the river water, that is, scarcely any detectible by ordinary means. There is underground evidence that very little of the lead and zinc have gone to form new deposits in the district; it is, therefore, incontrovertible that the Coeur d'Alene river has carried millions of tons of these metals out of the district. Some of them may have found a temporary resting place on the bottom of Coeur d'Alene lake, but all must ultimately reach the Pacific ocean, where they may be precipitated as diffused deposits in the sediments. If, instead of being derived from a small number of highly concentrated deposits, the minerals came from the disintegration of many cubic miles of lead and zinc-bearing igneous rock, the result so far as the lead and zinc content of the marine sediment is concerned, might be the same.

Genesis of Lead-Zinc-Silver Deposits

Two principal working hypotheses as to the genesis of the lead-zinc-silver ore deposits of the Coeur d'Alene district are before the public. One is a

modification of what would be termed by H. F. Bain the sedigenetic hypothesis, and the other is the magmatic hypothesis. Both refer the ultimate source of the metals to igneous rocks. The former implies that the lead, zinc, and associated silver minerals became diffused in certain bands of the Belt sediments, by the process described in the preceding pages, and subsequently concentrated into the present commercial ore deposits as suggested in my paper on the Wardner district.¹¹ The latter hypothesis implies that these minerals remained below the Belt rocks until a comparatively late period when they were expelled from the deep-seated portions of a magma, which crystallized into quartz monzonite and related rocks, and were deposited in the Belt rocks. F. L. Ransome is the chief exponent of this magmatic theory.¹² Others have supported it in oral communications. Another geologist has advanced the theory that the ore deposits were derived by downward leaching from diffused minerals either in a basalt cover, long since removed from the Coeur d'Alene, or in the higher portions of the Belt rocks themselves. As this hypothesis has not been formulated publicly, and as it is so strongly opposed by evidences that the mineral-bearing solutions have moved upward instead of downward, I will not discuss it further.

Prichard Type of Lead-Zinc Deposits

The Prichard areas in the Coeur d'Alene district are characterized by what may be called the Prichard type of lead-zinc ore deposits. In this type, zinc sulphide, presumably sphalerite, is abundant, and the silver ratio is very low. The blende varies from a pale yellowish gray to a dark-brown color. In some veins there is a rather intimate mixture of the blende and galena, but usually they are fairly well separated. In one mine in the valley of the north fork of the Coeur d'Alene river which I have visited, the zincblende is often in masses 1 to 3 ft. thick and 6 ft. long. Elsewhere in this mine, blende and galena with some quartz and calcite are intergrown. In other places the galena tends to follow seams and may be later than the blende. There are small quantities of chalcopyrite and pyrite, but no siderite. There are said to be 8 to 10 oz. silver per ton to 70% lead in the lead shipments, and practically no silver in the zinc shipments. A specimen of blende assayed 61.5% zinc, 4.3% iron, and no silver. At the Surprise mine in the valley of the east fork of Pine creek, lead concentrate carries about 58% lead and 16 oz. silver per ton, and the zinc concentrate about 44% zinc and 3 oz. silver per ton. Mr. Ransome states that at the Bear Top mine the ore consists of galena, associated with sphalerite, pyrite, chalcopyrite, and calcite, and that a carload sorted and shipped in 1904 carried 6 oz. silver per ton and 72% lead. I do not have similar specific information about any other mine in the Prichard areas, but I am frequently told, as objections to certain prospects in the Prichard formation, that the ore is very zincy and the silver ratio low. There are a few quartz-

¹¹*Mining and Scientific Press*, June 1, 8, 15, 1912.

¹²Professional Paper 62, U. S. Geol. Surv., 1908.

galena veins free from blende in the Prichard rocks, but far the larger number are of the zinc-bearing type. In fact, until recently, practically all of the zinc production of the Coeur d'Alene district has come from mines in the Prichard formation. There are, in the Pine Creek group, veins in which the ore is almost exclusively blende, galena only occurring in isolated small shoots. It is probable that in time there will be a considerable zinc production from a number of small mines in the Prichard areas.

Relation of Ores to Small Fractures

The ores under discussion are invariably connected with small fissures in the Prichard rocks. The ore-shoots frequently are confined to the places where the fissures cut across quartzite bands. The reason for this is the purely mechanical one that the quartzite fractured better than the slates and gave rise to less gouge, as pointed out by Mr. Ransome. As fissures, they do not materially differ from the fractures with which the ores in higher formations are connected, but in mineralogical composition the Prichard veins contrast rather strongly with the veins in the Burke and Revett formations. Only one mine in the latter makes a zinc product, the Morning mine near Mullan. I am not familiar with this mine, but Mr. Ransome describes the ore as containing galena, sphalerite, pyrite, and a little pyrrhotite in a gangue of siderite, barite, and quartz. The galena is fine grained, much of it of a steel-like texture. The silver ratio is 3 to 4 oz. to 7 to 9% lead. This deposit, therefore, is not of the Prichard type. The nearest approach, mineralogically, that I have found in rocks higher than the Prichard is certain disseminated zinc-lead mineralization in Revett quartzite in the Wardner district, in which the zinc is generally several times as abundant as the lead, and the silver ratio is very low. The mode of occurrence, however, is quite different from the Prichard type. It is beyond question that this type is strictly confined to the Prichard formation. In this formation it is widely distributed, not in one continuous area, but in separate areas on opposite sides of the great mining districts whose ores are found in the Burke and Revett quartzites. There is an important group east of Murray,¹³ another west of Sunset Peak, and a third in the Pine Creek basin. The type is also represented in the extensive Prichard area on both sides of the south fork of the Coeur d'Alene river near Kellogg and in Moon Creek basin. It is, furthermore, widely distributed in Prichard areas beyond the Coeur d'Alene district, in northern Idaho and western Montana nearly to British Columbia.

Mines and Prospects

There are comparatively few producing mines, but small prospects are numerous. In the Burke and Revett quartzites, the ores are in larger deposits connected with a much smaller number of fissures. There are, in the Coeur d'Alene district, no mines and relatively few prospects in the St. Regis forma-

tion. In the Wallace there is one mine, the Gold Hunter, near Mullan, but extensive areas of the formation are without traces of lead or zinc prospects. In this respect, the Wallace contrasts strongly with the Prichard, although both formations contain argillites. There is nothing in the structure to explain this contrast. It leads me to the conviction that the Prichard is much nearer, stratigraphically, to the source of the minerals than is the Wallace. The many small deposits in the Prichard suggest that they constitute the roots of the vein system, that they combine upward into fewer and larger veins in the Burke and Revett quartzites, and that few of these veins survived as high as the Wallace formation. This is purely figurative, but conveys the idea that the Prichard has been the source of the lead, zinc, and silver in the entire vein system.

The Prichard type of mineralization is not controlled by altitude. It ranges from less than 2300 ft. near Kellogg to about 3500 ft. at the Surprise mine, 4400 ft. at the Monarch mine, 4900 ft. at the Terrible Edith mine, and 5100 ft. at the Bear Top mine. Other types of ore mineralization in the district are known to range from about 1600 ft. in the Bunker Hill & Sullivan mine to 5250 ft. at the Standard-Mammoth mine, 5750 ft. at the Morning mine, and over 6000 ft. at the Hercules mine.

Types of Mineralization

In my Wardner paper, already cited, I have described 75 faults distributed among nine systems and have discriminated 12 'types' of mineralization. I do not recognize any important mineralization as connected with the first, third, fifth, and sixth systems. I find first a disseminated siderite of an early but rather indefinite age. After that I place some deposits that may be of a contact metamorphic character. The first zinc-lead mineralization is a dissemination in quartzite and is considered older than the second fault system. It reaches an altitude of 4000 ft., but has not been much explored underground. The Sullivan disseminated pyrite and Phil Sheridan siderite and pyrite are connected with the second system of faults. The Blue Bird, Buckeye, and Ontario types represent a single stage of ore deposition connected with the fourth fault system. The Jersey type is connected with the seventh system. The Alhambra and Bunker Hill types represent a third important stage of ore deposition due to the eighth fault system. Finally I connect the Jackass type with the ninth system. I have recently learned that there is, locally associated with another of the great faults of the ninth system, an ore consisting of quartz, galena, sphalerite, pyrite, and calcite. The presence of considerable calcite and the tendency to develop much pyromorphite in the zone of oxidation, set this deposit apart, mineralogically, from all others in the Wardner district, though there are some features about it that lead me to place it tentatively in the Jackass type. These various types are clearly distributed without any reference to altitude, and as they all occur in quartzites, they show little change due to rock formation. Their differences are mainly due to their having been deposited at different periods

¹³See map accompanying Prof. Paper 62, U. S. Geol. Survey.

of time when conditions of heat, pressure, and source of material differed. The point I am trying to make is that in the Coeur d'Alene district, a range of altitude of 3000 or 4000 ft. has scarcely any noticeable effect on the character of the deposits except such as may be traced to the influence of different formations. The Prichard type owes its characteristics solely to its environment.

Distribution of Zinc-Lead Deposits

There is a very unequal distribution of zinc-lead deposits in the Prichard formation. Practically all the mines and the vast majority of prospects occur in the upper portion of the formation. The deposits that may be said to have some promise are generally distributed near the borders of the large Prichard areas, though the zone of prospects extends farther in, while the central portions of the areas are notably barren. It appears in the Coeur d'Alene district that these deeper portions of the formation are characterized by gold and copper prospects rather than lead and zinc. I refer particularly to the Murray region and to the Elk Creek district near Kellogg. It may, however, be a fact with no genetic significance. But if one spends much time examining prospects and mines in northern Idaho and western Montana, the conviction will grow in his mind that if he finds in Prichard areas a deposit of any promise, it is almost certain to be in the upper 1000 ft. of the formation. This leads me to think that the minerals, if diffused in the Prichard, were largely confined to the upper portion of the formation.

Relations of the Deposits to Faults

The question will be asked why the known ore deposits are absent from large areas of the Coeur d'Alene and neighboring regions, if derived from diffused mineralization in the sediments. My reply to this is that in the large areas free from prospects, the strata almost invariably will be found at low angles of dip. The mineral belt of the Coeur d'Alene is a comparatively narrow zone that has been excessively faulted. The same formations in broad belts to the north and south lie at similar altitudes, but relatively undisturbed attitudes. Take the United States Geological Survey map of the district and note the dips near the mines, as follows: Bear Top, 75 to 90°; Paragon, 75°; Monarch, 60°; Tiger-Poorman, 65°; Standard-Mammoth, 72°; Helena-Frisco, 80°; Black Bear, 80°; Morning, 75°; and Gold Hunter, 80°. At the Terrible Edith, the strata dip 45°, near the Surprise about 55°, at the California mine 50°, and at the Granite mine 55°. There appear to be some exceptions, such as the Hercules, Sunset, and Sixteen-to-One mines, where the strata are relatively flat. In the Wardner district most of the orebodies are associated with faults that dip southerly and with a system of cross-fissures. I have noted that the latter are practically confined to those blocks in which the Prichard slate lies deep, in other words, in those blocks in which the strata dip southerly at angles which enable the Revett or Burke quartzites to penetrate deep within the block. The other ore deposits bear

a similar relation to the structure. In blocks whose strata dip north there are scarcely any commercial deposits. I interpret these facts as meaning that if the minerals were disseminated in the Prichard formation, in order that they should be sufficiently concentrated to make commercial orebodies or even merely prospects that might attract attention, it was necessary that the rock be tilted at a considerable angle so that ascending solutions would be in contact with the diffused mineral for a considerable depth; in other words, it was necessary to leach a large mass of rock to make an orebody. The northwestern quarter of the Coeur d'Alene district as mapped is practically free from lead and zinc prospects, because the strata, although considerably faulted, have relatively low dips. In ascending the North Fork river nearly to The Forks, I found St. Regis, Wallace, and perhaps higher strata lying nearly flat; there are no lead prospects, though at Britt creek there is a quartz vein carrying chalcopyrite. Of course, some of this barrenness may be due to the presence, at the surface, of the higher members of the Belt series, but the same members have lead prospects, where highly disturbed, in the Mullan region. Taking into consideration the probable inequality in the distribution of the supposed diffused mineralization, then the necessity of greatly disturbing and highly tilting the rocks, the further necessity of exposing them to strong ascending currents of water, and finally the fact that many of the deposits evidently did not ascend much above the Prichard formation, it is not surprising that the mines and prospects are highly localized. I will rest the case for the sedimentary hypothesis.

Missouri has by far the most important and extensive barytes mining districts in the United States. In 1912, according to statistics compiled by H. A. Buehler, the state geologist, this state produced 24,530 tons of barytes, valued at \$117,035. This is 65% of the production in the United States, which totaled 37,478 tons. Missouri ores were valued at \$4.77 per ton, while those of other states varied from \$2.34 to \$2.99. The larger deposits of barytes in Missouri occur in the residual clay overlying the solid-rock formation. These deposits sometimes overlie fissure veins in the limestone which carry barytes and galena. The old Virginia mines in Franklin county were worked to a depth of 500 ft. for lead ore, the gangue mineral being barytes. The Enterprise mine, near St. Clair, is opening a fissure containing both barytes and galena.

The Montana Power Co. has spent over \$100,000 at Thompson Falls this summer in the erection of comfortable buildings for the accommodation of 600 men to be employed in the construction of the dam at Clarksfork river, where a large power-plant is to be erected.

The Sulphide Corporation, Broken Hill, milled 26,496 tons of ore during the six weeks ended June 28, yielding 4472 tons of lead and 7961 tons of zinc concentrate. The Cockle Creek smelter produced 1659 tons of lead, 5019 oz. gold, and 163,883 oz. silver.

Resoiling After Dredging

Considerable attention has been paid to resoiling in Victoria, Australia, and the following notes are from the government report on dredging for 1912.

At the Collegian dredge, working at Dry creek, near Bonnie Doon, the appliance in use for replacing the soil is a shoot made of sheet iron $\frac{1}{2}$ in. thick. Advance stripping operations are systematically carried on, and earthy matter, intermixed with some gravel, is being replaced on the dredged ground to an average depth of 18 in. Sand shoots are also used, but for the most part the gravel and sand are covered with the replaced overburden. Owing to varying depths to rock bottom the surface of the re-deposited material is rather uneven. The total area thus dealt with to date is about 16 acres.

The Briseis No. 2 plant is the most up-to-date for resoiling on Yackandandah creek. The soil conveyor deposits an average depth of $4\frac{1}{2}$ ft. of overburden, which is eventually leveled off. The area treated is 18 acres.

The soil shoot at the Harrington plant is about 95 ft. long, 48 in. wide, and 21 in. deep, made after the pattern of that on the Collegian dredge. The upper 20 ft. in length has a pitch of 3 in. to the foot, the remainder having about $1\frac{1}{4}$ in. per foot. This appliance is systematically used, and good work is being done in the way of resoiling. Earthy overburden to an average depth of $3\frac{1}{2}$ ft. is being put back, on a fairly even grade. In September 1912 about 6 acres of the resoiled area had been plowed, and to a great extent leveled. According to the inspector's report, this ground looked well. It was intended to plow the rest of the treated ground when it became firm enough to support the weight of horses. Total area resoiled at that date was about 12 acres.

The Porepunkah dredge has operated in a difficult position, but has resoiled 12 acres in patches. Good results are being obtained at Hinnomunjie No. 1 plant, working on Livingstone creek, a few miles downstream from Omeo. In this case the ordinary wooden sluice box is utilized to conduct the soil from the buckets to the dump, but an additional length of 30 ft. is brought into use when advance stripping of the overburden is in progress. This admits of the earthy material being deposited well back from the face of the dump, and there retained on top of the gravelly wash, in place of being sluiced back into the operating pond at the stern of the dredge, which would otherwise necessarily occur owing to the large quantity of water required to force the material along the comparatively flat slope of an ordinary sluice-box. The ground being treated in this locality was originally a low-lying marshy area of good black soil. As a result of the early mining operations conducted upstream more than 50 years ago, the surface of the flat is covered by mining debris to depths of 3 to 4 ft. Owing to the tenacity of the clayey-black soil, and to the fact that much of it is matted and held together with roots of former vegetation of the swamp, good results are being obtained in the way of resoiling, as this black soil brought up from below the old mining debris is deposited in a

2 to 4-ft. layer on top of the coarse tailing in large solid lumps, practically unchanged from its virgin state. After reasonable exposure to atmospheric action and weathering, this ground will be in a more useful condition than it has been for more than fifty years. About 32 acres of resoiling has been done at this place.

The Myrtle Queen dredge has treated 7 acres of ground. A heavy screw is worked in a chute, which churns the soil into soft mud and is easily deposited. The resoiled area of the Buffalo Star Dredging Co., Lower Buckland, yielded a crop of oats averaging 4 ft. high, and when cut into chaff the yield was more than 2 tons per acre, and the estimate of grain was 60 bushels per acre. The Confidence dredge on the Ovens river has resoiled 20 acres.

Iridosmine From New Randfontein Mine

By C. BARING HORWOOD

This mineral, which has been found in several South African gold mines, is an alloy or intimate mixture of iridosmine and osmium, generally with some ruthenium. It was collected from battery concentrate, black sand residue, and die sand, where, because of its high specific gravity, it was with difficulty separated from the gold. The amounts found were too small for it to be of other than scientific interest. A quantitative analysis of concentrate, after removing the Hg used in amalgamating, gave Au 1.24, Pt 0.61, Fe (as Fe_2O_3) 1.29, Ni (as NiO) 0.66, and osmiridium, 95.52, the last containing about 45% of iridosmine, which indicated that the mineral was essentially iridosmine. Part of the iron was in the free state and probably came from the stamps used in crushing the ore. The iridosmine and associated metals have not been recognized underground nor in hand specimens. They are associated with gold and pyrite, and they seem most likely to occur in that auriferous banket reef known as Carbon Leader, which is distinguished by the abundance of carbon, and further they carry nickel. These metals are of secondary origin and occur in minute amounts as primary segregations formed by magmatic concentration in basic eruptives. By the last or pneumatolytic phase of eruptive activity they were extruded from the dikes by superheated gases. Later hydrothermal action probably played an important part in concentrating them in the banket reefs.—*Chemical News*.

Gold and silver production of the Auckland province, New Zealand, during the first half of 1913 totaled \$2,092,000, a decrease of \$153,000 compared with the same period in 1912. The producing districts during July were Ohinemuri, \$336,000, Thames, \$18,200, and Coromandel, \$7700. The principal producers during the month were.

	Tons.	Yield.
Waihi	14,568	\$120,000
Talisman	3,850	96,000
Grand Junction	9,096	83,000
Waihi-Paeroa	13,400*	24,000
Crown	1,227	13,000

*Tube-mill plant treating tailing from Ohinemuri river, 6 to 15 miles from the above mines.

The Nitrate Fields of Chile

By WALTER S. TOWER

*The importance of Chilean nitrate depends on a curious whim of nature. Nitrogen is needed by all plants and animals, and though the atmosphere is nearly four-fifths nitrogen, few plants and no animals can draw directly on that universal supply. Animals secure their nitrogen through the medium of plants, and most plants must get it from the soil. Some cultivated crops rapidly use up the soil nitrogen, and in such cases the easiest way to maintain productivity is by applying fertilizers. Nitrogenous fertilizers once were made largely from guano, fish scrap, slaughter-house refuse, etc., but their

easy to get at, for it lies on or near the surface. In some places, the caliche is covered with 25 or 30 ft. of fine dust (*chuca*) and coarser rock waste (*costra*) which must be thrown aside by the miner. In such places, an area which has been worked looks as though it had been badly furrowed by gigantic ploughshares. In other places, there is almost no overlying material to remove. The layer of caliche may be as much as six feet thick, but for the most part it varies between one and three feet. The beds in some parts are fairly continuous over large areas; in others they are of limited ex-

WORKING CALICHE DEPOSITS.

manufacture now depends mainly on natural nitrates. These occur in many parts of the world, but they have been found in large amounts only in the northern provinces of Chile.

For Chile itself no other thing has been more important than nitrate in affecting national progress. Nitrate has led to costly wars which established the prestige of Chile as the leading nation on the west coast of South America.

Chile Saltpetre

Chile saltpetre, nitrate, or *salitre* as it is called, is when pure a glistening white compound, salty and bitter to the taste, like some sea plants, and capable of absorbing a great amount of moisture. Chemically the substance is sodium nitrate (NaNO_3). Pure nitrate is found only in small quantities or 'pockets.' Commonly it is mixed with earthy materials and various saline compounds, as common salt, Glauber's salt, and borax. A small amount of iodine compounds also is present in most cases. This impure raw material is known as *caliche* to the nitrate miner.

Caliche, unlike many raw forms of minerals, is

tent. Some caliche contains more than 70% of nitrate, but 50 to 60% is considered high; the average is nearer 20 to 30%, and even as low as 15% is worked profitably. Hence the conditions of production, costs of operation, and profits to be made vary widely from place to place. With few exceptions, however, it is true that the costs of operation are low as compared with many other mining industries, while the profits are large.

Situation of Nitrate Deposits

The main nitrate fields lie in two provinces, Tarapacá and Antofagasta, between latitudes 19° S. and 27° S. Other deposits doubtless will be found farther south in Atacama, and there are said to be small nitrate areas in Tacna, the most northerly province of Chile. The total area of these four provinces (105,000 square miles) is about equal to that of Colorado, and its population (316,000) gives about two per square mile.

The nitrate beds lie in a belt, commonly less than ten miles wide, about 500 miles long north and south, and 15 to 100 or more miles back from the coast. This short distance from the coast is important in making shipment cheap. Between the Coast moun-

*Abstract from *The Popular Science Monthly*.

tains and the base of the towering Andes lies lower land, known as the *pampa*, which slopes westward from the Andes to the Coast ranges. The nitrate deposits lie along the western side of the pampa, its lowest part, associated with what were once the bottoms of water-filled basins, either lakes or arms of the sea. Lines of flats, covered with dazzling white salt beds, or *salares*, extend over many square miles. The presence of nitrate is easily determined. In a manner much like that of using flint and steel on tinder, particles of any supposed caliche are brought in contact with a strip of burning cotton wicking, or *mecha*. If nitrate is present, the particles ignite sharply, and with no further test an expert can tell approximately the percentage of nitrate present.

Solubility of Nitrates

The nitrate is so readily soluble that the deposits could not exist even in a moderately rainy region, but there is little trouble on that score in northern Chile. The high Andes on one side and the cold Humboldt or Peruvian current on the other make Chile north of the 30th parallel one of the driest regions in the world. Some places have passed more than a decade without a drop of rain. If absolute desert exists in the world, it lies in the nitrate pampa.

In crossing this region one cannot help feeling the utter helplessness of man in the face of such great expanses of waterless and lifeless wastes. All directions lead to sand, more sand, even to the border of the ocean itself. One fails at first to understand how men are willing to live there year after year; why those who go away generally come back again to this apparently limitless desolation. But almost the first day's stay reveals part of the reason. The day is not unpleasant despite the heat and the intensity of the sunlight, for the extreme dryness makes temperatures of 90° or more quite comfortable, and the colors—the grays, yellows, violet—playing over the sands, help make up for the lack of living green. The nights are wonderful—cool, crisp, refreshing, with the brilliancy of sky that only deserts can have; while the moonlight gleaming from millions of salt crystals lights up the land with an effect of half day and renders into attractive forms the most prosaic objects.

Presumably dryness also was a factor in the formation of the nitrate beds. It seems certain from the kinds of rocks found there that the area between the Coast ranges and the Andes once was occupied by a bay or long arm of the sea. Then the land began to rise, cutting off the bay and converting it into a lagoon, entered perhaps by every high tide. About its borders great flocks of birds congregated—as they do now along the neighboring coast—to feed on the prolific life in the shallow, warm waters. Enormous deposits of bird guano accumulated about its shores as the years went on. Meanwhile, however, the land was rising higher and higher, water came into the lagoon only from the land, bringing with it soluble nitrates from the guano. But this supply of water was too small to keep up the level; and as the region became drier

and drier, evaporation reduced the original sea to a string of lakes occupying isolated basins in the lower parts of the pampa. As evaporation went on, these waters became too salty for life to endure. With their food supply gone, the birds were forced to seek other haunts, and the accumulation of guano stopped. Streams and occasional rains, perhaps more frequent then than now, washing away the guano, brought together in the lakes compounds of nitrogen and soda, and the formation of nitrate of soda was the result. Eventually these waters became saturated with the different salty compounds, and as evaporation still continued, the different salts began to deposit on the pampa, in the salitreras and salares, much as they are today. Then as a final step, sand and rock fragments from neighboring hills covered the beds with their present capping of loose waste.

Other explanations of the origin of the nitrate have been advanced. One ascribes it to natural chemical processes accompanying decomposition of different minerals. Another suggests that the wonderful electrical discharges in the Andes are responsible, for the odor of nitric acid in the air is not uncommon after severe electrical storms, and electricity even now is being used to extract nitrogen from the air. But the enormous amounts of nitrate in Chile and the geological conditions of its occurrence fit in best with the idea of origin from guano, as stated above.

History of the Industry

Prior to the nineteenth century the outside world knew little or nothing of these nitrates. Fertilizers were then quite unheard of in most places; industrial uses of nitric acid and its compounds were few; and for making explosives—then gunpowder was the only one—small, scattered deposits of true saltpetre provided the raw material.

About 1826, a Frenchman is credited with having established the first real nitrate works in the pampa back of Iquique. A little more than 8300 tons of nitrate is said to have been exported in 1830.

The nitrate fields then were divided among three countries. Peru owned Tacna and Tarapacá. Bolivia owned most of what is now Antofagasta, while Chile owned from Atacama southward. This last region was then not known to contain nitrate, and still is the least important part of the fields. Peruvians and Chileans became most active in the industry, perhaps because the fields were more easily reached from Peru and Chile than from the highlands of Bolivia. Important concessions were granted by Bolivia to Chilean interests, and in 1874, in return for the cancellation of a debt owed Chile, Bolivia agreed not to impose any export tax on nitrate for twenty-five years. Four years later, however, attempts were made to levy a tax of ten cents per 100 pounds on all nitrate exported. When the Chilean companies refused to pay the tax, the Bolivian authorities seized their property and declared that it would be sold. Chile then undertook to protect the interests of her citizens. Since Bolivia had entered some years earlier into a treaty with Peru against Chile, Peru also was dragged into

the quarrel, the result of which was the beginning of war by Chile against both Peru and Bolivia in 1879. The treaty of peace, signed in 1883, found Bolivia driven out of her seacoast province, Peru deprived of her nitrate lands, and the Chilean boundary pushed more than 400 miles northward. It was predicted then that possession of the nitrate lands would ruin Chile, as guano and nitrate were believed to have ruined Peru, but this gloomy forecast has not been verified.

Recent Progress

Since the war, and especially in the last fifteen years, a number of things have led to great progress in the nitrate industry. Foreign capital, English, German, Belgian, French, Austrian, and some from this country, has been added to the large in-

in 1911 the exports were but little short of two and a half million tons. To take care of this greatly increased demand, plant after plant has been built, until now more than 100 are in operation, several of which can produce in a month more than the whole exportation amounted to in 1830. With all this enormous growth and prosperity, the process of production still is almost as simple as when the industry began. The first step is to make a hole about six to ten inches in diameter through the layer of caliche. The bottom of the hole is enlarged so that a charge of powder may be put under the caliche. Most of the powder is made locally from nitrate, charcoal, or coal dust and sulphur, for here it is so dry that the nitrate cannot absorb enough water to make it unfit for powder. The explosion of the charge heaves up the caliche,

INTERIOR OF NITRATE WORKS, SHOWING BOILING TANKS.

vestments made by Chileans. Thus more than £20,000,000 of English capital alone is tied up in this business. Methods of manufacture have been improved, and the scale of operations has been increased greatly. New railroads have been built and old ones extended, until now there are about 2000 miles of railroads, most of which have no other use than to serve the nitrate trade. But perhaps most important of all has been the vigorous campaign to advertise the merits of nitrate as a fertilizer.

Nitrate Exports

The exports of nitrates in 1830 are said to have been about 8300 tons. At the time of the Peruvian war, fifty years later, the amount had increased to 226,000 tons yearly—or less than the amount that two establishments might turn out now. Since 1880 the exports have reached enormous proportions. The million-ton mark was passed in 1890; almost a million and a half tons was shipped in 1900; and

commonly in blocks which must be broken into smaller pieces with a heavy hammer. This is the process of nitrate mining. No operation could be simpler.

Labor in the Nitrate Fields

If the miner works by the day, he is known as a *barretero*, literally a 'crowbar man.' If he is paid according to the amount of caliche mined, as the most energetic prefer to do, he is a *particular*, or private worker. The former earns about ₧6 to ₧7 per day, while the latter, under favorable conditions, often makes ₧9 to ₧12 per day. A group of *particulares*, working early and late, quickly dispels any idea that no people of that part of the world will work hard.

Carts or trains of small dumping cars carry the caliche to the *maquina*, as the refining plant is called. Here it is first crushed into pieces no larger than a man's fist. From the crushers it goes up inclined planes to the boiling tanks, or *cachuchos* as they are

still known, though earthen pots have been replaced by great iron affairs 32 ft. long, 9 ft. wide, and 8 ft. deep, capable of holding 70 tons. The newest *maquinas* have twenty to thirty of these tanks. When the charge of *caliche* is in, water is added, steam is turned into a coil of pipes which runs around inside the tanks, and the boiling process begins to dissolve the soluble nitrates from the insoluble and worthless earthy substances. Thus the industry, which in one respect owes its existence to absence of water, must have water in order to operate, for nowhere are there large amounts of *caliche* rich enough to ship without refining, and the process of *leaching* is the only economical method of refining.

Fuel

Much Australian and English coal, costing ₧35 to ₧50 or more per ton, is used to generate the steam. About half a million tons of coal has been imported for this purpose in recent years; but the possibility of substituting California petroleum, already used to some extent, is being considered seriously by many operators.

To get water for the *maquinas* is not everywhere easy, for the water-supply always has been the chief problem in this region. The first railroads had trouble getting water for their engines, some resorting to the distillation of salt water; but now for the railroads, and the chief cities and towns, piping of water 100 to 200 miles from the Andine streams has relieved the situation greatly. In the *pampa*, wells yield a good deal of water, commonly more or less salty, but this source cannot be counted on everywhere. Thus in central Antofagasta one plant secures more than 35,000 gal. of water per day from three wells, the deepest of which is less than 100 ft.; but another plant, less than a mile away, found no underground water after spending ₧250,000 in the attempt.

Precipitation of Impurities

After the water in the *eachuchos* has boiled for several hours, it is passed to another tank where it encounters fresh *caliche*, and so on, until a saturated solution known as *caldo*, or broth, eventually is secured. When this point is reached, the water is run off to a series of tanks, known as *chulladores*, where the use of wheat flour, stable manure, or other substances, causes the precipitation of the miscellaneous soluble impurities, except ordinary salt, which have been dissolved out with the nitrate. From this purification process the solution goes to the crystallizing tanks, or *bateas*, which are placed ten or twelve feet above the ground to permit free circulation of air and promote cooling and evaporation. Thus dryness which figures in the origin and preservation of the *caliche*, also has an equally great value in the process of manufacture. As the solution cools and the water evaporates, the nitrate begins to crystallize on the surface, so a 'stirring boy,' or *rayandero*, is employed to break up the film and make it settle. Five or six days is necessary to complete the crystallizing process. A large plant may have 300 or more *bateas*,

capable of holding more than 1,000,000 gal. of *caldo*, and yielding at each full charge as much as 2500 tons of nitrate.

When crystallization has gone as far as it will, a valve in the bottom of the *batea* is opened and the liquid is drawn off, leaving behind a thick layer of glistening white crystals. This is the nitrate, or *salitre*, of commerce, being 95% or more of pure nitrate of soda; the remainder is largely water and salt. The liquid which is drawn off, known as *agua vieja*, or mother liquor, still contains a large amount of nitrate in solution, and is used over and over again in the boiling tanks. In fact, no water is ever thrown away, the only loss being that which passes into steam from the boiling tanks and evaporates from the crystallizing pans. The finished nitrate is shoveled from the *bateas* into cars, and there, after drying for several days, is bagged ready for shipment. Shipment in bulk is impracticable because the nitrate so readily absorbs water. Even when shipped in sacks it sometimes becomes caked in the holds of ships and has to be taken out with picks.

Iodine By-Product

From the mother liquor, iodine is extracted by a simple process of precipitation with chemicals (mainly sodium sulphites). It figures only as an important by-product of the industry, for the 'iodine-trust' makes an annual allotment to each establishment, commonly less than what could be made in a month, if there were no restrictions on production.

The only other important step in the refining of nitrate is the clearing and recharging of the boiling tanks. First, fresh water is run through to take out what it will of the remaining nitrate, this water being used subsequently, with mother liquor, in the boiling process, for the more nitrate in solution at the outset the easier it is to get a saturated *caldo*. After the washing is over, a trap in the bottom of the tank is opened and the waste is removed. This process is the most bothersome in the industry, because for each charge of 70 tons of *caliche*, 50 tons or more of waste must be removed. It is hard on the men who work in the steaming hot tanks, and the disposal of the waste after it is removed, not uncommonly 1000 to 2000 tons per day, soon comes to be a problem. None of the operators succeed in getting much more than 75% of the nitrate originally in the *caliche*, hence the waste commonly contains 4 to 10% of nitrate, and the great piles containing millions of tons of waste some time may be re-worked if conditions in the industry should make economies necessary.

A good deal of capital is needed to start a nitrate business on a large scale. Many of the older *oficinas*, as the establishments are called, are small, representing an investment of not more than ₧25,000 to ₧50,000. But a large modern plant may cost ₧6,000,000 or more. For this reason the industry tends to remain in the hands of companies, about 80 in number, of which a few large ones really dominate the industry. In all, there are about 160 *oficinas* in existence, English, Chilean, Austrian, German, etc., but for one reason or another not all of

them are being operated. Exhaustion of the supply of caliche is the most common reason, for as a general rule an oficina is built for a given tract of nitrate land, with the idea of abandoning it when that supply is exhausted. It does not pay to haul caliche any considerable distance, for a ton of average caliche will yield only about ₡30 worth of nitrate, on which the profits may be ₡10. There are only one or two American companies. United States capital invested in western South America seems to have been attracted more strongly by other kinds of mining.

Production of Modern Plants

A modern plant, like the Aníbal Pinto, in central Antofagasta, running 24 hours at full capacity, may have a daily output of 5000 Spanish quintals (quintal=101 lb.) of nitrate. The cost of production in May 1912 at this plant was stated to be about ₡2.50 per quintal, covering everything up to the time of shipment. To this figure must be added the transportation charges to the vessel in Antofagasta harbor, about ₡1 per quintal, and the export duty of ₡2.50 per quintal, making total costs on board vessel ₡6 per quintal. At that time the selling price, on board ship, was ₡7.50 to ₡8 per quintal. Under favorable conditions, therefore, this oficina could market about 2,000,000 quintals per year, with profits amounting to ₡4,000,000. This particular plant cost more than ₡6,000,000, but with the trade good it would pay for itself in two years and give annual dividends of 10% at the same time.

The construction of a modern plant uses supplies from widely separated places. Most of the buildings are of corrugated iron, for it withstands the intense dryness better than wood does. It commonly comes from Europe. The timber which is used is likely to be Oregon pine, for it is strong, durable, and about as cheap as the Chilean product. German steel for tanks, cement from the United States, boilers from England, Belgian locomotives to haul the tiny cars, and United States electrical equipment are found at one plant.

Most of the laborers are Chileans, Peruvians, and Bolivians, attracted there by the higher wages than are to be had elsewhere in most other pursuits. In fact, the complaint is often made that the nitrate industry has retarded development of other activities in Chile, especially greater agricultural progress in the south, by absorbing not only the capital, but the labor as well. About 40,000 persons are said to be employed directly in the nitrate establishments, some of the larger of which have more than 1000 hands each. Wages run from about ₡3 to ₡4 per day for boys and ₡6 per day for the poorest paid men, up to as high as ₡15 for some of the men working in the mill. Perhaps ₡10 is a fair average for the majority. Houses are provided by the company, but heat, light, and water must be paid for by all except salaried employees.

Though wages and salaries appear high in units of currency, the prices of foodstuffs also are necessarily high, since next to nothing can be raised anywhere in the nitrate region. A good many of the cattle used here come overland from Argentina.

Kerosene from the United States costs about ₡1 per gallon, but the tin in which it comes also must be considered, since it serves a multitude of uses, from waterpail to roofing material and baking oven.

The laborers generally are paid not in money, but in *features*, discs resembling poker chips and bearing the company name, together with the equivalent value in actual currency. These features are used almost solely at the company stores, but if any workman desires his wages in money he may draw at any time all that is due him. Large establishments.

LA DEMOCRACIA WORKS NEAR IQUIQUE.

with their many hands and the families, may make communities of 2000 to 3000 persons. Schools are provided by the government.

Exportation of Nitrate

Ships of many nations come to carry away the nitrate, while many coastwise vessels bring supplies from the fertile valleys farther south. Nearly half the companies operating in 1912 shipped their product through Iquique, giving this port more nitrate traffic than is carried on by any other two ports combined. Antofagasta and Tocopilla are next in order. The value of nitrate exports is more than 70% of the total value of Chilean exports, and its tonnage is as great as that of any other South American export. As the nitrate goes out, the Chilean government levies an export duty, just as Bolivia tried to do when Chile took up arms on that account. The export duty sometimes is regarded as a device for checking overproduction, whereas it is simply an effective means of raising revenue for the national treasury. For a long time nitrate duties and proceeds of sales of nitrate lands have amounted to more than half, and in some years to not less than 85% of the total national income. These revenues alone represent more than \$10 per capita, or as much as the United States Government spends from all sources of income. It is easy to see, therefore, why Chile often is charged with extravagance. Yet large sums have been employed wisely in the building of state railroads; something has been done, and much more is now being undertaken, to improve port facilities, especially at Valparaiso; and much of the money has been used in building up an army and navy to insure Chilean leadership and prestige among the West Coast countries. It is estimated that in the thirty years following 1880 the

total revenue from nitrate duties has been more than \$300,000,000 (U. S. gold), while with the present rate of production and the same tax continued, the next twenty-five years will give Chile nearly \$750,000,000 (U. S. gold) more.

Control of the Production

One check on overproduction may be exerted through a law providing that Government nitrate lands are open to exploitation only after such lands have been disposed of at public auction. But, at the same time, this law has tended to check individual effort in exploring thoroughly the limits of the nitrate deposits. Another check on overproduction has been the nitrate trust, or *Combinacion Salitrera*, an agreement entered into in 1901 by the larger companies, concerning the limitation of annual output and its allotment among the different companies. For a number of years prior to 1909 the trust worked well, but since then, despite all efforts to keep them in line, a good many companies have limited their output only by the maximum capacity of their plants. As an official of one of the largest Chilean companies aptly said: "There is no need for agreements when the demand is so heavy and the prices so good. If the price goes down—well, perhaps agreements can be revived then."

The nitrate business is so vital to the northern provinces of Chile, and even to the whole country as it is now organized, that the future of the industry has been a question of much concern. Some believe that the opening of the Panama canal, with the resulting shortening of voyages from Iquique and Antofagasta to the United States, United Kingdom, and Germany, will stimulate the commerce in nitrate materially, for those three countries now take about 80% of the exports. Optimistic prophets, noting also the increasing popularity of nitrates, forecast a new era of greater prosperity than ever before. The more pessimistic, on the contrary, foresee the speedy exhaustion of the nitrate supplies and a crisis for Chile unless adequate preparation is made for the inevitable readjustment.

Available Supplies

Most estimates of the available supplies of nitrate range between 70,000,000 and 100,000,000 tons, which at the present rate of production would insure the life of the industry for 35 to 40 years. Some estimates, however, place the amount as high as 200,000,000 tons. The totals given are about equally divided between Tarapacá and Taena on the one hand, and Antofagasta and Atacama on the other. Private lands, however, are estimated as covering more than half the total, though it must be remembered that the state lands are less well known. The smaller estimates make little or no allowance for discoveries of new nitrate deposits, which is quite likely to happen, nor do they count on any improvements in processes of manufacture, which readily might prolong by many years the duration of supplies now known. It is also possible that ripio, nitrate-bearing costra, and low-grade caliche, thrown aside in the past, may be worked profitably in the future. Should all these things develop fa-

vorably, the nitrate industry could thrive for a good many decades to come. Otherwise, its span of existence is not likely to extend much beyond the middle of the century, for increased production, which is entirely probable, must hasten the end.

Another possible 'rock' ahead for the business has been found by some people in the production of nitrates from atmospheric nitrogen by an electrical process. Where water power is abundant and cheap, nitrates from this process can be made to compete with the Chilean product. It is being done now in Norway. But for most parts of the world which have large water-power resources, the use of this power will be more valuable for other purposes as long as Chilean nitrates continue to be abundant and reasonably cheap.

Value of the Production

It has been suggested that when the nitrate is exhausted irrigation may turn the pampa into a highly productive farming region. This may be possible for limited areas, but from what is known of the water-supplies available, it seems unsafe to look for any extensive agricultural development. Exhaustion of the nitrate apparently means a general decay of the region unless other mineral resources are discovered and developed. It means for Chile the loss of \$100,000,000 (U. S. gold) in annual exports and \$30,000,000 (U. S. gold) of government revenue. For the world it means turning to some other source of nitrogen for supplies to fertilize its crops. Happily the way already is open for the latter change.

Tin production of 13 mines in northern Nigeria in July amounted to 227.6 tons of concentrate. Some of the companies report slight damage from flooded water, and this has interrupted the working of the hydraulic plants where these are installed. The rainy season has now definitely commenced. Labor supplies are scarce despite the comparatively high rate of 18c. per day paid for native workers. Transport difficulties, of course, still operate, as is only natural in the development of a district which is situated such a long way inland in unsettled country. Even with the extension of the Nigerian railway to the edge of the plateau, many mines are still only to be reached from the terminus by a seven or eight days' walk, all machinery having to be carried on the heads of native *pagan* or *Haussa* bearers.

A new mining ordinance for the encouragement of mining in the Northern Territory, Australia, came into operation on June 26, which provides a reward of \$480 to any prospector who discovers a new mineral field that will support a population of 100 people for one year within a period of five years from date of discovery, and \$4.80 per head for every additional person thus supported, up to \$24,800. Also a reward up to \$480, and a reward claim or area for the discovery of a valuable deposit in a locality where mining operations have practically ceased, or in a new locality where no mining operations have been conducted. This territory is controlled by the Commonwealth Government of Australia.

A Japanese Contemporary

THE
MINERS'
FRIEND.

第
一
號

大正二年五月十五日

We present herewith the title page of the *Miners' Friend*, a modest little paper published by the staff of the Furukawa Mining Co., at Ashio, Japan, and of which copies for the months of June, July, and August are now at hand. For fear that some of our readers may be a bit rusty on the vernacular, we translate as follows: "The Miners' Companion of the Ashio copper mine. Edition number 1. Published on the 15th of May in the second year of the Taisho dynasty."

The paper itself consists of ten pages, all in Japanese, and the table of contents for August includes articles on 'Miners Ethics on the Occasion of the first anniversary of the late Meiji-Emperor'; 'Rules and Regulations of the Ashio Mines'; 'Maxims and Mottoes'; 'Practical Considerations—Catechism on the Acetylene Lamp'; 'Biography of Self-Made Men'; 'Hygienic and Sanitary topics'; 'Current News of the Mines', and a literary column.

A paper published for the employees of a mining company is unusual, although a number of the American railways and larger manufacturing concerns print and circulate excellent little magazines. As a stimulus to *esprit de corps* and as a medium for inculcating the rules and precepts of efficiency, such papers are useful. It is rather characteristic that the Furukawa company, which has led in so many things in Japan, should be the first to occupy this field. To M. Otagawa and his staff we extend our good wishes.

The Role of Pressure in Chemical Reactions

By JOHN JOHNSTON

High pressure has been adduced by geologists as an 'explanation' of many phenomena otherwise not readily accounted for; just as many chemists have attributed actions which they did not understand to colloids or to some catalytic element. There is considerable experimental evidence which, when rightly interpreted, shows that high pressure alone—uniform pressure, especially—is incompetent to produce many of the effects ascribed to it; that its effects have been much over-rated, especially in comparison with those produced by change of temperature. For instance, the influences of temperature and of pressure on solubility of solid substances are such that a pressure measured in thousands of atmospheres is required to equal the effect consequent upon a few degrees change of temperature. In many cases—as, for instance, the system water-silicate at 400 to 450°—the main rôle of pressure is to ensure an appreciable concentration of the volatile component; whether its influence is in such cases subor-

dinate to that of temperature or not depends, of course, upon the stability relations of the various substances involved. Existing knowledge of the domain of high pressures is confined almost entirely to qualitative generalities deducible from theoretical principles; its scope can be increased only by careful quantitative investigation, which, it may be added, is certain to yield valuable results, technical and economic as well as scientific. A recent volume, 'Die Anwendung hoher Drucke bei chemischen Vorgängen und eine Nachbildung des Entstehungsprozesses der Steinkohle,' by Friedrich Bergius, is therefore to be welcomed for the extension of knowledge which it brings as well as for its suggestiveness.

It records work on the equilibrium relations of the system $2\text{CO}_2 \rightleftharpoons 2\text{CO} + \text{O}_2$ at temperatures ranging up to 420°C. and gas pressures up to about 140 atmospheres, and on the effects of water at 300 to 350° and the corresponding pressure on carbon, peat, and cellulose. The main results of these investigations have already been published elsewhere, but the following points are noteworthy: Water at temperatures of 300 to 350° and the corresponding pressure reacts with carbon according to the equation $\text{C} + 2\text{H}_2\text{O} \rightleftharpoons \text{CO}_2 + 2\text{H}_2$, no appreciable amount of carbon monoxide being formed. Under the same conditions it gives, with peat or cellulose, products which closely resemble natural coals, the type of coal produced depending mainly upon the duration of heating. This process goes on to a certain limiting composition only (corresponding to a soft coal); but it was found that the percentage of carbon can be further increased by exposing the product to stress, a fact which tends to show that natural anthracite was formed from a soft coal by the action of the stresses to which any deep-lying bed must have been subject. A rise of temperature of 10° doubles (as usual) the rate of formation of this artificial coal; whence it is calculated that the age of the natural coal beds is of the order of eight million years, an estimate which is no more uncertain than any of the existing estimates of the age of the earth. In conclusion, it may be pointed out that investigations similar in character to those described by Bergius may be counted on to contribute something toward the solution of the still mooted question of the origin of petroleum.—*Jour. Am. Chem. Society.*

Phosphate ranked first in the list of exports from Tunis, northern Africa, during 1912, the aggregate value of the shipments amounting to \$9,216,703 as compared with \$7,427,589 for the preceding year. The principal purchasing countries were France, Italy, England, and Germany. The most important concern engaged in this industry is the Société des Phosphates et du Chemin de Fer de Gafsa. It may be stated in this connection that Tunis is, after the United States, the world's largest producer of phosphates.

A large deposit of cinnabar (sulphide of mercury) has been opened on the Maroni river, near Paramaribo, Dutch Guiana. Transportation and native labor in this district is said to be cheap.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Mining and the Big Exposition

The Editor:

Sir—In 1915 the big exposition will be staged in San Francisco. By the time this bit of news appears in print, it will be getting well along toward the end of 1913, which seems to leave a little more than one year in which to prepare our mining exhibit. Please ask your readers to Fletcherize that word 'our.' Also, let us all stop and consider that one year is not any too long a time in which to prepare a mining exhibit worthy of the state of California in particular, and of the Western states in general. It is ample time if all get busy and work together, but we must be getting right at it.

It is 'our' mining exhibit because it is going to be done by us or it will not be done at all. For purposes of an exhibition, mining differs inherently from manufactures, agriculture, and transportation. There is plenty of incentive to the latter industries to exhibit in order to advertise their products, and the wise ones will all be on hand. There is no competition in selling gold, and the copper or lead produced by any company is so nearly like that of its competitors that no commercial advantage is gained by exhibiting the product. Consequently there is but little commercial incentive to the successful mining companies to exhibit. But the advantages to be gained from advertising our mining resources and thus enlisting money for their further development are none the less real because they are spread fairly evenly over the entire state, and all lines of business prosper when the miners prosper. When a gold mine produces a thousand dollars worth of gold it has done something which enriches the world. The stockholders are not the only ones who profit from it. The money is divided among the workmen, the supply houses, the state, and the stockholders. This is newly created wealth, which was not previously in existence; the world is enriched and no one has had to pay the bill. The money moves from hand to hand, through all lines of trade, and benefits everyone. A merchant who receives part of it from a customer may not stop to consider where it came from, but that does not alter the fact that if the mine had not produced it, the merchant would not have made that particular sale. Clearly, then, it is to the interest of everybody in business in a mining community to help the mining exhibit.

To the mining engineers and to the promoters of real mining, the situation will appeal without argument. To the successful mining companies, and to the individuals on whom fortune has smiled through the mining and oil industries—and there are enough men in California to whom great fortunes have come through these industries to finance

a marvelous exhibition without serious sacrifice—there is presented an opportunity to worthily show their gratitude, and to encourage and assist others to help the world by helping themselves on to success in mining. Mr. Mine Owner, you have made a fortune in your chosen branch of the mineral industry; you are proud of your record, you are proud of yourself—and justly so; also you are proud of the state and of the industry which gave you your untainted money. The privilege of expressing your pride and of advancing the interests of the mining industry is now offered you. Those who helped you earn your fortune have known you for years, and they know what your answer will be—if you will but take five minutes alone and think it over!

Mr. Van Barneveld, who is in charge of the Department of Mines and Metallurgy, says there will be 200,000 sq. ft. of space in the Mining and Metallurgy building available for exhibits. There will also be space outside the building. The Exposition has no funds to spend in securing exhibits to fill this space. What are we going to do about it? The East expects great things of California in the way of a mining exhibit. I was in the East last winter and found everybody planning, or hoping to plan, to come out. There they still think that California means 'gold' (the real estate men have not yet beaten us entirely), and one thing we must show them is a very unusual collection of gold specimens, both nuggets and gold-quartz. A loan collection of such specimens should not be difficult to get together, provided their safe return is absolutely assured. This could be arranged by having their return guaranteed by some insurance company. Meanwhile it is worth while for everyone to make note of all good specimens that he sees, with the name of owner and a description.

A big exhibit of gold specimens seems to be demanded of us. Aside from this, Mr. Van Barneveld has already outlined what he wants to accomplish in the exhibit. But when are we going to get started? What has become of the California Miners' Association? Is it slumbering, or is it hiding its light under an ore sack? At its San Francisco meeting last December, a committee on Panama-Pacific International Exposition was appointed. The committee duly met; some one offered a resolution extending the cooperation of the Association to the Exposition officials in securing a suitable mining exhibit; the resolution passed the committee, passed on the floor of the Association, and the committee passed out! (At least so far as one member of it is informed.) "The mountain labored and brought forth a mouse."

We must have \$200,000 or \$300,000 for that mining exhibit, and as much more in work and ability to execute. This is not a San Francisco matter; it is not a California matter. It is a matter for the mining industry of the Western states, with a cordial invitation to the steel and the coal industry, and to foreign countries to join us. The money involved is ridiculously small as compared to the fortunes recently won from the oilfields, from alkalis of the desert, from Goldfield, from Tonopah,

from Bisbee, from Butte, from Jerome, from Alaska, and from less important districts. We should show mining as it is, in actual operation. We want models of mines, models of stopes, quartz mills in operation; certainly we need a gold dredge, an oil well in operation, as well as models of oil refineries. The money involved is considerable, but this is California! Let's get started. We are waiting for the San Francisco mining men to call a meeting and start things, so that we can join them.

J. NELSON NEVIUS.

Pasadena, California, September 16.

Universal Safety Signs

The Editor:

Sir—I submit herewith a design for a universal safety first sign, and would be glad to know your opinion as to the value of such a sign and of the particular design submitted.

If agreement can be reached as to a standard, a manufacturer would be justified in getting out cuts and stock signs in such large quantities as would make the cost much less than if each got out his own designs and printing.

J. W. STONEHOUSE.

Denver, Colorado, August 23.

[The desirability of uniform conventional signs for use in mines and works in marking danger points is beyond doubt, and the movement is one that deserves every support. Miners form a roving class and constantly learning new signals, rules, and signs leads to confusion and is productive of accidents. The value of a danger signal is increased in proportion as it produces an automatic action on the part of the one who is warned by it. Men do not run into danger when they are thinking of it, but when they are not. It is the universal experience that most accidents occur because some one's wits are wool-gathering. To be effective, a danger signal should suggest just one thing to the one to be warned. It should always make the same suggestion, and the latter should come so promptly and regularly that the man will unconsciously heed the signal. It is evident that this cannot be accomplished if different signs are used, especially if a sign or signal at one mine or in one plant means danger and at another safety. There should be some standard, so that a workman in a new situation will find the danger signals in accord with his acquired mental instincts rather than in discord. The value of a red light is greater than a green one in marking danger spots, because of widespread custom, and it is distinctly worth while to attempt to develop a whole system that will in the same way have universal meaning.

Some years ago the geologists found that because of language difficulties and lack of standards in cartography, the maps made in one country were not intelligible in another. The International Congress of Geologists worked at the problem and evolved a color scheme that is now widely used. As a result, an English or American geologist can

read a Russian or Japanese map as well as one made in his own country. In view of the confusion of tongues underground in a modern mine, it would seem that mine managers might well take a hint from what has been accomplished by the geologists. The United States Bureau of Mines, the American Institute of Mine Inspectors, the American Mine Safety Association, and other organizations would do well to attack the problem in earnest. —EDITOR.]

Inclined Baffles

The Editor:

Sir—In your issue of August 2, John E. Rothwell writes under the head of 'Inclined Baffles,' to which I should like to add a few observations. There can be little doubt that inclined baffles greatly accelerate the settling of a dense slime, forming a channel for the rising of the clear solution on the under side of the baffle and a corresponding one for the downward movement of the solids on the upper side of the baffle. The inclined baffle has been successfully applied for this purpose in the Kyloe settler in Australia for concentration work where great capacity within a small area was desired and where a cloudy overflow was not detrimental.

If the first rapid settling is to be continued until a clear overflow is obtainable, the principles involved in the settling change completely. The particles are then far apart and each is free to settle so far as any interference from its fellows is concerned. Time and a quiet settling medium would seem to be the requisites for this kind of settling. Baffles are, I believe, a disadvantage in this kind of settling, as they tend to form currents by restricting the free flow of water, and they also form places of lodgment for the extremely fine material.

As the baffle is strictly a mechanical, or physical, device, I have purposely ignored chemical and electrical theories of slime settlement. Mechanically considered, I believe that the ability of a particle to settle in a cloudy solution is limited only by its infinitesimally small weight and by the viscosity of the settling medium.

Waxhaw, North Carolina, August 10.

Simple Smelting in Arizona

The Editor:

Sir—I really feel that general attention should be called to a new smelting device that has been invented in Arizona by a 'distinguished Eastern metallurgist,' whose only regret is, that he never saw our great state before. The new device is extremely cheap and simple and is bound to revolutionize mining and smelting in this state, and others situated as fortunately. Here it is: "Mix ore and a small amount of coke (charcoal will do where the mines are hidden in thriving forest reserves), expose the mixture to the sun for three consecutive days, and dig the metal out of the ground at whatever depth the coolness of the ground is sufficient to allow it to solidify." Patents are pending. Any infringements will be prosecuted!

TORONTO, CANADA

DOME LAKE FINANCES.—REA, CORALT-FRONTENAC, AND MANN MINES.—CAPITAL FOR BRITISH COLUMBIA PROPERTIES.

Dome Lake shareholders, on receiving a financial statement showing the indebtedness of the Company to be \$61,000, have agreed to the plan proposed by the directors for financing the Company. The General Asset, Ltd., will receive 45,000 shares at par in payment of a debt of \$41,000, and 100,000 shares are to be disposed of at 35c. each to raise the funds to settle other liabilities and proceed with development. The Rea Leasing Co., which is operating the Rea property, has been treating the ore from the dump in the 5-stamp mill, and the result has been so satisfactory that an addition of five more stamps has been decided upon.

BUFFALO MINE, CORALT.

A winze is being sunk on the vein below the 200-ft. level and stoping is being done at that depth.

At the Coralt-Frontenac, in the Elk Lake district, two orebodies giving good assays in gold and also containing platinum have been found on each side of the shaft at the 100-ft. level. They are stated to be 14 and 36 ft. wide. The shaft is being sunk to the 200-ft. level. The Mann, in the Gowganda district, has three cars of high-grade ore ready for shipment as soon as the winter roads are found.

Hugh Sutherland, of Toronto, and a syndicate of British capitalists, including Sir James Sievwright, the Earl of Denbigh, and Major Frank Johnson, have gone to inspect a copper property on Vancouver island, B. C., in which they have invested \$1,000,000, and which promises to become an important enterprise.

JOHANNESBURG, TRANSVAAL

RESULTS OF LABOR TROUBLES AND GOLD PRODUCTION.—UNDERGROUND CONDITIONS ON THE RAND.—FUTURE OF RAND MINING.

The Rand Gold mines have passed through the aftermath of the strike, but although it only lasted a few days, the disorganization, extra expense, and loss of profits were larger than expected. Work on the mines continues somewhat disorganized, although operations were resumed over a month ago largely due to time-expired natives imitating their white masters and refusing to renew their engagements except at exorbitant rates of pay. The mines are gradually, therefore, becoming short of unskilled labor, white men in consequence are being discharged and are reaping in an unexpected manner the results brought about by their own action in bringing about the strike. The disorganization will take many months to overcome, as the Government has temporarily put a stop to recruiting natives, which has added somewhat to the difficulties experienced at the mines. In loss of profits and extra expenses incurred during the strike, the figures for July show a direct loss of about £250,000.

The decreased gold output for the month of July, as declared by the Transvaal Chamber of Mines, was 91,160 oz., value £387,223, and for the first time this year the total

gold output for the Transvaal fell materially below three million sterling, namely, £2,783,917. This was the case, despite the fact that the number of stamps dropping during July was 115 in excess of those at work in June, an increase largely due to a resumption of work at the New Kleinfontein mine. Next to the colored labor trouble on the Rand, the underground health conditions are attracting most attention, and all kinds of proposals are being made with the idea of dealing with the dust evil. One proposal is to adopt firing shots by electricity so as to avoid the fume and dust bothering the miners. From what is being said by the Rand press, mining and otherwise, one would almost conclude that the idea of firing shots by electricity is quite a new and novel idea. As a matter of fact, it was used long before the Rand was discovered, and as far back as thirty-five years it was largely used for shaft-sinking purposes in many mining fields of the world. So firm a grasp on some of the mine managers has this idea of electric firing underground obtained, that it is seriously proposed to withdraw all the men from underground at the time of blasting, and fire the shots from the surface. It has been recognized that the concussion caused by blasting underground largely contributes to the dissemination of the finer particles of dust difficult to be caught by respirators and to which miners' phthisis is now admitted to be largely due. That the underground health conditions of Rand mines have been materially changed for the better, by the more general use of water sprays and introduction of artificial ventilation, goes without saying; but in this direction there is still considerable room for improvement. Some interest has also been aroused locally by the announcement that W. C. Gorgas, chief health officer for the Panama Canal zone, has been engaged by the Transvaal Chamber of Mines to inspect and report upon the health conditions prevailing on the Rand mines in the hope that he will be able to suggest some solution to the difficult health problems still unsolved on the Witwatersrand goldfields.

In the July issue of *The Mining Magazine*, London, appears an article from G. A. Troye on the future of Rand mining, dealing particularly with the prospects of different individual mines which it may be pointed out have not been dealt with in an over-sanguine manner. Few will, for instance, agree with treating the West Rand Consolidated Mines as negligible in the matter of future profits, as with an increased scale of working, this particular group of mines possesses a promising future. Even the Roodepoort Main Reef cannot be dealt with in an off-hand manner, considering the manner in which the mine is opening. Out of the nine mines indicated as doubtful dividend payers, at least six are expected to return something to the shareholders. In dealing with the future of the Rand, the possibilities of the Far Eastern Rand does not receive adequate credit, but perhaps the method of handling the prospects of the East Rand Proprietary Mines will attract most attention. Mr. Troye is evidently of the opinion that the East Rand Proprietary Mines will cease as a dividend payer in five years when the outcrop properties are exhausted. That the Hercules and Angelo Deep properties have proved disappointing is well known, but Mr. Troye has evidently overlooked the promising prospects of the ground lying west of the water dike, as well as the improved deep level and below the Hercules and Angelo Deep properties. Nor can it be said that the Crown Mines have been dealt with in an equitable manner in fixing the life at thirty years, as most engineers are of the opinion that the Crown Mines will last almost as long as mining operations will be successfully conducted on the Rand. At all events, Mr. Troye's estimate of the future of the Rand may be regarded as useful if taken as an indication of what is clearly the least optimistic estimate made on careful lines of the Rand's future in recent times. That Mr. Troye has given considerable attention to the subject is self-evident, and most authorities will agree that, while the gold output of the Rand will for years continue to increase, the resulting dividends in the future will not show a proportionate increase, in fact, it is the general opinion that unless something unforeseen happens, future dividends will not be materially increased beyond their present total.

LONDON

THE ROYAL SCHOOL OF MINES AND ITS STAFF.—CARN BREA & TINCROFT AFFAIRS.—DEVELOPMENT WORK IN THE DOLCOATH MINE.

From time to time during the past few years I have referred to the difficulties of the Royal School of Mines in connection with the appointments to the professional staff. Four years ago the governing body upset the arrangements by unwarrantably falling foul of William Gowland, one of the professors, who had done excellent service in the metallurgical department, and calling for his resignation under the age limit, which is customary in connection with most of the English public appointments. He was succeeded by W. A. Carlyle, who only held the position for three years or so, and then retired. Without reflecting in any way on Mr. Carlyle, it seems to me that the incumbents of professional positions should consider them as permanencies, and in fact their life's work. It is difficult to pick a good professor, and difficult for him to train himself to the requirements; so it seems a pity that Mr. Carlyle should have decided to go back to private practice. The appointment of a successor to him caused more trouble than your readers would have anticipated. More than one possible applicant was deterred from applying for the position, or even allowing his name to be mentioned, knowing that for personal reasons he was *hors de combat*. Eventually an appointment was made that promises to prove successful. H. C. H. Carpenter, the professor of metallurgy in the Manchester University, has been selected. As he is chiefly conversant with iron and steel, and with the physics and metallography of the non-ferrous metals, he has been given two years of what might be called 'half time' before he assumes the full professorship, and in the meantime he is to travel the world studying the methods of extracting gold, copper, and other metals from their ores, which after all is the department of metallurgy that requires special attention at the Royal School of Mines. In order to fill the gap thus caused, Mr. Gowland is being recalled from his retirement, a fact that constitutes a victory of science and personal charm over officialdom.

The present policy of the governors in connection with the professorship of mining is highly to be commended. It comes as a pleasant surprise to find that S. J. Truscott has been appointed assistant professor. William Frecheville was made professor a year ago, on the retirement of S. Herbert Cox by reason of ill health. He is not as young a man as he used to be, so a successor would be required at the expiry of the age-limit, so the governors have acted wisely in securing the services of Mr. Truscott when the opportunity offered. Mr. Truscott is twenty years the junior of Mr. Frecheville and is well known as the author of the book on Rand mining practice. Besides, he is an unusually facile speaker. In the ordinary course of events, he will be available as a successor to Mr. Frecheville whenever his time comes for retirement.

In my last letter I referred to the decrease in the recovery at the Carn Brea & Tincroft mine at Camborne, Cornwall, and mentioned that some of the directors and shareholders were inclined to doubt their wisdom in appointing E. S. King to the position of general manager two years ago, alleging that in spite of his high salary the content of the ore had declined and the profit turned into a loss. At the time, I stated that this attitude of the directors was unreasonable. At the meeting of shareholders this week, the directors exhibited a more cheerful tone, and Mr. King repeated his previously expressed contention that development on an expensive scale was required. When he was appointed two years ago, he called for £75,000 additional capital, two-thirds of which he wanted for development and one-third for new plant. He has obtained £25,000 for new dressing plant, but it may be legitimately doubted whether this money would not have been spent more advantageously in underground work; for it is obvious that a recovery of 19 lb. of black tin per ton will not provide profits, even at the present high price of tin, and that is all the present reserves are

calculated to yield. In the meantime, operations are to be pushed without abatement as far as funds will allow.

In my last letter I also referred to the results at Dolcoath. At the meeting of shareholders, R. Arthur Thomas gave supplementary information relating to the new discoveries. The developments at depth have been more hopeful recently than for the past year or two, and 300 ft. more sinking is to be done. With regard to the exploitation of the parallel lodes to the north, it is timely to remind your readers that there are a great number of parallel lodes in the Camborne district. The lodes now to be developed by the Dolcoath company used to be worked by the Entral company as far back as 1720, and the records, though incomplete, show that large quantities of copper ore were extracted from the slates. The cross-cut started six months ago is at the 1260-ft. level below the adit, and it was arranged at this depth in order to strike the lode within the granite where tin would be found. So far the ground developed contains 35 to 40 lb. black tin per ton by vanning-shovel assay, and it is as free from pyrite, arsenopyrite, and wolfram as the Main lode. Cross-cuts are now being driven 120 ft. above and below, and the first cross-cut is being continued in order to intersect the East Pool series of lodes. These lodes when worked at other places do not contain such clean ore as the Entral and Main lodes. Both directors and shareholders exhibited a much more cheerful frame of mind at the meeting than could have been predicted three or six months ago, when the outlook as regards future supplies of ore was indeed gloomy.

NEW YORK

INCREASE IN VALUE OF MINING SHARES.—COPPER FIGURES.—LITIGATION AT CRIPPLE CREEK.—SILVER AND GOLD MOVEMENTS.

Tonopah shares have been overshadowed by copper mining stocks in the New York share market during the past few weeks. Practically all the important copper companies show a marked advance in prices; Braden, for example, having advanced from less than \$6 to over \$8.50. All the brokers are busy figuring how much the shareholdings of the big companies have appreciated, one estimate being that the shares in 61 of the leading copper mines have increased \$128,000,000 in selling value. The copper-metal market may well be proud of its powerful influence over the 'Street.' As a matter of fact, the copper market weakened toward the end of last week, and on September 18 the A. S. & R. Co. was booking good-sized orders for November copper at 16.9c., though the figure generally asked was 17c. per pound. There is still a good deal of November-December copper to be sold, and there is no rush to place orders. Excitement was caused abroad by the report of a strike at Rio Tinto, probably based upon the strike of some employees on the railway to the mine. This is not likely to have any effect on the mine output. The fortnightly statistics show that copper stocks in England and France on September 15 were 26,010 tons, a decrease of 490 tons since September 1. Exports from this country between September 1 and 18 were 20,036 tons, as compared with 15,553 tons in the same period last year. In other words, exports have increased five or six times the normal yearly increase of consumption. It is not unreasonable to assume that Europe will get stocked up after awhile. Lake Superior and Mexico are below normal as producers, but with some of the big companies making high records for output there seems little probability of any real copper famine. Reports from Lake Superior are encouraging, and Calumet & Hecla is said to have 80% of its old employees back on its payroll. The operators continue firm in the intention to have no dealings with the Western Federation, and more ore is being hoisted than at any time since the strike began. The difficulty in securing trammers is still acute, the union having pursued its usual tactics of reducing the supply of labor of this class to a minimum before calling a strike. Even if the dispute is settled soon, it will be a long time before the Lake output gets back to normal.

The Cripple Creek district has had an unusual crop of litigation recently. The suit of the Portland against the Stratton's Independence has been finally settled after the federal court had held that the suits which had been brought against the old English company were of more effect and must be started all over against its American successor. Now R. A. C. Peterson has brought suit against the El Paso Con. Mining Co., alleging that he was defrauded of 10% of the profits derived from the recent merger. He is also suing the Colorado Mines, Railways & Utilities Co. for \$600,000 commission. The suit in the Montana courts to set aside the arrangement by which the Giroux secured control of the Butte & Ely has been dismissed, the presiding justice holding that the plaintiff had no right to begin the suit. Work on developing the properties of the New Copper Mines merger is in rapid progress, and local enthusiasts are already talking of mills and smelters. It is safe to assume, however, that the Company will not begin any plant construction until it has demonstrated an adequate ore reserve and thoroughly tested the methods of treatment to be adopted.

Nipissing is to begin shipping its silver to New York instead of to London. The point involved is merely a question of rates, the Company having found that it can send its bullion to New York at a greater profit. If the other Cobalt mines follow suit, New York can begin to compete with London as a silver market. At present London is the leader and the rest of the financial centres nowhere. Mexico, Tonopah, and Cobalt are geographically tributary to New York, and theoretically conditions ought to favor the increase of New York's importance as a silver market. Often, however, the really important conditions are not theoretical ones. It is interesting to notice that nearly \$500,000 in gold was received from Cuba last week. Normally gold is imported from France and shipped down to Cuba, and the reverse flow is another instance of the changing conditions which recently caused Argentina and Brazil, normally gold importers, to ship gold to Europe. Egypt is a heavy gold importer just now, and will probably take \$40,000,000 in return for this year's cotton crop. The output of gold in the United States last year showed a decrease of nearly \$3,500,000, and as the decline is general the world over, except in South Africa, the money markets will soon have to adjust themselves to a decreasing gold supply. In speaking of money, it should be mentioned that the old sound-money controversy was reopened last week, when the New York *Sun* discovered that some one had slipped into the currency bill a provision that Government notes could be redeemed in *lawful money*, instead of gold. When this joker was discovered, such a storm of protest went up that the bill was at once amended to provide that nothing in it should be held to be contrary to the gold-standard law. While on the subject of national legislation, it should be mentioned that ferro-manganese has been restored to the free list in the financial conference on the tariff bill, and the many hypotheses as to the probable development of the domestic manufacture of ferro-alloys become groundless.

The Inspiration Consolidated Copper Co. has applied to the New York Stock Exchange to list \$6,000,000 worth of its ten-year 6% convertible bonds. The North Butte has postponed its directors' meeting, at which an increase in capital was to have been considered. The Mines Company of America took no action on the dividend due to be declared last week, and with all the Mexican plants except one shut down, seems to be in for less prosperous times.

DEADWOOD, SOUTH DAKOTA

SUNDAY LABOR AND THE HOMESTAKE COMPANY.—BISMARCK CONSOLIDATED, WASP NO. 2, OLD IRONSIDES, AND GOLDEN REWARD CONSOLIDATED COMPANIES' MEETINGS.

Criticism of the Homestake Mining Co. by Bishop Busch, at a recent meeting of church people in Milwaukee, has been the cause of a great deal of discussion at Lead City, and culminated in a mass-meeting of citizens of that place, called by the mayor, when resolutions were unanimously adopted that censured the bishop for what was termed his

unwarranted attack upon the Company. On the evening of the meeting, and since, the resolutions have been signed by hundreds of employees and numbers of citizens whose sympathies were with the Company. Nearly a year ago, the bishop, who was at that time a resident of Lead, started a campaign for Sunday observance, in which he had the support of the clergy of the city. A committee waited upon the superintendent, T. J. Grier, and requested that the work of the Company be suspended on Sundays. After consideration, Mr. Grier refused to do this arbitrarily, but stated that the men would at any time be allowed a day off, if they arranged with their shift boss. The bishop made a strong plea from the pulpit for his church members to take advantage of this, but not many availed themselves of the privilege. It further appears that, some years ago, Mr. Grier thought it would be a good idea for the men to rest on Sunday, and orders to that effect were given. After a few Sundays the orders were rescinded at the request of the men, who realized that it was an expensive luxury, costing them \$12 to \$17 per month in possible earnings.

At the annual meeting of the Bismarck Consolidated Mines Co., held at Chicago, the following directors were elected: F. B. Hitchings, Deadwood, South Dakota; Nicholas Hampe, Rock Rapids, Iowa; W. T. Upton, Chicago; M. P. Richardson, Janesville, Wisconsin; and Irving T. Crosby, Sheffield, Illinois. The officers are: F. B. Hitchings, president and general manager; N. Hampe, vice-president; and Martin H. Kendig, of Chicago, secretary and treasurer. The property of the Company adjoins the Wasp No. 2, at Flatiron, and has been operating a 250-ton dry-crushing cyanide mill since early in the past spring. Satisfactory results have been obtained, and a surplus is being accumulated from which dividends may be expected at an early date.

At the monthly directors' meeting of the Wasp No. 2 Mining Co., held at Deadwood on September 15, Chambers Kellar, general counsel for the Homestake Mining Co., was elected to the vacancy on the board caused by the death of K. G. Phillips. The board is now composed of the following gentlemen: D. A. McPherson, John Gray, T. J. Grier, R. H. Driscoll, and Chambers Kellar. At this meeting the regular monthly dividend of 1c. per share and an extra dividend of a similar amount was declared. On the issued capital of \$500,000, this calls for the disbursement of \$10,000, the largest dividend paid by the Company this year. It is stated that \$13,000 of the earnings of the present year have been spent in extraordinary improvements, from which the stockholders will in the future draw substantial dividends.

The Old Ironsides Mining Co. has been incorporated to take over the lease and other holdings of Ringley & Co. on Squaw creek. The officers are M. T. Phillips, Central City, South Dakota, president; W. J. Ringley, Carbonate, South Dakota, vice-president; John Caretto, Lead, treasurer; and H. A. Koskie, Lead, secretary. The lease on the Old Ironsides property has until January 1, 1915, to run, and it should be productive of a large amount of good ore in the interval. Several shipments have been made, and it is the intention to continue them, and in the meanwhile an adit will be driven 500 to 600 ft. to cut the ore in quartzite and give a better opportunity for working. It is probable that the Company will purchase the property and erect a mill.

The Golden Reward Consolidated Mining & Milling Co. had a profitable year. A new mill is contemplated to handle the product of the roaster, but up to the present time its situation has not been definitely settled; it may be erected either at the roaster or at Deadwood.

Work is progressing favorably at the Heidelberg group, the property which the Deadwood Business Club is assisting to develop. The new road to the mine is nearly completed, one of the unexpected results of which was the disclosure, in the course of the work, of a body of porphyry ore which gave some startling assays. A small crew is employed in development work at the mine. This crew will be augmented when the road work is completed, which will probably be before the end of September.

General Mining News

ALASKA

JUNEAU

The Alaska Treadwell Gold Mining Co. will install in the power-plant at its mines a 225-kva. alternating-current generator and switchboard which will be furnished by the General Electric Company.

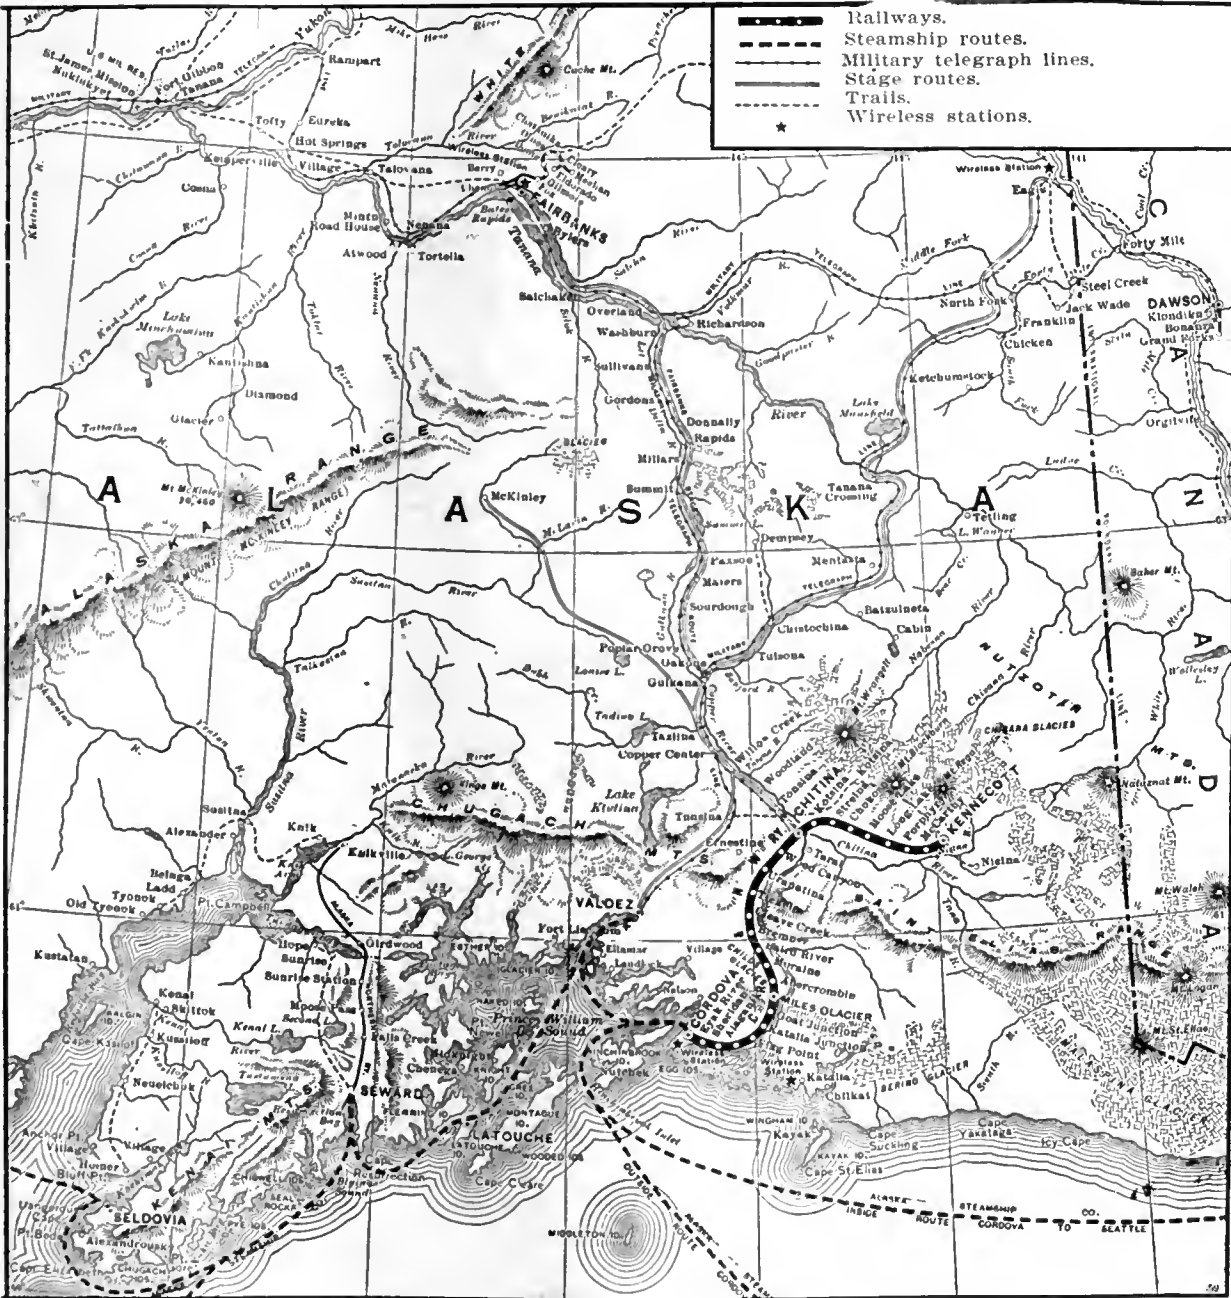

Development west of the Alexander cross-cut in the Alaska Gold Mines property has opened ore above the estimated average value of the mines' reserves. The last cross-cut, 600 ft. west of the shaft, has opened an orebody for 150 ft. and is still in ore.

SIUSHANA

The new placer district was recently examined by D.

Some prospecting has been done on some of the creeks other than Eldorado, where the discovery was made, but the work has been retarded because of the scarcity of men and provisions. On discovery claim, the prospectors are taking out about \$300 per man per day. Many of the stampeders, Mr. Cairnes said, were wandering about the country looking for claims to stake, but were unable to find them, because everything in the immediate vicinity of the find had been located before their arrival. Sufficient supplies should be placed within easy reach of the district before the freeze-up, so that they can be taken in easily during the winter.

In the Cordova Daily Alaskan of August 28 is published a description of the new field by George C. Hazelet, who recently visited the district. From Cordova the actual traveling time was 6½ days. The James claim, on Little Bonanza creek, had produced 358 oz. gold from an area

MAP OF SOUTHEASTERN ALASKA. THE SHUSHANA DISTRICT IS ABOUT 90 MILES FROM KENNECOTT AND 260 MILES FROM DAWSON.

D. Cairnes, of the Canadian Geological Survey, who gave the following description on arrival at Dawson, Yukon. The region proper comprises an area of about six by twelve miles. The 'diggings' are bounded on two sides by Wilson and Johnson creeks, and on the other two sides by the Chisana river and the summit. Within this area are most of the creeks which have been staked, including Little Eldorado, Bonanza, Coarse Money, Gold Run, and Too Late.

2½ by 16 by 80 ft. Apparatus used is crude, and the tailing will yield from 10 to 50c. per yard. Carl Whitam is cleaning-up satisfactory returns. His gravel is shallow and the creek bed is narrow. J. MacLellan and associates are sluicing on No. 3 Bonanza, and while the gravel is narrow, three men are getting 10 to 20 oz. per day. There are two main creeks with their tributaries that constitute the explored region, namely, Wilson and Johnson. These creeks

are tributaries of the Chisana, from which the find takes its name. The gold-bearing district is about 15 by 50 miles in extent, and Mr. Hazelet visited an area of about 5 by 10 miles. The ground is frozen below a depth of 5 or 6 ft., and it is believed by him that the gravel will be deep and require thawing. There are two serious drawbacks to the entire region, namely, lack of wood and water. Mr. Hazelet is sure there is good 'pay' on Bonanza from No. 1 to No. 10, and on Little Eldorado on No. 1 and 2. All this is on the Johnson side. On the Wilson side good prospects are found on Big Eldorado, Gold Run, and Glacier, with some of their tributaries, but bedrock has not been reached and nothing can be told until it is. If the camp is a permanent one the pay will largely be found in the deep bench ground, and it will take from one to two years to determine the value of the district.

ARIZONA

GILA COUNTY

(Special Correspondence.)—At the Inspiration work has been started on the installation of a No. 8 gyratory crusher and Symons 48-in. disc-grinder near the Scorpion waste dump. This machine is intended to crush ore hoisted through the Scorpion shaft, which will then be transported to the new test mill. Work is now in progress on this test mill and it should be ready for operation within a few months, as practically all crushing machinery has been received and unloaded.

Globe, September 13.

The developments for the past six months at the property of the Superior & Boston Copper Co. have been very encouraging, and there are possibilities of finding a large body of ore with depth, according to E. B. Tinker, the superintendent. On the 600-ft. level the vein is 600 ft. long, from 10 to 30 ft. wide; on the 800-ft. level the vein is 400 ft. long; the stope between No. 8 and 6 levels has so far yielded 15,000 tons of 6% copper ore, daily extraction being 150 tons; and on the 1000-ft. level the vein was not clearly defined at its contact with the McGaw cross-fault, but after driving east, 2 ft. of 15% sulphide ore was opened. Ore deposition on contacts usually occurs in the form of pockets, and the fact that in places the vein is found barren only goes to show that its occurrence at the Superior & Boston mine is no exception to the rule.

Probably a mill will be erected at the Magma within a few months, while the new electrical equipment at the mine is nearly ready for connection with the transmission line from the Roosevelt dam. With the completion of the transmission lines and installation of power plants, this power scheme will be a boon to the district.

GRAHAM COUNTY

Mining in this county is gradually getting more active. Twelve miles from Safford, is the Archise group, and churn-drilling is under way to prospect the copper deposits. Some claims on Turnbull mountain have been bonded to Globe people.

GREENLEE COUNTY

Work is to be started at the Twin Peaks. The main shaft is down 250 ft., and from 600 to 700 ft. of cross-cutting has been done. Probably a 250-ton mill will be erected to treat the gold-silver ore.

PIMA COUNTY

It is stated that churn-drills have already proved the existence of 27,000,000 tons of 1.7% copper ore in the Ajo properties of the Calumet & Arizona Copper Company.

CALIFORNIA

BUTTE COUNTY

The 25-ton cyanide plant at the Triumph mine, near Lumpkin, is nearly completed. Development at the mine is satisfactory.

PLACER COUNTY

The Iowa Hill district is quite active. The Progressive Placer Mining Co. of Ohio, in Rossi's cañon, is meeting with success. Gravel that yields \$2 per cubic foot has been opened, and the capacity of the plant will be increased to 500 cu. yd. per day. A big drag-line scraper is to be used in the work. The Big Dipper is working

a small force of men at present. The old Gleeson mine is about to be started again after being closed for lack of water.

SACRAMENTO COUNTY

It is reported that Calumet & Hecla, Michigan, engineers have bonded 1300 acres of land near Michigan Bar, and men are now prospecting with a view to future dredging. During July the Natomas Consolidated dredges produced \$175,231, the net return being \$96,222.

SHASTA COUNTY

A telegraph despatch from Redding states that, owing to defects in the gas-generating plant, the Hall desulphurizing process trials are postponed temporarily.

TUOLUMNE COUNTY

(Special Correspondence.)—The Springfield Tunnel & Development Co. has met with another flow of water in its deep gravel mine near Columbia, and may retard the progress of mining work. The three large pumps have been working steadily, but the increased amount of water seems more than they can handle. A report from Groveland states that a bed of gravel 80 ft. wide and 6 ft. thick, that will yield \$5 per cubic yard, has been uncovered in the Gold Ship gravel mine, of which William J. Graham has long been manager and superintendent. Accompanied by a mining engineer, Thomas Lane, Sr., of Angels, and John Greenhalgh are this week making an inspection of the Sonnet and Riverside mines, with a view to purchasing the properties. Recent development work at the Sonnet has resulted in opening good orebodies, and it is believed likely that a deal will be made. Active operations are to be resumed at the Columbia Basin gravel mine by A. B. Johnston, of San Francisco, who, according to report, has acquired the property. The Garfield mine, near Tuolumne, has resumed operation, and it is understood some new machinery is to be installed. William Floyd, of Soulsbyville, is the owner of the property.

Sonora, September 6.

COLORADO

CHAFFEE COUNTY

The Mary Murphy mine is owned by the Mary Murphy Gold Mining Co., Ltd., an English company, and is situated at Romley, three miles above St. Elmo, and 24 miles from Buena Vista. Recently John R. Curley, state mine inspector, visited the property and on his return reported to the *Herald Democrat*: "The Mary Murphy mine is developed by a series of adits running from No. 1 to No. 22, the latter being the lowest and driven a distance of 5400 ft. into the hill. From the breast a raise has been driven 400 ft., in order to make connection with the old workings, and has still 400 ft. to go before connections are made. At No. 14 adit, the lower portion of which was in the old workings of the Mary Murphy, was started a short time ago, and at 1000 ft. from the portal at this point a large and new orebody was opened for 300 ft., and there are no signs of its diminishing. The average width of the vein is from 12 to 14 ft., worth up to \$30 per ton. This ore is shipped direct to the smelter. The character of the ore is a lead sulphide carrying gold, silver, lead, and zinc, and with the exception of the ore from No. 14 adit, all of the ore from the mine is sent to the mill with an average value of from \$8 to \$10 per ton, including all minerals. The mine produces 150 tons per day of crude ore, the mill product being \$40 per ton in gold, silver, and lead. There are a series of aerial tramways from 2000 to 5000 ft. long, which convey the ore from the upper workings to the mill below. Seventy-five miners are employed in the mine, while 40 men are engaged at the mill. In addition to the work done by the Company, four sets of lessees are at work on adits No. 1, 2, and 3. The tonnage from the whole property is 4500 tons per month."

CONEJOS COUNTY

A recent executive order, signed by President Wilson, takes 160 acres from the Rio Grande National Forest of Colorado to provide a site for a new town, Platoro. It is pointed out that this elimination furnishes an example of how land is taken from the national forests when needed

for a townsite, or for other important public use that does not conflict with national forest purposes. This site is in the midst of a district in which recent discoveries of mineral veins are reported to have been made, and the resulting revival of mining activities created the demand for a townsite.

EAGLE COUNTY

Reports from the Brush Creek district state that the lessees on the Dakotas, said to be the western extension of the Lady Belle, have an 18-in. streak of ore that assays 300 oz. silver per ton and that a shipment will be sent out in the near future.

LAKE COUNTY (LEADVILLE)

(Special Correspondence.)—The St. Kevin Mining Co. will experiment during the winter on its silver sulphide ores, and probably erect a mill next spring.

Leadville, September 15.

TELLER COUNTY (CRIPPLE CREEK)

The tenth annual report of the Jerry Johnson Gold Mining Co. for the fiscal year terminating August 31, has been issued, and shows a production for the year of 4330 tons of ore with a gross bullion value of \$86,136. Deducting \$27,533 for freight and treatment, the net value of the ore was \$58,592, and the total amount in royalties paid into the treasury of the Company was \$14,444. The cash balance in the treasury on September 8 amounted to \$21,058. No development work has been done below the 650-ft. level; nearly all of the ore that has been shipped has been taken from the old workings at various points and not from permanent bodies, and although a large amount of dead work was done, little new ore has been found. If the property is leased again, the management will endeavor to provide for the development of the virgin ground between the 650-ft. level and the present bottom of the shaft, which has attained a depth of 975 feet.

Telluride ore assaying up to \$216 per ton has been opened on No. 13 level of the Mable M. shaft of the Gold Dollar Consolidated Mining Co. on Beacon hill. A vein of altered granite cut by a phonolite dike has shown 3 ft. of ore at the Cardinal mine, Gold hill. The additional Chilean mill is now working at the Portland mill.

The Golden Cycle Mining Co. has increased its monthly dividend rate from 2 to 3c. per share, equal to a total of \$45,000. No. 1 shaft of the Portland company is now down 1300 feet.

IDAHO

BLAINE COUNTY

The Boulder Creek Mining Co. is operating a lead property of 500 acres on Boulder creek, near Ketchum. In the Lucky Boy claim, an adit has opened high-grade galena ore, and an open-cut shows 4 ft. of carbonate and galena ore. Regular shipments are made.

SHOSHONE COUNTY

The complaint of the Federal Mining & Smelting Co. against the new schedule of the Washington Water Power

MAP SHOWING TRANSMISSION LINES OF THE WASHINGTON WATER POWER CO.

Co. increasing the rates for electricity furnished for power and lighting purposes to the mines, is the most important case to come before the Public Utilities Commission. Every mining company in the Coeur d'Alene district is interested in the outcome, and several have joined in the complaint. The commission has ordered the new schedule

suspended pending the outcome of the hearing, the date of which has not been set. The issue involved, briefly, is this: The Washington Water Power Co. has been selling electricity to the large operating mining companies in the Coeur d'Alene on contract at wholesale prices, the mining companies in turn using the power on their properties and disposing of the surplus. Some idea of the magnitude of the electrical business that has been developed is shown by the fact that the Federal company, since it made its contract for electricity with the power company, August 10, 1908, has paid that company \$900,000, and power consumers have paid \$2,200,000. On August 6 of the present year the power company filed a new schedule of electric power rates with the Public Utilities Commission, showing an increase in these rates of approximately 10%, and it canceled and superseded all preceding rates. The contract the Federal company has with the power company has not as yet expired, although made in August 1908. D. L. Huntington, president of the power company, states that the Company will oppose any reduction in rates, which are much lower than the average rates in mining districts in the United States. The service given is certainly not surpassed and rarely equaled by any other company in the country.

A much-desired report from the Hercules Mining Co. states that in August the production was as follows: concentrate, 1169 tons; slime, 907 tons; and crude ore, 1731 tons; a total of 3807 tons. Cave-ins at the mine have curtailed production during the spring. The No. 5 long adit is far from completion, having reached a length of about 6000 ft. with probably 2000 ft. yet to be driven. This will require at least another year, including the necessary connections. Eugene R. Day is manager.

The Reindeer Copper-Gold Mining & Milling Co. and the Copper Queen Mining & Milling Co. have been consolidated. The new company, the Reindeer-Queen Mining Co., has a capital of 2,000,000 shares at 10c. each, and owns 15 claims near Mullan.

The miners' rescue car of the U. S. Bureau of Mines, in charge of J. M. Anderson, arrived at Wallace during the previous week, and has been to Nine Mile, where the miners of that district, and especially those of the Tamarack, Success, and Interstate mines, were instructed in underground rescue work, the first aid, and the use of the oxygen helmet. After a week of instruction work the car was taken to Mace, where it will remain from September 23 to October 1; from there to Burke, October 1 to October 8, and then to Mullan, where it will remain until October 18. In this way the car will visit all the large mines in the district to the south.

Repairs had only been made to the 800-hp. hoist at the Greenhill-Cleveland mine, when the brakes again refused to work and the skip of steel being hoisted fell 2000 ft., the engine being badly damaged. The real cause of the accident is being investigated, while in the meantime 375 men are out of employment.

MICHIGAN

HOUGHTON COUNTY

The most important step toward the mediation and settlement of the labor troubles in the copper country was taken on September 13, when the Copper Country Commercial Club appointed a committee to investigate the strike situation and bring about an adjustment of differences. It is thought that this committee will be able to act as mediator between the mine managers and the men still on strike. The club is an influential body in Houghton and Keweenaw counties.

On September 20 the Circuit Court granted an injunction against the Western Federation of Miners from interfering in any way with the miners now at work in the district. The strikers were not pleased with this decision. The mine-owners have refused to arbitrate their differences with the men.

MONTANA

LINCOLN COUNTY

(Special Correspondence.)—C. E. Lukens, of Libby, has

purchased a half-interest in 520 acres of placer ground from William Criderman. The ground is situated 16 miles south of Libby, on Libby creek, and is believed by those interested to be rich in gold. The property is to be developed as rapidly as possible, the intention being to install a hydraulic plant, utilizing the water of Libby creek. On this placer ground there are also large deposits of a fine quality of marble, and recently a vein of onyx was discovered.

Libby, September 8.

(Special Correspondence.)—Paul D. Pratt has recently completed the work of surveying the pipe-line and ditch on the William Criderman placer claims, 16 miles south of Libby, and the development work is in progress. C. E. Lukens, of Cut Bank, Montana, recently purchased an interest in these claims, and it is the intention at once to install a hydraulic plant. According to the agreement between Lukens and Criderman, this plant must be completed by September 1, 1914.

Libby, September 16.

HILL COUNTY

(Special Correspondence.)—A company has been formed to prospect for gas near Havre. The success of the natural-gas supply at Red Cliff, Alberta, has encouraged the Havre people in the hope that their drilling will meet with good results.

Havre, September 20.

MADISON COUNTY

(Special Correspondence.)—The Mount Meadow group of claims on Willow creek, four miles southwest of Pony, is being worked by lessees. Concentrate from the 10-stamp mill is being shipped to the East Helena smelter of the A. S. & R. Co. The contents are gold, silver, and copper.

Pony, September 20.

MISSOULA COUNTY

(Special Correspondence.)—A trial car of ore from the St. Lawrence mine, near Saltese, has been shipped to the Tacoma plant of the A. S. & R. Company.

Saltese, September 20.

NEVADA

HUMBOLDT COUNTY

(Special Correspondence.)—Frank Treyer, Charles Kolback, and George Stackel are developing the old Tellulah mine in the Sierra district. It is a silver property, and after making the ventilation better, they mined some \$59 ore near a fault, the quartz vein being 3 to 4 ft. wide, of which 12 in. contained the rich ore. This shoot has tapered to a narrow streak, and it is probable that 150 ft. will have to be driven to the next shoot. Faulting has proved troublesome in this ground.

Mill City, September 6.

LANDER COUNTY

(Special Correspondence.)—The Kimberly Consolidated Mines Co. has taken over the properties of the Philadelphia Western Mining Company.

Hilltop, September 16.

NYE COUNTY

At Manhattan, the Big Four mill is crushing 100 tons of ore per day, only five men being needed for its operation. During August, 11 mines at Tonopah treated 53,182 tons of ore, valued at \$1,046,600. The Millers plant of the Belmont company is kept working full time on custom ore. On the 850-ft. level, the Extension has cut the Murray vein in the north cross-cut. It is 16 ft. wide, and on the hanging wall is a rich shoot 4 ft. wide.

NEW MEXICO

SOCORRO COUNTY

(Special Correspondence.)—The average value of the ore milled from adits B and C (East End Tunnel group) of The Oaks Co. in August was \$16.12 per ton. Average grade from adit A winze during the past month was \$20.80 per ton. A is the deepest adit now being driven on the vein. The Clifton adit of the Socorro Mining & Milling

Co. being driven on the 'Mother Lode' of the district, is expected at any time to encounter and drain the large flow of water found on the 500-ft. level in the mine last year, and which was bulkheaded at the time. It is reported that a body of ore averaging \$40 per ton was recently cut on the 800-ft. level. The mill is treating 175 tons per day.

Mogollan, September 20.

NORTH CAROLINA

MONTGOMERY COUNTY

(Special Correspondence.)—The Uwarra Mining Co., at Candor, is operating a gold-quartz property with well equipped plant. A 50-ton cyanide plant is nearly completed.

Candor, September 20.

UTAH

SALT LAKE COUNTY

(Special Correspondence.)—Another metallurgical change is impending at the Lark plant of the Ohio Copper Co., according to the rumors in circulation since M. H. Atwater completed his investigation of the mining and milling conditions of the Company. The Ohio has used no less than three systems of reducing its low-grade copper ore since the mill was put into service. As originally constructed, the Blake crusher was employed for coarse work and Chilean mills for regrinding. Then E. A. Wall had a series of rolls installed for this work, and 16 were in operation early in 1912, with an addition of four more later in the year. The Wall rolls were then removed and another type of machine tried, but is said not to have helped the recovery of copper. The mill is treating about 2250 tons per day of 1% copper ore, with an extraction of 60%, at a cost of 80 to 85c. per ton. The August production was 650,000 lb. of copper. Oil flotation has been spoken of as an aid to higher recoveries.

Salt Lake City, September 14.

The Utah Copper Co. produced 10,620,981 lb. of copper during August from the treating of 21,000 tons per day at the mills at Garfield. The Western Federation of Miners has officially declared off the strike of miners at Bingham, which started about a year ago, but full work has been under way for about nine months.

WASHINGTON

JEFFERSON COUNTY

(Special Correspondence.)—At the Tubal Cain the adit is in 2000 ft., and another 150 ft. must be driven to cut the vein. South of Mt. Constance a company is mining a manganese-copper-gold ore, the latter mineral being largely in a native condition. The vein is 5 ft. wide and from 25 to 30 tons per day of 4% ore is being stacked on the dumps. It is planned to use auto-trucks for ore transport, and the ore will then be sent to the Tacoma smelter.

CANADA

ONTARIO

The Alexo nickel mine, Iroquois Falls, shipped 550 tons of ore during August. In the Keeley mine, South Lorrain, a high-grade vein 6 in. wide has been opened. The country rock is Keewatin, and the rocks of the property are similar to those near the Temiskaming mine. The Keeley is under option to the Associated Gold Mines Co. of Western Australia. It is stated that the Wettlaufer mine will be shut down at the end of October. This mine has produced some rich ore down to the 200-ft. level, but below this the vein carried no silver content. Diamond-drilling is now being done, and 80 tons of high-grade ore awaits shipment. Since the draining of Kerr lake was started, six new veins, some containing rich silver content, have been exposed in hitherto unprospected ground.

COLOMBIA

The gold yield from three dredges of the Oroville Dredging Co. during the weeks ended August 23 and September 2 was \$5689 and \$13,650, respectively.

COSTA RICA

During July the Abangarez Gold Fields of Costa Rica

Co. crushed 6347 tons of ore, leached 657 tons of sand, and filtered 5152 tons of slime, yielding a total of \$50,249. The loss on operation was \$7295.

KOREA

The August clean-up of the Oriental Consolidated Mining Co. was valued at \$148,715, and details of the July yield are as follows:

Ore treated, tons	25,066
Tabowie mill	\$ 28,585
Taracol mill	19,699
Kuk San Dong mill	4,282
Maibong mill	17,438
Taracol tube-mill	58,159
Kuk San Dong cyanide plant	5,504
Kuk San Dong dump plant	6,713

Total\$140,380

The Candlestick mill was shut down during the whole of the month, owing to the scarcity of minera. That mill is now running, and it was hoped to keep it working the whole of August on ore broken last month and during the present month. The extraction in the Taracol tube-mill plant for July was 91%. The electric power-plant gave power for lights only up to July 28, when there was seven inches of rain which gave sufficient water to operate the power-plant at full capacity from that date. The Chorrie reservoir still lacks 31½ ft. of water of being full, so that more rain is needed. The season has been unusually dry up till now.

MEXICO

CHIHUAHUA

The San Toy Mining Co. reports net returns of \$196,075 from the sale of ore during the first half of 1913. The total income was \$205,642; expenditure, \$106,433; net earnings, \$99,209; dividends, \$57,500; and cash on hand \$464,521. The statement says that operation at the mines, which was interrupted by Constitutionalists in June, was resumed on July 22. From that date shipments have been made regularly. Twelve cars of ore were shipped in July and 30 in August. On September 1 regular railroad and mail service had not been resumed between El Paso and Chihuahua, and telegraphic communication is intermittent.

GUANAJUATO

(Special Correspondence.)—At three of the properties of the Mexican United Co., namely, the Continuacion, Agulla, and Westward, new shafts are being sunk. New equipment, including a double-drum electric hoist, air-compressor, and machine drills, is to be installed.

Guanajuato, September 12.

SONORA

The Tigre Mining Co. reports that during August the stamp-mill crushed 5557 tons of ore, and the cyanide plant treated 5184 tons of current and 1743 tons of dump tailing, yielding a total, including shipping ore, of \$119,429. The estimated profit was \$44,471.

PERU

An examination made by Carl Hand for the McCune-Haggin interests in the Huánuco goldfield, northeast of the Cerro de Pasco copper district, shows that the previous reports of rich gravels are not corroborated, and the samples taken must have been salted. It seems that in shipping the gravel to Lima and Casapalca for assaying, little if any attempt was made to prevent the operations of a 'salter.' The placera in question are along the banks and in the bed of the Huallaga river in the vicinity of Ambo, about 48 miles from Cerro de Pasco and the same distance from Goyllarisquisga. The proposed line of the Amazon Pacific railway would cut directly across the land included in the claims. Several thousand acres of land had been denounced by the various claim-holders. The McCune-Haggin interests purchased the original claims for \$67,000, while the Huánuco Gold Mines Syndicate spent a fair sum in prospecting.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

J. F. B. ERDLETS, Jr., is in Hamburg.
HERMAN A. KELLER is in Switzerland.
HOWAL A. SMITH is in New York City.
F. LYNWOOD GARRISON is in California.
H. L. HOLLIS has been in San Francisco.
THOMAS F. COLE is visiting Bisbee, Arizona.
OLAF WENSTROM was in New York last week.
ROBERT RAYMOND was in San Francisco last week.
WILLIAM B. PHILLIPS is in New York from Texas.
L. A. DECOTO has returned to Oakland from Colombia.
F. W. GRIFFIN and S. L. G. KNOX have gone to London.
STEPHEN BIACH has returned from Alaska to New York.
ALBION S. HOWE has returned to San Francisco from Costa Rica.

E. R. LEACH has resigned his position with the San Francisco Mint.

R. A. F. PENROSE, JR., is engaged in professional work in the Western states.

RALPH NICHOLS, of the Latest Out mine, Gilmore, Idaho, was at Butte recently.

R. KEMP WELCH has removed from Elk City, Idaho, to Fort Bidwell, California.

JAMES QUIRK has been appointed superintendent at the Prince Consolidated mine.

E. H. EMERSON has returned to Santiago de Cuba after a holiday in the New England states.

M. C. GODBE has been appointed assistant general manager at the Prince Consolidated mine.

J. H. HARTLEY has returned from Abangarez, Costa Rica, to Berkeley, California, for a three months vacation.

J. H. HOLMAN was not drowned in the wreck of the *State of California* as announced in our issue of August 23.

W. R. C. BEADON has been elected president of the newly formed Lower Burma Chamber of Mines, at Tavoy, India.

HOWLAND BANCROFT will be for five weeks at Boulder, lecturing on economic geology at the University of Colorado.

G. B. STREET has returned from Alaska and was at San Francisco this week investigating sulphur and pyrite supplies.

L. V. BENDER and C. D. DEMOND, of the Washoe Reduction Works, have returned from a trip of inspection to various Eastern metallurgical plants.

A. P. COLEMAN is suffering from a broken leg due to a fall while with a party from the International Congress of Geologists in western Canada.

FREDERICK G. CLAPP has returned from the gasfields of Hungary, and has gone to New Brunswick in company with MYRON L. FULLER and LLOYD B. SMITH.

ALFRED S. GUGENHEIM, F. H. MAYNARD, H. L. ROOERS, and C. D. WETMORE were among those who returned from Europe on the *Lusitania*, September 19.

R. B. BRINSMADE has been examining the Las Minas district of the state of Vera Cruz, Mexico, with a view to reopening one of the antigua mines there.

W. L. CREDEN has been appointed managing director for the Utah-Apex Mining Co., at Bingham, Utah, but he will retain his headquarters at Butte, Montana.

J. W. FINCH, R. D. GEORGE, FRED SEARLES, and A. C. LAWSON are among those present at Jackson in connection with the Argonaut-Kennedy Extension litigation.

W. G. ANDERSON, recently with the Elko Prince Development Co. at Midas, Nevada, is now superintendent for the Moccasin Consolidated Gold Mining Co., at Jacksonville, Tuolumne county, California.

GEORGE E. FARISH has returned to British Columbia and is now engaged in examining the properties of the Queen Mines Incorporated, at Sheep Creek, West Kootenay, British Columbia.

ROBERT P. ROBERTS, recently with the Great Falls smelter, Montana, has taken up his duties as metallurgist to the Mt. Lyell Mining & Railway Co., Tasmania, in place of A. L. DEAN, resigned. Mr. Dean was recently in San Francisco.

The Metal Markets

LOCAL METAL PRICES

San Francisco, September 25.

Antimony.....	12-12½c	Quicksilver (flask).....	\$39.50
Electrolytic Copper.....	17½-17¾c	Tin.....	46-47½c
Pig Lead.....	5.00-5.95c	Spelter.....	7½-7¾c

EASTERN METAL MARKETS

(By wire from New York.)

NEW YORK, September 25.—The copper market is quiet, the producers holding firm and the dealers are underbidding. Prices are being maintained, but few sales recorded. One of the largest selling agencies has quoted electrolytic copper for delivery at 16½c. A slight weakening in copper stocks is noted. Yesterday closed with October at 15.50 to 16.37; November, 15.50 to 16.25; electrolytic, 16.87 and lake, 17; castings, 16.62 to 16.75. Lead and zinc are being pressed for sale. Tin is quiet and irregular, with spot at 41.80 to 42.10. The London market closed with spot copper at £72 12s. 6d. and futures £72 10s.

SILVER

QUICKSILVER

The primary market for quicksilver is San Francisco, California, being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

TIN

New York prices control in the American market for tin, since the metal is almost entirely imported. San Francisco quotations average about 5c. per lb. higher. Below are given average monthly New York quotations, in cents per pound:

COPPER

Quotations on copper as published in this column represent average wholesale transactions on the New York market and refer to electrolytic copper. Lake copper commands normally from 1-5 to 1-4c. per lb. more. Prices are in cents per pound.

Company Reports

MAYFLOWER MINING COMPANY

This Company was organized in 1899. H. F. Fay was formerly its president and Stephen R. Dow was a director. More recently it has come into other hands, C. J. Paine, Jr., being president and A. L. Dickerman consulting engineer. The Company owns 840 acres and has sunk four shafts on several different amygdaloid beds. Production has not yet begun, work being confined to exploration. Diamond-drilling has been in progress throughout the year, one drill having been at work until April 15 and two drills the remainder of the year. The total footage drilled was 13,615, covering a rectangle 1400 ft. along the strike and 650 ft. wide. In hole No. 22 the copper content from 1012 to 1151 ft., or over 139 ft., averaged 1.2%, and for 61 ft. averaged 1.89%. More drilling work is necessary before the data can be completely correlated and shaft-sinking started, but the results are very encouraging. Receipts totaled \$97,612 and expenditures \$41,966. Assets total \$58,259 and liabilities \$2613.

MURO MAGNETIC COMPANY, LIMITED

The Company was registered in 1909 to acquire from the Murex Syndicate, Ltd., the rights for Great Britain and its colonies of the Murex process for the wet concentration of ores by a magnetic method. The capital is £210,000, in 210,000 shares of £1 each. The report for 1912 states that the value of the process on lead ores and zinc ores has been established in actual work at the Grund mine, in the Harz district, and at the mines of the Malines company in France. The value for copper ores has been demonstrated at the Cordoba copper mines, and royalties were earned there. Royalties are expected shortly from the Whim Well mines, Western Australia. A scheme of reconstruction to provide more capital is proposed. This is to form a new Company with a nominal capital of £70,000, divided into 280,000 shares of 5s. each, to take over the undertaking and discharge the liabilities of the old company, the shareholders in the company to be entitled to claim as of right one 5s. share fully paid in the new company in respect of each £1 share held by him in the old company.

ST. MARY'S MINERAL LAND COMPANY

This Company was organized in 1901, with a capital of \$5,000,000, of which \$4,000,000 has been issued. It owns the St. Mary's Canal Mineral Land Co., which was organized in 1863 to take over the 180,000 acres of land in Houghton, Ontonagon, and Keweenaw counties, Michigan, which was given to that Company by the state of Michigan for the construction of the first canal at Sault Ste. Marie. Out of this territory have been developed the Calumet & Hecla, Baltic, Trimountain, Champion, Ojibway, Mayflower, La Salle, Franklin, Winona, Copper Range, and a number of other mines. Of recent years the Company has only sold its lands for stockholdings in the companies formed. The cash receipts in 1912 were \$840,400, and expenditure on advances and assessments of various companies was \$690,030. The cash on hand at the end of 1912 was \$150,370. Only 160 acres was sold during the year, and the unsold land totals 93,224 acres, and mineral rights to 14,081 acres.

THE CENTRAL MINING & INVESTMENT CORPORATION

This Company was registered in 1905 to acquire the undertakings of the African Venture Syndicate. It carries on investment and general financial business in connection with South African gold mines, and is interested in the

Bantjes, City Deep, City and Suburban, Crown Mines, Durban Roodepoort Deep, Ferreira Deep, Geldenhuis Deep, Modderfontein B., New Heriot, New Modderfontein, Nourse, Robinson, Rose Deep, Village Deep, and Village Main Reef mining companies. The authorized capital is £5,100,000 in 425,000 shares of £12 each, all the shares are issued and fully paid. The net profit on the year's operations is £319,954. In August 1912 a dividend of 2½% was paid, amounting to £127,500, and at the end of the year another dividend of 2½% was declared, absorbing £127,500. The following summary of the work of these Companies forms an excellent review of general work on the Rand.

RAND MINES TOTAL		
	1911.	1912.
Tonnage milled	23,888,250	25,486,361
Revenue from gold won.....	£33,324,400	£36,814,804
Working expenditure	21,908,540	23,791,517
Working profit	11,415,860	13,023,287
Dividends declared	7,763,085	7,952,994
CONTROLLED BY COMPANY		
Tonnage milled	8,057,414	8,706,508
Revenue from gold won.....	£13,227,359	£14,564,700
Working expenditure	7,937,453	8,772,835
Working profit	5,289,906	5,791,865
Dividends declared	4,047,123	4,223,677

The above tables show results exclusive of the gold reserve, which was abolished at the end of the first quarter of the year by all of the mines of this group and the majority of the remainder. The separate declarations then made amounted, in the case of the Witwatersrand gold mines, to £367,991, and, in the case of the Central Mining-Rand Mines group, to £231,933, the latter being approximately the same amount as that brought forward at the end of 1911.

The total profits of the group for the year, including £236,000 gold reserve brought forward from 1911, show an increase over those for 1911 of about £734,000.

The fifteen mines comprising the group have a total maximum crushing capacity of 10,400,000 tons per annum, the chief additions during the year being at the Crown Mines and City Deep. Smaller increases of capacity have been effected at various other mines by additions to the plants and variations in the method of treatment. The average results, based on the number of tons milled for the group for the year 1912, were as follows:

	Per ton, shillings.
Average yield	33.6
Average working cost, inclusive of all current expenses incurred by the companies, except profits tax.....	20.6
Average profits tax (as estimated in quarterly reports) .	1.3
Average net resultant profit.....	11.7
Average amount of dividend paid	9.7
Average amount reinvested on capital account as nearly as can be ascertained	1.2

The remaining 0.8s. per ton represents the unappropriated balance of profit earned during the year. The total increase on balance of the carry forward figures of the various companies amounts to about £730,000. It should be noted that the profit stated in this table and in similar statements of 'net resultant profit' in the detailed summary of the various companies given above is the net cash profit obtained from the tonnage milled, exclusive of any other revenue, which is available for dividend purposes and, where required, for reinvestment in improvements in the mines to provide increased capacity in the mine or plant, or in increased claim area acquired on an annuity basis or otherwise. Great care has been exercised in calculating the ore reserves on the basis of results obtained from actual stoping experience, so that the estimated valuations are now comparable with the returns of ore treated. Taking the yield and the assay returns of the residue as together comprising 100%, the average rate of extraction is 95.6%, and the original gold content of the ore treated is 35.14s. per ton milled. This result affords sufficiently conclusive evidence that the mines are being worked as nearly as possible to the average grade of the calculated ore reserves.

Decisions Relating to Mining

Specially reported for the MINING AND SCIENTIFIC PRESS.

COAL LANDS—NOT SUBJECT TO NON-MINERAL ENTRY

Where an entryman under a non-mineral public land law is so inexperienced as to be unable to recognize existing mineral deposits upon the land, the mere fact that he has acted in good faith, and without knowledge of the existence of the mineral deposits, does not warrant the United States in allowing him to take mineral land under a non-mineral entry. In determining the character of such land, the Land Department may take into consideration not only surface indications of coal upon the particular land in question, but also the geological formation of and discoveries upon adjacent or nearby lands.

Don C. Roberts (Land Department), 41 Land Decisions, 639. March 13, 1913.

DEPOSITS OF LOW-GRADE GRANITE NOT LOCATABLE AS PLACERS

A corporation, regardless of the number of its stockholders, may lawfully locate no greater placer area under the mining laws than is allowable in the case of an individual, namely, 20 acres. It is the purpose of the mining laws to reserve from disposition and to devote to mineral sale and exploitation only such lands as possess mineral deposits of special or peculiar value in trade, commerce, manufacture, science, or the arts. Therefore an application for patent made by an electric power company for the patent of lands located under the placer laws as being valuable for the building stone therein contained was properly denied, where it appeared that the only stone thereon was vast deposits of low-grade rock of no special value for structural purposes and useful only for rough work in the immediate vicinity, while the land in question was desirable as a power-house site.

Stanislaus Electric Power Co., (Land Department), 41 Land Decisions, 655. September 4, 1912.

VOID JUNIOR LOCATIONS NOT VALIDATED BY SUBSEQUENT FORFEITURE OF SENIOR LOCATION

Where valid lode locations were made prior to 1909, and assessment work done thereon up to the present time, placer locations made in 1909 covering the same and other ground are, of course, void as to the area in conflict with the senior lode locations. The question is now asked as to what would become of the conflict area if the lode locator fails to perform his assessment work. Would such area, upon expiration of the time for performing the lode assessment work, fall under the existing placer location? This question may be answered in the negative on authority of the decision of the United States Supreme Court in the case of *Farrell v. Lockhardt*, 210 U. S., 142, which in effect overrules the former decision in *Lavagnino v. Uhlig*, 198 U. S., 443, on this point. The failure of the lode claimant to perform his annual labor within the time prescribed by law would leave his claim open to re-location under any location made subsequent to the date of forfeiture, but it would not operate to validate locations attempted to be made on said ground at any time prior to such forfeiture. The same may be said with reference to an additional lode location made in 1912 on ground already covered by placer locations. If those placer locations were valid locations on the date at which the lode claim was located, the lode claimant gained nothing and never can gain anything by that location. If, however, as a matter of fact, no assessment work had ever been done on placers located in 1909 and 1910, they were open to re-location in 1912, and the lode location took effect. The mere fact that the placer claimants have recorded proofs of labor in previous years does not establish the fact that the annual labor was actually performed. That is a matter of fact which may be determined according to the evidence. Recording the proof of labor merely raises a *prima facie* presumption that it has been done, which presumption may be rebutted by evidence to the contrary.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

HYDRO-ELECTRIC POWER INSTALLATIONS in the French Alps represent a maximum of over 475,000 hp., with a minimum at lowest water of 180,000 horse-power.

AFTER the valuable oil has been distilled from eucalyptus leaves in certain parts of Australia, the residue is found to contain a useful non-corrosive for steam boilers, which prevents the formation of scale.

A DRILLING CONTEST at Ely, Nevada, for a prize of \$1000 was held on September 13, and won by W. M. Salverson and James Garnier, who drilled 34 $\frac{3}{4}$ inches in 15 minutes, against 32 $\frac{1}{2}$ in. driven by Otto Cruciani and Martin Karich.

TRANSPORT OF PULP to the Homestake slime plant is done by means of a 12-in. cast iron pipe, 3 $\frac{1}{2}$ miles long. The grade is 1% and the proportion of solid matter to water is 1080 to 2506 parts. Details were printed in the *Mining and Scientific Press* of April 6, 1912.

'GNAMMA HOLES' and 'soaks' are Western Australian terms meaning rock-holes containing water on bare exposed granite and porphyry surfaces, and containing water in sandy granite basins, respectively. The former depend on rain for replenishment, while the latter act as a sponge and often furnish a perennial though limited supply of fresh water.

THE Neal patent pebble-retaining outlet consists of two parts: a baffle made of suitable hard material placed inside the tube-mill, and a reverse screw which returns to the tube-mill any pebbles which might escape the baffle, although it permits of the free escape of water-borne pulverized pulp. Even if the tube-mill is filled with pebbles as high as 3 in. above the centre level, it is found that the baffle alone will retain the pebbles. The baffle is so designed that at whatever angle the pebble strikes it, the pebble is returned within the body of the mill, providing the mill is revolving at its due speed. In addition to the baffle, however, the reverse screw is so effective that, even if the mill is revolved slowly instead of at its proper speed, the spiral still retains the pebbles within the body of the mill.

ALL CLASSIFIERS which classify by a rising current of water have a feature which is called the sorting column, in which the sand is trying to settle, and is allowed to settle or is prevented from settling, according to the size and weight of the grains, by the velocity of the rising current of water, a stronger current lifting larger and heavier grains, a weaker current lifting smaller and lighter grains. This sorting column, whether square or cylindrical in shape, will have adverse downward currents of water carrying slime down into the spigot, thus defeating the whole object of classification unless some special provision is made to stop it. To obtain better classification and prevent the adverse down currents, two methods have been employed: (1) causing a vortex or horizontal rotation in the sorting column, and (2) using a pulsating rising current.

WHEN a strong alkaline solution has to be clarified with basic lead acetate, the solution must first be neutralized with acetic acid. This addition of acetic acid has to be made slowly and carefully, as the solution otherwise easily becomes acid, which prevents the formation of a lead acetate precipitate. This is entirely avoided if neutral lead acetate is substituted for basic. If neutral lead acetate is introduced into a solution containing oxide of lime or saccharate of lime, the lime combines with the acetic acid to form acetate of lime with formation of hydroxide of lead, which in its turn, when all the lime

is neutralized and all combined sugar set free, reacts with the excess of the reagent, thereby producing basic lead acetate which precipitates the organic impurities.

The accompanying flow-sheet is that of the Victoria mill of the Waihi company, New Zealand. As the result

FLOW-SHEET OF WAIHI MILL.

of the treatment, the percentage of each product sent to the cyanide plant is approximately as follows: sand 18.63%, slime 80.09%, concentrate 1.28 per cent.

UNDERGROUND WORK in the 15 mines controlled by the Central Mining & Investment Corporation, on the Rand, is summarized in the 1912 report as follows: Operations on seven mines of the group show that 984,650 tons of sand has been lowered into the worked-out stopes during the year at a cost, including all charges, of 1.28s. per ton. The application of this process has proved extremely valuable in supporting the ground in the vicinity of the main shafts and in controlling the settlement of the rock in worked-out areas. Eight of the mines of the group are now equipped with ventilating fans inducing a total delivery of 963,000 cu. ft. per minute into the mines they serve. This is equivalent to about 50 cu. ft. of fresh air per man per minute in addition to the natural ventilation of the mines concerned. Mechanical means for the transport of ore through the stopes and along the main haulage-levels in the mines is being increasingly adopted. On the thirteenth level of the Crown Mines the normal amount of ore transported by trains drawn by electric locomotives is 4000 tons per day. During the year an act was passed by the Union Parliament to provide for the establishment of a compensation fund for miners who have already contracted miners' phthisis, and an insurance fund for future requirements. In addition to providing for the levies under the first fund, the mines have, during the first two years, to contribute to the insurance fund a sum equal to 2 $\frac{1}{2}$ % of the employees' earnings, and after the first two years 5%, the employees contributing 2 $\frac{1}{2}$ % throughout. A committee was appointed by the Minister of Mines to inquire into methods for the prevention of miners' phthisis. A preliminary report has been issued by this committee containing recommendations for a comprehensive system of water spraying throughout the mine workings. This has already been adopted very largely with beneficial results. Rock-drills, air, and workshops costs have been the subject of close attention during the year, and improvements in organization have been effected, resulting in economy of air power for rock-drill requirements, and in a considerable saving in workshop costs. The saving effected in improved organization and equipment has assisted in meeting the increased charges on the mines due to the adoption of an eight-hour day underground, the increase of native wages, and in native recruiting costs, miners' phthisis legislation, water-spraying equipment, and other systems introduced for the further benefit of the underground employees.

Mineral Production of California

By CHARLES G. YALE

*The mine output of gold, silver, copper, lead, and zinc in California in 1912 was valued at \$26,383,946, an increase of \$1,209,269 over the corresponding value for the year 1911. The increase is due mainly to a gain in yield of gold from deep mines, increased value from copper and silver, and increased output of zinc. The greatest gain was in the value of copper and was due to an advance in commercial value of the metal, as the quantity produced was materially less in 1912 than in 1911. To a less degree the same may be said of silver, and the zinc quantities and values also increased.

The mine production of gold in 1912 was valued at \$19,713,478, a nominal decrease of \$25,430 from 1911. The output of silver was 1,300,136 fine ounces, valued at \$799,584, an increase of 29,691 oz. in quantity and of \$126,248 in value. The production of copper was 33,451,672 lb., valued at \$5,519,526, a decrease of 2,864,464 lb. in quantity, but an increase of \$980,009 in value. The output of lead was 1,144,731 lb., valued at \$51,512, which is a decrease of 253,380 lb. in quantity and of \$11,403 in value. The output of zinc was 4,345,591 lb., valued at \$299,846, an increase for the year 1912 of 1,538,556 lb. in quantity and \$139,845 in value.

There were 1041 metal-mining properties reported productive in 1912, of which 532 were deep mines and 509 placers of various kinds. This shows a total decrease of 140 producing mines in 1912. There were 470 deep gold mines, 12 silver, 24 copper, 25 silver-lead-zinc, and 1 zinc.

Of the placer producers, 141 were hydraulic mines, 65 dredges, 146 drift, and 157 surface or sluicing mines. There were 64 less deep and 76 less placers producing in 1912 than in 1911.

*U. S. Geological Survey Report.

The deep mines of California produced 2,641,497 tons of ore in 1912, a decrease of 155,764 tons. Of this output 2,225,429 tons was silicious ore, 408,622 tons copper ore, 974 tons lead ore, and 6472 tons zinc ore. The silicious ore output decreased 70,918 tons, the copper ore decreased 85,659 tons, the lead ore decreased 1034 tons, and the zinc ore increased 1847 tons.

The total average value of all ore sold or treated in California in 1912 was \$6.71 per ton, against \$5.49 per ton in 1911 and \$6.71 per ton in 1910. At gold and silver mills in California in 1912 the tonnage milled was 2,077,300 short tons, yielding \$10,371,347 in gold, and 307,306 oz. of silver valued at \$188,993, or an average value in gold and silver of \$5.08 per ton, compared with \$4.64 in 1911 and \$5.25 in 1910. Of this average value, \$4.17 was recovered as bullion in batteries and on plates in mills. The smelting ores, 456,735 tons, produced all the copper and zinc and practically all the lead, as well as 955,067 fine ounces of silver, valued at \$587,366, and \$592,532 in gold. There were also treated 107,462 tons of old tailing, yielding \$103,936 in gold, an average of 96c. per ton, and \$1298 in silver, an average of 1c. per ton.

The placers of California in 1912 yielded \$8,645,663 in gold and 35,652 oz. of silver valued at \$21,926, a decrease of \$339,895 from the placer output of 1911. The hydraulic mines showed an increase of gold output of \$14,196, the dredges a decrease of \$236,506, the drift mines a decrease of \$91,908, and the surface placers a decrease of \$26,646 in gold. The placers produced 43.86% of the total gold yield of the state and the deep mines 56.14%. The dredges produced 37.68% of the entire output of gold in the state in 1912 and 85.93% of the placer gold. The total gold-dredge output of California from 1899, when only \$206,302 was produced, has been \$55,415,191, including the \$7,429,951 obtained from this source in 1912.

The following table shows the mine output of California by counties in 1912:

	Ore treated.	Gold. ^a	Silver. ^a	Copper.	Lead.	Total value.
	Tons.		Fine oz.	Pounds.	Pounds.	
Alpine.....	1,200	\$1,764	2,300			\$3,179

^a Includes placer production.
^b Includes value of 4,345,591 pounds of zinc.
^c Includes only gold recovered by dredging in these counties; other output of Shasta and Siskiyou counties given below.

ALTHOUGH the origin of schists at Kalgoorlie has been often stated to be sedimentary, their occurrence only along shear or fault planes in igneous rocks invalidates this conclusion, and the graphite cannot be considered to arise from organic carbonaceous matter. Moreover, the occurrence of a quartz-carbonate fissure-vein carrying graphite in the Great Boulder mine, No. 12 level from Hamilton's shaft, is further evidence of its inorganic origin, according to J. Malcolm MacLaren. It would be idle to speculate on the source of the carbon, except to point out that the prevalence of carbonates in the rocks in which the graph-

ite occurs and the deep-seated nature of the alterations that have produced them. The occurrence of marsh gas (CH₄) is probably to be considered as a result and not a cause of the presence of the graphitic schists. The vein occurrence of graphite, and its intimate association with igneous magmas are well known.

A USEFUL SPECIES of the eucalyptus family on Western Australian goldfields is *eucalyptus salubris*, a spirally twisted variety which is exceptionally strong, and although the average tree is about 4 in. diameter, it is suitable for mine timbering, such as laths above drift sets.

SMALL reverberatory furnaces for the smelting of copper ores are not in the fashion nowadays, and it is correspondingly interesting to learn that two furnaces with hearths $11\frac{1}{2}$ by 23 feet are under construction at the Messina copper mines in the Northern Transvaal. Coal will be used as fuel, seven or eight tons being required to smelt the 20 tons of ore which it is expected each furnace will treat daily.

BUTTE citizens have recently gone on record to the effect that 'Boston Coppers,' through their oppressive methods, have proved themselves unfit to control and manage such a vast public trust as Lake Superior mines and are "firmly of the opinion that the time has come for the federal government to assume full charge of those properties." If a fair return to the shareholders is to be included in the criterion whereby the fitness of the management is to be judged, it would be difficult for the 'citizens' of Butte to establish their point.

IN West Virginia a workmen's compensation law has recently gone into effect, and three-fourths of the mining companies have already filed notice of their intention of complying with its provisions. The employer is required to pay 90 per cent and the workman 10 per cent of the assessment, which shall not exceed 1 per cent of the payroll. Injured employees receive half-pay, not to exceed \$8 per week, and in case of death the state pays the necessary funeral expenses, the widow receives a pension of \$20 per month, and each child receives \$5 per month until it attains the age at which it can legally be employed.

PROPOSALS to place cyanides of potassium and sodium on the free list, discussed in our issue of September 13 by Mr. G. H. Atkins, are being vigorously protested in the East. In a recent letter to the *Oil Paint and Drug Reporter*, Mr. Jacob Hasslaeher states that American production of cyanide of sodium amounted in 1912 to over 10,000,000 pounds. He also states that this was genuine manufacturing, as it would not pay to import the high-grade cyanide and merely dilute it. The American manufacturers use the Castner-Pfleger synthetic process and maintain that a reasonable tariff will permit the building up of a local industry that admittedly would be of importance. Further discussion of the matter is likely to be of academic interest only, as the tariff bill is expected to be completed this week. Looking upon protective tariffs, as we do, as necessary evils at best, our feeling is that no such tax should be levied except after the most complete demonstration of its need.

CHILE has undertaken to subsidize an Austro-Hungarian shipping company, which will maintain direct service to Mediterranean ports, in the hope of developing fresh markets for nitrate among the agricultural population of the countries bordering on that sea. During the year that ended on June 30, 1913, the production of Chilean nitrate was 59,450,454 quintals of 101.41 pounds each. The price declined from \$2 to \$1.84 per quintal during the year.

AMERICAN manufacturers have not made a strong showing lately in securing contracts for furnishing the equipment of American enterprises in South America. Not long ago the power-plant contract for the Chile Copper Company went to German bidders, and now Mr. C. M. Schwab has gone to Germany to arrange for the building of ten ore-carrying steamers of 15,000 tons capacity each, for the transport of iron ore from Chile to the Atlantic coast of the United States.

REMOVAL of the injunction against picketing in the Lake Superior district has been construed by the striking miners as the granting of a license for disorder and riot. After several weeks of comparative calm, the strikers have abandoned peaceful methods, and negotiation has given place to rioting. Just what will be gained by this change in attitude is a question, but if the future is to be judged by the past, the recent outbreak does not augur well for organized labor.

THE concept of petrologic provinces has proved fruitful, and as Mr. Thomas T. Read shows in this issue, it may be carried over usefully into metallurgy. It is easy to point out that the absence of copper and wide presence of lead has shaped the development of smelting in Colorado as the reverse has operated in Montana. Ease of transportation and many industrial factors, it is true, interfere with any strict delimitation of a metallurgic province, but as a broad underlying concept the idea is worth consideration. Mr. Read has chosen for discussion of its application one of the most important and most active metallurgical regions in the World, our own Southwest, and his comparisons of practice at the smelters of a whole region will, we are sure, prove more useful than the same space devoted to routine description of plants.

COINCIDENT with our publication this week of the details of the Howe process as developed at the Gwalia Consolidated mine, comes the announcement from London that further operations are to be suspended. The figures we print are based upon experiments made in June and come to us direct from Australia by mail. According to reports from London, cabled results of later tests were so unfavorable as to force abandonment of operations. It is said that fuel consumption ran up to 62.7 per cent, and that the extraction was but 36.4 as against 85 per cent reported in July. It is difficult to understand this discrepancy and particularly to believe in the high fuel consumption. It seems possible that some error has occurred in transmission of the figures, and we shall await confirmation with interest.

GOLD output in British Guiana is showing an encouraging increase, the exports between January 1 and August 28 having been 50,653 ounces, as compared with 28,860 in the same period last year. Most of this increase is due to the recent discovery of rich placer ground in the Cuyuni district.

IT is easy to formulate a theory of ore genesis, but difficult to determine which of several theories is correct. In the articles on the Coeur d'Alene ore deposits, of which we print the second and final installment this week, Mr. Hershey presents strong evidence in favor of sedimentary origin. He does not claim that it has been demonstrated to be the solution of the problems of the field, but he does claim, and we believe with reason, that sufficient evidence in its favor has been massed to warrant suspense of judgment as between this and the magmatic hypothesis. The mere fact that such diverse conclusions have been reached by Mr. Hershey and Mr. F. L. Ransome, indicates how far we still are from possessing positive criteria in the study of ore deposits.

DESPITE announcement of the vice-president, Mr. Hayes, of the United Mine Workers of America, that the striking Colorado miners would "conduct their campaign upon a high plane," Robert Lee, one of the marshals was almost immediately murdered. With 'Mother' Jones as the mouthpiece of the organization and the beginning of the campaign inaugurated with bloodshed, it would seem that a perverted conception of 'high plane' obtains in the mind of someone connected with the strike. Agitation of the 'Mother' Jones brand and bloodshed will do more toward spelling failure for the cause of labor than all elements for the good combined can counteract. We regret this greatly, since, notwithstanding a few slips, the United Mine Workers has had good leadership and has generally stood in an entirely different category from the I. W. W. or the Western Federation of Miners, for example.

METALLURGISTS, whether connected with the iron and steel industry or not, will find much of interest in the program for the autumn meeting of the American Institute of Mining Engineers, now being arranged for October 16 and 17 by the Iron and Steel Committee. The first session will be devoted mainly to blast-furnace gas cleaning, the slagging producer, and the generation of heat from waste gases. At the second session will be discussed problems of briquetting and the use of powdered coal for fuel, a movement deserving close attention from engineers in many lines of practice. The meetings on the second day will be devoted to discussions of technical phases of steel production, though a paper by Messrs. G. H. Clevenger and B. Ray on 'The Influence of Copper upon the Physical Properties of Steel' is likely to be of general interest. The meeting will be held at Institute headquarters in New York and is to close with a dinner on the evening of October 17. To this, as well as to the sessions, special invitations have been sent to members of the American Society for Testing Materials, the American Iron and Steel Institute, American Society of Mechanical Engineers, American Society of

Civil Engineers, American Society of Electrical Engineers, and the American Foundrymen's Association. The Iron and Steel Committee has already won prestige of success and is setting a high standard for the other committees of the Institute. We understand that the new Committee on Mining Law is to have charge of the program at the February meeting and that other committees are in turn to have similar opportunities. This careful planning of the programs of the Institute meetings, focusing each on some group of subjects, is proving extremely effective in increasing the interest in the technical sessions.

Launching a Republic

Present political and economic conditions in China are in many ways of interest and importance to Americans, and the efforts to develop a republican form and method of government in that country presents many interesting analogies to the problems which beset the population of the thirteen states during the period of stress which followed the Revolutionary war. In China, after centuries of government outwardly despotic, but in many ways essentially democratic, the beginnings of national unity have exhibited themselves in a demand for a republican form of government, and Yuan Shih-kai, a strong military leader and far-sighted man of affairs, has been entrusted with the presidency of eighteen provinces, containing a population variously estimated, but certainly not less than 350,000,000. There, as with us in 1780, the problems are essentially tripartite: the necessity for arriving at a working arrangement which will permit the national government to exercise its necessary functions, without unduly encroaching upon the rights of the states or provinces which had previously been in large degree autonomous; the development in the people, concerning republican institutions, of a group of ethical and practical ideas for which there is no word in English, but which the Germans call *sittlichkeit*; and finally, the providing for the refunding of a large national debt and the development of trade, commerce, and natural resources as the basis of a lasting national prosperity.

It will be useful, in obtaining a proper perspective, briefly to recall the status of affairs in this country in 1784. At that time the states had just emerged from a war which had cost \$140,000,000 and had left them burdened with a national debt of \$40,000,000; truly a staggering sum to a population of less than 3,000,000, whose average scale of living was so near the border of necessity that well-to-do families enjoyed less of luxury than the ordinary workman of today. Party feeling ran so strong that it was seriously proposed to assassinate Alexander Hamilton because he advocated allowing to Tories the peaceable enjoyment of their lives and property, and the individual states were so jealously concerned with safeguarding their individual rights that they lent but scant support to the central government. The outlook was indeed a gloomy one, and prophecies of speedy disaster were rife. Nevertheless, the United States of America has never ceased to prosper

and has now taken a place among the leading powers of the world.

Present problems in China differ somewhat from those which first beset us. 'States rights,' while they must be considered, form no such exigent matter as faced our statesmen in 1870. The development of a republican habit of mind is more of a task than it was among the sturdy Scotch-Irish, Covenanters, Huguenots, and Dutch who were the first ingredients of the melting-pot here. Well informed observers have estimated that not more than 2½ per cent of the population of China took any part in the recent revolution, and a large part of the populace is perhaps still ignorant that it has transpired. Universal suffrage is out of the question under such conditions, for citizens who are unaware of what is happening in the internal and external relations of their country cannot vote intelligently concerning them. The importance of this can easily be overestimated, however, for where population becomes dense and the political units large, it becomes almost impossible to keep the general public well informed of what is happening in their government. It might with equal accuracy be pointed out that a very small proportion of the population of New York City has any idea of the sums annually derived by taxation, for what they are expended, whether these expenditures are wise or unwise, and what are the real forces which actuate the movements of their machine of civic government. Officials in China have been and probably will be corrupt, but it is doubtful whether anything so vicious will ever be uncovered in that country as the relation which recently existed between the police and organized vice in New York. These problems are neither Oriental nor Occidental; they are problems of human nature. It is safe to venture the prophecy that for some time government in China must remain in the hands of a comparatively few strong men, but that with the enlightening influence of the public press and the catalytic action of the returned students, who have obtained an international viewpoint and sense of balance through study in Western universities, the nation will steadily advance in the development of a republican form of government. So far as practical results are concerned, a republic seems to offer comparatively little advantage over a monarchy, but it is evidently in line with the evolution of institutions, just as the colt was in line for the development of the horse, while the trilobite was in line for the development of nothing useful.

Finance is a critical problem in China. The national debt is now approximately \$900,000,000. This is less than \$3 per capita, as compared with our own debt of \$15 per capita in 1784; but the circumstances in the two cases present fundamental differences. In the one case a few people were scattered about the borders of a vast area of virgin natural resources, awaiting only well directed labor to produce great wealth. In China a dense population inhabits a region of which the agricultural resources are already intensively developed. Vast resources of coal and iron, the fundamental bases of trade, still await development, but the rela-

tive possible expansion in China is obviously much less than was the case in our own early history. The huge size of its economic units makes its problems infinitely more critical; mishaps in handling marbles are not serious, while cannon balls may work havoc. Continual internal unrest in China, such as was recently exhibited as a by-product of the too-advanced ideas of the southern 'republicans' (the *Kuo-ming-tang*) is likely to prove fatal. The fixed expenses of the government are high, and if the proceeds of provincial taxation are not forthcoming and the funds of the government are perforce devoted to the suppressing of rebellion, the end is not far to foresee. Recent reports, of perhaps doubtful authenticity, state that present receipts are less than one-third of expenditures. In such a situation it is urgently necessary to restore quiet and order, even at some sacrifice of idealism, in order that a catastrophe may be averted. Lord Cromer has pointed out that when a nation combines destruction of internal income with the incurring of foreign debt the outcome is inevitable. If China wishes to avoid Egyptianization, it is urgently necessary for her to place the statesman and man of affairs above the political agitator. Fortunately, both the characteristics of her people and the evidence of recent events indicate that this will be done.

President Huerta's Message

The recent message of President Huerta to the Mexican Congress at the opening of the second period of sessions on September 16, has a tone of general hopefulness on the part of the executive for a speedy solution of the internal difficulties of the country. From a great many standpoints the government is to be congratulated on the progress that has been made during its brief administration and under the most trying circumstances; and whatever may be thought of the circumstances under which the provisional government was established, the message carries the impress of a strong man making real progress against amazing difficulties.

International relations are but briefly discussed, the message being devoted almost entirely to a report of the administration and the hopes and purposes of the government. In referring to the recent strained diplomatic relations with the United States, the President says: "I have only to state that the government has well grounded hopes that an early solution will be found for the difference that just now holds in suspense the relations of good and long standing friendship destined to bind us for an indefinite future with our powerful and civilized neighbor." In the major portion of the message dealing with the affairs of the government, it is gratifying to note the marked progress that is being made despite the handicap of disorder under which the administration is laboring. The financial statement reports the revenue for the past fiscal year at \$120,500,000, which is greater than any high fuel consumption under the Diaz régime. Last error has occurred in \$15,300,000 in excess of that of and we shall await counted for by \$7,600,000 being

derived from new taxes and \$7,700,000 as an increased yield from the existing taxes. The expenditures for the period under review have not been fully reported, owing to a large extent to lack of facilities for communication. The disbursements for the first eight months of the year amounted to \$65,100,000, which, if the same rate obtained for the rest of the year, would amount to \$97,650,000 for the year, and would afford a surplus of \$22,850,000. However, as pointed out in the President's message of last April, no hopes for such a balance are entertained and a deficit is expected.

The judicial reforms which are recommended provide for the establishment of conciliatory courts (*juzgados de paz*) whose jurisdiction and methods of procedure will be such as to realize the long-standing desideratum of affording cheap and efficient justice to the poor. Such courts properly regulated will fill a long felt want in Mexico's department of justice, and it is hoped that this recommendation will receive congressional support. In dealing with the department of Fomento, the efforts which are being made to find a satisfactory solution of the agrarian question are to be noted as bearing fruit. During the first half of the year 46,485 hectares of national land were converted into private property. The agrarian question is generally conceded to have a most important bearing on Mexico's future, and has been the cause of many uprisings and revolutions in the past, of which the Zapatista warfare which has kept the states of Guerrero, Puebla, Michoacan, Morelos, and Mexico in a state of unrest for the past two years, is an example. At the present time lands are being surveyed in San Luis Potosi, Michoacan, Veraacruz, Tabasco, Chiapas, Lower California, and in the Federal District with the object of making it available for small farmers, a movement which it is believed will do much toward eradicating existing class feeling and will have a powerful influence toward pacification. The government realizes that the pacification of the country is urgently necessary for the normalization of public services and the re-establishment of political, social, and economic equilibrium and the conduct of a broad program of reforms. It is to be hoped that the Mexican people will awaken to the task before them of bringing about that union which the Republic demands and which power of accomplishment lies wholly within the people themselves. As the President points out in his message, it is indispensable that all Mexicans without distinction or political or religious creeds, stand shoulder to shoulder for the laudable purpose of maintaining intact the inheritance of the race and the prestige and integrity of the nation. While the President intimates that American men-of-war will not be welcome in Mexican waters after October 25, we trust that there will be no occasion for keeping war vessels in Mexican ports after that date, although such good fortune is hardly anticipated. No doubt the matter will be adjusted satisfactorily. He would be an over-bold prophet who should attempt to say what the month may bring forth in Mexico, but at least there are evidences of distinct progress, and we are warranted in maintaining a hopeful as well as friendly attitude.

Copper Smelting Practice in the Southwest

By THOMAS T. READ

A concept which has proved useful to geologists is that of the existence of petrographic provinces, or areas in which characteristic and often related types of rocks occur and in which characteristic minerals and mineral associations can be discerned. It therefore follows that metallurgical provinces can also be distinguished, since the choice of metallurgical methods employed in the treatment of metallic ores is often decided by the characteristic minerals present in that ore. The states of Arizona and New Mexico, together with the adjacent parts of Mexico, may thus be considered as roughly constituting such a metallurgical province, especially if the inquiry is limited to the ores of copper. In this area, in 1912, approximately one-third of the total copper output of the United States was produced, chiefly from ores that exhibit many characteristics in common. It is natural, therefore, that the metallurgical methods employed should also exhibit common characteristics. It is not my purpose to attempt to present here any profound research into the fundamental relations between the climatic, topographic, geologic, and economic conditions here prevailing, and their effects, as exhibited in past and current practice, but rather to indicate in a somewhat sketchy fashion only a few of their more salient features. It will be impossible because of the limits of space to enter into any discussion of the history of the area under discussion, and since this has recently been admirably done by James Douglas*, than whom no one could speak with more authority, there is indeed no necessity to make the attempt. These remarks are, therefore, based upon present practice as it has crystallized in the light of years of experience.

Situation of the District

Bounded by the Rocky Mountains on the east, and the Sierra Nevada on the west, the region under discussion may be regarded as in part a southward extension of the Colorado plateau and in part the northern portion of the Mexican plateau. The Colorado river may indeed be considered to form its northern and western boundary as it threads through its profound cañons in its course from its headwaters in the Rocky Mountains to the Gulf of California. Though bordered by such a mighty river, the entire region is arid, and in some parts a true desert. It will be remembered that the prevailing westerly winds from the Pacific Ocean exhibit their maximum force, with its resulting damp climate, from Juneau south to San Francisco. South of San Francisco the coast sweeps away eastward, while the trade winds swirl away to the south and finally west. As a result, the climate of that part of the United States lying south of 40°N. latitude and between the Sierra Nevada and the eastern front of the Rocky Mountains is almost entirely arid. This peculiarity not only affects the character of the ore deposits, as

altered by subaerial agencies, but by its effect in such important economic questions as food, water, and timber supply, and character of population serves to determine in a marked degree many of the salient features of the mineral industry. In its flora and fauna, including in the latter its human population, this region differs in many respects from every other part of the United States, with the exception of the adjoining parts of California.

Copper Deposits

The copper deposits found in this region are, as might be expected, characterized by outcrops of oxide and carbonate minerals, Arizona being famous

MAP OF ARIZONA.

for its specimens of malachite and azurite. At varying, but usually considerable depths, the oxidized minerals give way to secondary and even primary sulphides. The orebodies are of such multifariousness and occur in such a variety of enclosing rocks that no attempts at generalization would be useful. These orebodies are commonly regarded as marked examples of the concept that copper orebodies are typically marked by a surface zone of oxidation, a succeeding zone of secondary enrichment, and a bottom zone of primary ore. This conception, at first extremely valuable, is beginning to outlive its usefulness and remains to hamper free thought. In a recent paper on the Bisbee deposits, A. C. Notman employs the term 'underground gossan'; surely a most confusing name for an obscure concept. As a matter of fact oxide minerals occur both above and below the sulphides. Thus, at the Chino mine, at

*'The Copper Queen Mines and Works,' *Trans. Inst. Min. and Met.*, March 1913.

Santa Rita, in New Mexico, the oxide ore in places extends to 1100 ft. in depth, while sulphides occur close to the surface and overlying the oxides.

Where the ores are rich enough to stand the cost, they are mined by methods appropriate to the size and character of the deposit and smelted directly.

OLD DOMINION SMELTER.

In the early work so small an amount of sulphide was available that the oxides were smelted to yield black copper. In practically every district enough sulphide ore is now available to allow smelting with the formation of matte, and in many cases a certain amount of sulphide has to be roasted, though in others the charge balance, for blast-furnace smelting, is somewhat short of sulphur. The tendency of present practice is toward concentration of the low-grade sulphides and leaching of the oxidized ore. More than a half dozen large concentrating plants are already at work, but, with one exception, the leaching work has as yet not progressed beyond the experimental stage. Most significant in its probable great importance is the experimental work with the flotation process which is being carried on at the Inspiration mine. If the 600-ton plant now in course of construction proves as successful as the experiments made with a 50-ton plant, it is unquestionable that profound changes in present practice in this district are to be expected.

Smelting Plants of the District

There are now in operation in the district under review eleven important smelting plants, and preliminary plans for the construction of a twelfth are well advanced. The El Paso smelting plant of the American Smelting & Refining Co. is included in this list, since it draws its supply of copper ore chiefly from this area, though situated beyond its margin. As typical examples of the range of practice, the Old Dominion smelter at Globe and the A. S. & R. smelter at Hayden may be cited. The ore supply of the former is lump ore, which is smelted in blast-furnaces. At the Hayden plant all the ore is subjected to preliminary wet concentration, the resulting concentrate being roasted and smelted in oil-fired reverberatory furnaces. Present conditions all tend toward an increase of reverberatory smelting. The amount of ore of high enough grade to permit direct smelting is limited, while, on the other hand,

at the Chino 90,000,000 tons of concentrating ore has been developed, at the Ray 84,000,000 tons, at Inspiration 45,000,000, and at Miami 21,000,000. It is evident, therefore, that future tendencies will be toward an increase of reverberatory smelting. L. D. Ricketts has given the cost of reverberatory smelting at Cananea during the period from February to July 1911, as \$2.22 per ton, from which must be deducted \$0.82 as a credit for the value of the steam generated by the heat recovered in the waste-heat boilers, making the net smelting cost \$1.40 per ton smelted. Of the total amount thus smelted, one-third was flue-dust, and the apparent cost of blast-furnace smelting must be increased by an amount equivalent to the cost of smelting in the reverberatory that excess of flue-dust produced in blast-furnace smelting as compared with rever-

beratory smelting. The average milling cost at the Chino last year was 58½¢. per ton, so that it is evident that the field of milling and reverberatory smelting is likely to continue to make inroads into that of direct smelting. With so much as an introduction, I shall briefly describe each of the principal smelters in this district, without going into detail except as to such features as may be peculiar to that plant.

The El Paso Smelter

At El Paso the American Smelting & Refining Co. has recently added copper smelting equipment to a plant which has for years smelted lead ores. Two blast-furnaces, 40 by 144 in., smelt lump custom copper ore, derived from various parts of Arizona and New Mexico, yielding a matte of about 45% copper which is blown to blister in two Pierce-Smith converters; a newer 12-ft. Great Falls converter not yet having been put into service at the time of my visit. The main matte supply for the converter is derived from two 19 by 104-ft. reverberatory furnaces. These are oil-fired, but as this method of firing is general practice throughout the area it will not again be referred to except to give details of practice. Most of the oil used for firing is obtained from the Mexican fields, though Texas oil is also available, and has the advantage of not requiring as much preheating, as it is lighter in specific gravity. The reverberatory furnaces yield a 40% matte, the matte-fall amounting to about 30% of the charge, each furnace handling about 300 tons per day. The capacity is somewhat in excess of this, but was limited at the time of my visit by the capacity of the roasting plant. This consists of three 4-hearth Wedge furnaces, 22½ ft. outside diameter, and two more are in course of erection. These furnaces are designed to handle 100 tons each per day, but are being operated at a capacity of 130 to 150 tons each per day. It was originally expected that the average sulphur content of the Chino concentrate would not be so high as to

require much sulphur elimination, and that roasting of only part of the total tonnage would be required. In actual experience it was found that the sulphur content ranged between 12 and 22%, according to the part of the ore deposit from which the mill feed is obtained; the necessity of directing the steam-shovels so as to carry on development work in the most efficient manner, making it impracticable to control the mill feed. Running a Wedge furnace at so much in excess of its intended capacity makes it impossible to completely dry the concentrate upon the top hearth. It therefore passes through the slot upon the third hearth in a somewhat sticky state, and in order to cause it to pass freely it was necessary to remove the distributor plate. This causes the concentrate to pile up on the third hearth, and from time

expended in compressing it into a narrow and inconvenient site at the junction of Chase creek and the San Francisco river, the boilers for steam supply being scattered about in niches between other equipment. It is also unique as to its chimney, which consists of a shaft, or winze, to the top of the nearby mountain. The experiment is one not likely to be repeated, since such a chimney defies attempts to repair or enlarge it. A new plant has been designed by Repath & McGregor, under the direction of L. D. Ricketts, consulting engineer to the Company, and is already partly constructed, the site being farther down the San Francisco river, where ample dump room is available. The reverberatory furnaces will be 22 by 100 ft., space being provided for three such and for eight 21½-ft. Herreshoff roasters. This

BEDDING SYSTEM FOR COARSE ORE, CANANEA CONSOLIDATED COPPER CO.

to time coarse fragments roll between the central cylinder and the hearth ring, much to the disadvantage of the latter. Various small alterations have been made to minimize this and other minor troubles, but it is on the whole remarkable that a roasting furnace can be pushed so far beyond its designed capacity with comparatively little alteration beyond the use of an additional burner on the second hearth. This plant is under the direction of Kuno Doerr, general manager; J. J. Ormsbee, superintendent; H. F. Easter, assistant superintendent; and A. F. McCormack, assistant superintendent of the copper department.

Arizona Copper Smelter

The next smelting plant, proceeding to the west, is that of the Arizona Copper Co. at Clifton, Arizona. This is at the end of a rather long branch railway line, owned by the Company, which connects with the Union Pacific at Lordsburg, New Mexico. This is an old plant, shortly to be abandoned, which excites interest chiefly by the ingenuity which has been

plant is similar in its design to the new plant of the Calumet & Arizona, which will be described more fully later.

Leaching With Sulphuric Acid

An especially interesting feature of the work at the old plant is the leaching of oxidized copper ore with sulphuric acid. The acid, of 52°B. specific gravity, is made at the plant from pyrite obtained from one of the company's mines. The jig tailing from milling operations, containing 2 to 2½% copper, 0.4% S, 60% SiO₂, and 16% Al₂O₃, is charged into vats and leached for 12 hours, the solutions being so managed that the first strong solution contains very little free acid, and, after decanting, its copper content is precipitated by passing it through a trommel filled with scraps of wrought iron and steel. The precipitated solution then goes to waste, and the wash water used in the vats is strengthened by the addition of acid to yield fresh leaching solution. This method can only be used on ore which is

high as SiO_2 , otherwise the loss of acid through the formation of Al_2SO_4 and FeSO_4 becomes prohibitive. The acid consumed in leaching is given as $2\frac{1}{2}$ lb. per pound copper recovered. Allowing for the cost of the iron used for precipitation and labor there can be no great profit on the operation except as an adjunct to the wet concentration of ores of suitable composition. This Company is under the direction of Norman Carmichael.

The Shannon Plant

Just across the river from the new Arizona Copper plant is the mill and smelter of the Shannon Copper Co. This consists of two blast-furnaces 42 in. by 15 ft. and one 44 in. by 30 ft., the latter handling about 700 tons of charge per day. These furnaces are provided with cast steel crucibles, which have given trouble by cracking. Pyrite is brought from Gleason, Arizona, to yield the sulphur required for the formation of matte. About 500 tons per day of the ore-supply contains no sulphides and is smelted directly; the remainder, 300 tons per day, is concentrated 10 into 1. The fine concentrate is then dewatered and mixed with flue-dust before charging into the blast-furnaces. Two small stands of acid-lined converters are sufficient to handle all the matte produced. This plant is under the management of J. O. Bennie, who deserves the greatest credit for the skill with which he has brought into shape a rather unsatisfactory plant and a mine which is on the border line of profit. Mr. Bennie has carried on an extensive series of leaching experiments; the general method of attack being roasting in specially constructed heaps, the progress of the operation being so controlled as to completely convert the copper into the sulphate, and to avoid the formation of ferric sulphate, as this consumes iron in the subsequent precipitation of the copper. No details of results obtained have been released for publication, but the method seems to offer much of promise. The experimental work is exceedingly tedious, as the time required to build and burn the heaps is great.

The Detroit Smelter

At Morenci, a few miles to the west of Clifton, but at a considerably higher elevation, is the smelting plant of the Detroit Copper Mining Co. This presents a number of features of interest; for example, the smelting of concentrate in blast-furnaces. All the mine ore is milled and the only lump ore smelted is that produced by lessees. Smelting is now done in a 42 in. by 22-ft. blast-furnace, which is driven slowly, smelting 350 tons per day. The concentrate contains 15 to 17% copper and 15% SiO_2 ; about 50 tons per day of limestone is used as flux. The slag contains 7.2% Al_2O_3 and 2% MgO , and the matte, of which 60 to 70 tons per day is produced, contains 42% copper. It is thus seen that a high degree of desulphurization must be maintained. The tonnage to be handled is too small to justify building reverberatory furnaces. It is planned to build a 33-ft. furnace which will smelt even more slowly, the idea being not to increase the desulphurization, but to cut down the dust losses. It would seem, on the face of the matter, that this end might be better

obtained by first sintering the concentrate upon Dwight & Lloyd machines, but careful study of the local problems was made by the management, and it is safe to assume that the methods employed have only been adopted after due consideration. Converting is now done in acid-lined shells, but a Great Falls converter will perhaps be built, largely for the purpose of decreasing the amount of seconds to be rehanded. Another interesting feature of practice here is the use of Crossley and American Crossley gas engines for power supply. The gas is generated from bituminous coal, obtained from Dawson, New Mexico, in a Loomis generator. This is at the mine and the gas is brought to the smelter in pipes which sometimes give trouble in cold weather, due to freezing. The smelter is provided with round steel bins, which were built some years ago, and must be among the first bins of this type ever built. A. T. Thomson is manager of this plant, and E. W. Honeyman is superintendent.

The Old Dominion

The Old Dominion smelter, at Globe, is at the end of a 125-mile branch of the Southern Pacific, the Arizona Eastern, which connects with the main line at Bowie. At this smelting plant there are six blast-furnaces, of which three or four are usually in use. All, except one, are 48 in. by $16\frac{1}{2}$ ft., the exception being $19\frac{1}{4}$ ft. long. An average daily tonnage of 325 per furnace is smelted. The smelting column is about 12 ft. high and 22 oz. blast pressure is used, with a coke percentage of 12.6. These features are due to the shortage of sulphur on the smelting charge, it being necessary to bring sulphide ore from Bisbee to make up the deficiency. The flue-dust made amounts to about $8\frac{1}{2}\%$ of the tonnage smelted; this is drawn from the chambers and shipped to Douglas for smelting in the reverberatory furnaces. The matte averages 44% Cu and is handled by an 8-ft. Great Falls converter. This type of converter has become standard in the district, as its form, a vertical cylinder, offers obvious mechanical advantages over the horizontal cylinder of the Pierce-Smith converter. Since the basic lining is expected to maintain itself over a long period it should be of such a shape as to offer the maximum of strength with the minimum of exposed surface. Part of the tonnage smelted at this plant is lump ore, and part concentrate; about 500 tons of ore per day being concentrated 4 into 1. The relative proportion of concentrate to lump ore in the furnace is 1 to 4. P. G. Beckett is manager and L. O. Howard smelter superintendent.

The Miami District

A short distance to the west the Miami is milling all its ore and shipping its concentrate over 200 miles, to Cananea. The Miami ore is also short of sulphur and the Old Dominion company, which has been involved in litigation for many years, apparently does not care to undertake the construction of a reverberatory plant for the handling of custom ore. As within a comparatively short time the Inspiration, which adjoins the Miami, expects to be producing concentrate from an 8000-ton mill, the International

Smelting & Refining Co. will shortly undertake the construction of a new smelter at Burch, halfway between Globe and Miami to consist of roasting and reverberatory smelting equipment.

The Hayden Plant

About 20 miles directly south, but across a range

CONVERTER STAND, CALUMET & ARIZONA SMELTER.

of mountains, is the Hayden smelter of the A. S. & R. Co. This was recently built to handle the concentrate from the Ray Consolidated Copper Co., which it directly adjoins. The wet concentrate brought in railway ears, is allowed to dry as much as possible, then is sampled, dropped into bins, and when wanted for smelting is drawn out upon belts, which discharge into the McDougall roasters. Of these, five are 24-ft. and have 5 hearths, and three are 19-ft. and are 6-hearth furnaces. The concentrate contains 24% sulphur, and it is necessary to burn a little oil from time to time, on account of the high moisture. Each McDougall handles about 90 tons, the top of one 5-hearth roaster being used for drying. The reverberatory furnaces are 19 by 112 ft., and smelt about 350 tons per day each, including seconds, with a consumption of 0.8 to 0.9 bbl. oil per ton smelted. The steam recovered in the waste-heat boilers (Stirling) goes to the main power-plant, and suffices to meet all the power requirements of the smelter with a substantial success. The matte-fall amounts to about 25 to 40% matte. This is blown to blister in either one of two Pierce-Smith converters or in one 12-ft. Great Falls type converter. Slime concentrate is used for fettling the furnace. The blister is poured into an oil-fired receiving vessel in order to keep it hot while pouring the anodes. This smelter would naturally be the one for handling the Miami and Inspiration concentrate, but

in order to get over the intervening short distance, several hundred miles of railway haul would be necessary. A short line connecting Winkelman with a point on the line from Bowie to Globe would form a short and convenient connection, but as the line would have to traverse the site reserved for a dam in a future government reclamation project there is but little likelihood that it will ever be built. J. B. Haggie is superintendent of this plant.

Calumet & Arizona Smelter

At Douglas, which is on the border line between the United States and Mexico, there are two smelting plants. The new plant of the Calumet & Arizona, which was designed by Repath & McGregor under the direction of J. C. Greenway and L. D. Ricketts, embodies all the important features of the New Arizona Copper Co. smelter and also that of the United Verde, at Jerome, therefore, I shall describe it at some length. The blast-furnaces, of which there are two, are 48 in. by 40 ft. and are designed for the maximum convenience in charging and tapping. The ore from the beds is drawn out upon a series of belts, which in turn discharge upon a main belt which

elevates the ore, fuel, and flux to the bins above the blast-furnaces. Each furnace is provided with four charging ears, each 20 ft. long, which rest upon track scales beneath charging hoppers, which are filled by

AUTOMATIC COPPER INGOT MOLD, COPPER QUEEN SMELTER.

belts provided with distributors, running between the pairs of hoppers. When the charge-car is filled, it only requires to be moved a short distance forward in order to discharge directly into the furnaces. The estimated capacity of these furnaces is 800 tons each per day. The settlers are oval in shape, the matte being tapped directly into pots set in the main crane aisle, the slag being drawn off into large pots

and hauled by an electric locomotive to the slag dump. The reverberatory furnaces, of which there are four, with space for a fifth, are 19 by 100 ft., and present no special features beyond the convenience of their arrangement with respect to the rest of the plant. The calcine is brought directly over the charge hoppers in cars from the roaster. The converter slag is poured by the crane directly in at the feed end, and fettling and fluxing material, brought up by the same belt which elevates the lump ore, is drawn about as desired in small cars. Of converters, six stands of 12-ft. Great Falls type are provided.

Arrangement of Plant

The converter flue is hung directly upon the frame of the building and a hopper for the silicious addition is placed directly above, delivering the silicious material directly through a chute into the converter, without its being necessary to move the shell from its normal blowing position. These bins are filled by a conveyor, thus relieving the crane of much work, so that one is able to serve the whole main aisle. Two casting machines of the Anaconda type will be provided, one at each end of the main aisle. In order to eliminate labor in breaking up skulls, a heavy steel plate with 8-in. holes is placed beneath a miniature pile-driver; as fast as the material is sufficiently reduced in size it falls through the plate into a hopper below. For roasting concentrate, twelve 21½-ft. Herreshoff air-cooled roasters are provided. These have six hearths and the roof is also used for preliminary drying. These as well as the furnaces are provided with dust flues hung in a steel frame, and with bottoms made from hollow tile. As this tile is manufactured at El Paso, steel plates will be substituted for it at Jerome, on account of the relative freight cost. The gases are distributed throughout the settling chamber by a row of flat bands, hung near the entrance; by sliding these the gases can be uniformly distributed over the whole cross-section. At the middle of the dust chamber a 20-ft. section is hung with No. 10 wires suspended from the roof. The plant has been designed to secure a maximum of capacity with a minimum of labor and equipment, thereby attaining low operating costs. The success of such an arrangement is largely dependent upon an accurate foreknowledge of the conditions to be met, and the whole forms an excellent example of advanced modern practice. J. C. Greenway is manager.

Copper Queen Smelter

The other plant at Douglas is that of the Copper Queen company, built about ten years ago, and exhibiting characteristic differences from the plant just described. The most marked of these is in the bedding system employed. Long stalls, 21 car lengths long and 50 ft. wide are provided, with tracks upon the bottom for reclaiming, and tracks at a higher elevation on each side. Converter slag is placed on the bottom, lump ore is distributed over the top, and a small amount of concentrate is intermixed. About two days after a bed is completed, reclaiming of it is begun, using small steam-shovels for the purpose. The total storage capacity is 100,000

tons. The cost of reclaiming is given as 3c. per ton, 9 days being required to exhaust a bed. This ore is smelted in ten blast-furnaces, five of which are 20 ft. long and the others 18. The larger furnaces smelt about 360 tons per day each, using 30 oz. blast pressure, and making a 40% matte. The smelting charge is rather high in alumina, yielding a somewhat viscous slag.

The flue-dust and roasted concentrate from the Nacozari mines is smelted in two reverberatory furnaces, 19 by 95 ft., which handle about 300 tons per day each, using 0.86 bbl. of California crude oil per ton smelted. This plant is unusual in that Erie boilers, instead of the usual Stirling, are used to recover the waste heat of the reverberatories. As the result of extended experience the mechanical engineer of the plant reports that these boilers are of almost equal efficiency, lower first cost, and are easier to clean. The usual difficulty experienced with the Erie boiler is that it primes badly when it is forced, and a waste-heat boiler usually works under a heavy overload. The draft pressure on one reverberatory is 0.5 in. and on the other 0.3 in., the difference being due to a fuel economizer placed after the waste-heat boiler in the second. Better results are obtained with a higher draft pressure, but may be due in part at least to the fact that this furnace has been in operation for a longer period. It was necessary to raise the roof of these furnaces in order to give more combustion space, and it may be expected therefore that the 22-ft. reverberatory at the New Arizona Copper Co. plant will give somewhat better results than a narrower furnace. The necessity for ample space to ensure the proper combustion of a liquid fuel has been discussed at some length in recent issues of the *Mining and Scientific Press* and need not be further referred to here. This plant is under the general direction of Walter Douglas. Mr. French is manager, and Frank Rutherford superintendent.

Practice at Cananea

The smelting plant at Cananea, a short distance south of the Mexican border, may be regarded as the type of the district, since it is here, under the direction of L. D. Ricketts, that the methods and equipment have been developed which are embodied in the newer plants now under construction or recently completed. The lump ore is smelted in eight blast-furnaces, 48 by 210 in., with a height of charge above the tuyeres of 7 ft. and using 26 oz. blast pressure. Each furnace smelts about 300 tons per day, using 9% of coke, and yield flue-dust amounting to about 10% of the charge. The material charged to these furnaces consists of lump ore, some custom ore, converter slag, and about two-thirds of the total amount of concentrate made in the Cananea mills, 600 tons per day in all. The charge is delivered into bins placed above the charge floor, and is run directly into the furnaces through chutes. The system of bedding for mixing the charge has been described in detail by M. J. Elsing, and will not be further referred to here.

The Cananea concentrate carries 30 to 35% sulphur and is roasted in 6-hearth 18-ft. McDougall furnaces, 10 being provided and 6 in use. The sul-

phur content is reduced to 6 to 7%, each roaster handling about 40 tons per day. The calcine and about 75 tons per day of raw Miami concentrate are smelted in two 19 by 100-ft. reverberatory furnaces which handle 260 to 275 tons per day each. The fuel used is California crude oil, less than 0.8 bbl. per ton smelted being required, having been reduced to that figure from 0.9 bbl. The oil is heated by a steam coil in a tank and is injected by air at 13 lb. pressure, the former burners which used both air and steam for injection having been discarded. Air for combustion is admitted through a checkerwork of brick above the burners, this arrangement producing a more even distribution of heat throughout the furnace. The Miami concentrate, still wet, is dropped against the walls to serve as fettling, and is better for this purpose than silicious ore, which is likely to produce 'floaters.' This concentrate only carries about 21% S in its raw state.

Miami Concentrate

The remainder of the Miami concentrate, which amounts to 125 tons per day in all, is blown into the converters by use of an ingenious blow-pipe. Three 12-ft. Great Falls converters are in use, and three more are under construction. The matte to be handled amounts to 400 to 500 tons per day, yielding about 150 tons of blister copper. The concentrate is first dried and in the course of the blow a certain amount of it is blown through the tuyeres, one at a time, in order to prevent local chilling. In this way 50 tons per day of concentrate is smelted, its silica content serving to displace a corresponding amount of silicious material which would otherwise require to be introduced through the mouth. The two reverberatories are provided with eight waste-heat boilers, three being 250 hp. each, two 225 hp., and three 200 hp. These yield about 1000 hp., the remainder of the power being furnished by a battery of oil-fired boilers. With admirable foresight the tailing from the milling plant has been impounded behind sand dams, looking forward to a time when it will be possible to recover a further part of its copper content.

At Jerome is the smelting plant of the United Verde. The old plant is just in process of being abandoned and a new plant is under construction. This will not differ materially from the new Calumet & Arizona plant, except that Wedge furnaces will be used for roasting. At Humboldt is the smelting plant of the Consolidated Arizona. This consists of blast and reverberatory furnaces, only part of the equipment now in use. I have not seen this plant, the management having declined to extend that courtesy. An important project which has not yet reached the construction stage is the Ajo or New Cornelia property, which has been acquired by the Calumet & Arizona, after extensive drilling operations had disclosed the existence of large reserves of oxidized ore. Plans for working have not yet been fully matured, but it has been proposed to leach the ore with sulphuric acid. The resulting copper sulphate solution will be precipitated by the metallic iron. The manufacture of sulphuric acid is rather expensive, however, and the consumption of iron so high that even with cheap iron the process

is likely to be somewhat expensive. The process is being studied with care.

Summary

The range of ore to be handled in this district may be indicated on the one hand by the Cananea blast-furnace practice, with the elimination of 70% of the sulphur in the charge and the production of a 33% matte, and the Miami concentrate, which contains about 35% copper and 21% sulphur. The tendency toward increasing use of reverberatory smelting is not only due to the increasing amount of fine concentrate to be handled, but also because many of the lower-grade deposits are too low in sulphur for the formation of a satisfactory matte. The net cost of reverberatory smelting has been lowered to a point where, in many cases, it is better at once to smelt in reverberatory furnaces, rather than to attempt to handle much concentrate in the blast-furnaces, with the inevitable rehandling of a considerable part of it as flue-dust. For roasting, both the water-cooled Wedge furnace and the air-cooled Herreshoff are coming into use, as more satisfactory from a mechanical standpoint than the ordinary McDougall. The Great Falls type of converter has become standard practice, the longer life of the basic lining leading to lower costs, especially through the greatly decreased handling of seconds. Thus at Cananea it is hoped that much of the converter slag can be poured directly into the settlers of the blast-furnace, instead of requiring smelting. Sweeping changes in present practice are likely to result from the experimental work now being done on the use of flotation for the recovery of concentrate and of leaching processes for the recovery of copper. But through the similarity of general conditions which govern smelting operations in the territory which has been described, it is likely that smelting practice in the area will continue to exhibit certain characteristic common features.

The suggestion was made recently to the Queensland Minister of Mines, Mr. Appel, that the Government should advance \$290,000 for the purpose of sinking a large shaft on the Charters Towers goldfield to test the ground to a depth of 4000 ft. The minister replied that the Government did not consider the scheme feasible, for the present at any rate. Mr. Appel, however, stated that the Brilliant Block Co. had made an application for a loan of \$12,000 to carry out the exploratory work mentioned as desirable before the shaft was sunk. The Government had previously advanced \$14,400 for this work, to be undertaken by the Brilliant Block and Brilliant Deeps jointly, and the amount had been so useful that it was desired to continue the arrangement, the sum of \$12,000 being required for its completion. The July metal production of the field was valued at \$115,000.

The Lena Goldfields, Ltd., in Siberia, during the season from October 1, 1912, to July 10, 1913, mined and hoisted 549,384 cu. yd. of gravel, washed 456,218 cu. yd., and recovered gold worth \$3,216,000. The Orsk Goldfields, Ltd., in July dredged 116,080 cu. yd., yielding \$49,000.

Dredging in Victoria in 1912

*There were 138 leases covering an area of 14,797 acres of land, in seven different districts of this state in Australia, during the year, and 94 plants were working and 12 in course of building or reconstruction.

Scale of Operations

Fifty five bucket-dredges, working an aggregate period of 2104 weeks, raised 16,777,591 cu. yd. of material, yielding 59,445 oz. of gold, or 1.7 gr. per cubic yard; $3\frac{3}{4}$ tons of tin, valued at \$2400, was also recovered. The area treated was 589 acres, and the quantity of gold saved per acre was 100.9 oz. The dredges, which treated most of the material, recovered 1233 oz. in 52 weeks from $20\frac{1}{2}$ acres of ground, averaging 1.2 gr. of gold per cubic yard of material treated. The average weekly return of gold per plant was 28.2 oz., the number of men employed was 765, and the weekly expenses in wages, fuel, water, maintenance, and repairs per plant averaged about \$360, equivalent to, say, 19 oz. of gold. One bucket-dredge treated over 15,000 cu. yd. of material per week. Another handled more than 14,000 cu. yd. per week; and three others treated over 13,000 cu. yd. weekly.

This system shows a decrease of gold won during the year of 53 oz. as compared with the previous year, and a decrease in dividends of \$76,000. Sixteen companies paid dividends ranging from \$480 to \$28,800, from ground yielding 1.2 to 4 gr. per cubic yard of material treated; but it is to be noted that a good many companies working their plants are practically paying for them out of the gold recovered, dividends thereby being reduced. The amount expended by the dredging companies in wages, fuel, and maintenance during 1912 was \$768,000, and the dividends paid \$14,400. The initial cost of these plants was \$1,400,000. The sizes of buckets varies from 3 to 6.5 cu. ft., and from 10 to 16 are discharged per minute.

Hydraulic Sluicing Plants

Twenty-six pump hydraulic-sluicing plants, during an aggregate working time of $386\frac{1}{2}$ weeks, handled 2,445,009 cu. yd. of material, yielding 11,147 oz. of gold, or 2.2 gr. per cubic yard. Twelve and one-half tons of tin, valued at \$7700, was also won. The area worked was 69.8 acres, the quantity of gold won per acre being 159.7 oz. The plant with the highest yield of gold obtained 1226 oz., from $6\frac{1}{2}$ acres of ground, containing 167,794 cu. yd. of material, or an average of 3.5 gr. per cubic yard. The average weekly yield of gold per plant was 29.1 oz., and the number of men employed was 407. The average weekly expenditure in wages, fuel, water, and repairs, per plant, while sluicing, shifting, and repairing, was \$430, equal to about 22.6 oz. of gold. One pump sluice plant operated on over 15,000 cu. yd. of material per week, another plant of the same type treated over 14,000 cu. yd. per week, two others each treated over 7000 cu. yd.,

and three others each did over 6000 cu. yd. in the same period. As compared with the previous year, a decrease of 5880 oz. of gold is shown by this type of dredge during 1912, also a decrease of \$7200 in dividends. The dividends paid by the companies varied from \$770 to \$3400, obtained from ground worth 2.9 to 5.5 gr. per cubic yard of overburden and wash-dirt treated. An increase of 10.65 tons in the tin yield is shown. The wages, fuel, water, and maintenance accounts total \$240,000, and the dividends paid were \$7700. The initial cost of these plants was \$326,000.

Twelve jet elevators, working an aggregate time of 147 weeks, handled 407,265 cu. yd., yielding 2620 oz. or 3 gr. of gold per cubic yard of material treated. The area worked was 13.7 acres, the quantity of gold won per acre being 191.3 oz. These plants employed 70 men, and were valued at \$31,200. Other plants of this description were in operation during the year, whereby 793 oz. of gold was recovered, but other information is not available.

Summary of Placer Mining During 1912

The total quantity of material treated during the year, under dredge mining and hydraulic sluicing by gravitation, was 19,722,227 cu. yd., as against 20,144,347 cu. yd. in 1911, and the amount of gold won was 73,781 oz. as against 81,593 oz. in 1911. The yield of gold per cubic yard of material treated was 1.8 as against 1.94 gr. for the previous year. The total area treated was 675.7 acres, the ground varying from 8 to 59 ft. in depth, and the number of men employed was 1293. This area may be classified thus: agricultural, 20 acres; pastoral, 159 acres; river and creek beds and old worked ground, 497 acres. Under this heading the dividends paid were \$153,000. The wages and other expenses amounted to \$1,066,000, and the initial cost of the plants was \$1,872,000. The quantity of tin won during the year was 20.6 tons, valued at \$12,000.

Since 1900, placer mining has treated 185,254,860 cu. yd., yielding 856,256 oz. gold, an average of 2.2 gr. per cubic yard. Other returns bring this total to 951,944 oz., and 355.5 tons of tin.

The iron and steel output of Italy for the past year has been somewhat disappointing, although a general increase is to be noted. The iron is produced almost entirely from the ore from the Elba mines, the importation of foreign ores amounting to only 30,000 tons. While the national production is increasing, the importations of crude iron are also on the increase. In 1912 there was 267,000 tons imported. The country produces a million tons of iron and steel, and imports 300,000 tons of girders, sheet iron, etc., in addition to 400,000 tons of scrap iron for the Martin steel furnaces.

Extensive asbestos deposits are being worked on the eastern slope of the Urals. The production of the region has doubled during the past five years. The production for 1912 amounted to 1,007,697 poods, and the total production for the past ten years, 6,365,004 poods, or approximately 106,000 long tons.

*Abstract from the annual report of the government on dredge mining and hydraulic sluicing.

Origin of Lead, Zinc, and Silver in the Cœur d'Alene—II

By OSCAR H. HERSHEY

The Belt sediments, in northern Idaho and western Montana, have been invaded by a number of small stocks of monzonite, syenite, granodiorite, and closely related rocks. Those in the Cœur d'Alene district are presumed to be arms of a deep-lying north extension of the great quartz-monzonite batholith of central Idaho. About some of these arms there are definite zones of contact metamorphism.

Prichard Type of Ore Deposits

The Prichard type of ore deposits invades these zones, in a few cases to the very contact. The mineralogical character of the deposits is like that of the ordinary Prichard plus contact metamorphic silicates. The best example of these contact metamorphic ore deposits is at the Granite mine on the border of the Gem monzonite area. Mr. Ransome says¹⁴ that "the association of the ore minerals with the metamorphic silicates is so close that the conclusion of their contemporaneous genesis is unquestionable. . . . The foregoing characteristics indicate that the ore of the Granite mine was deposited shortly after the intrusion of the monzonite and is a phase of contact metamorphism." In proceeding eastward away from the Gem monzonite there is a gradual fading of the evidences of metamorphism. Garnet and green biotite are intergrown with the sulphides in the Gem vein. Green biotite and an asbestiform mineral occur with the sulphides in the Hercules orebody. The ores of the Granite and Sixteen-to-One mines, in the contact zone, are rich in sphalerite. This mineral decreases, in the Canyon Creek mines, away from the monzonite area and upward in the veins. Magnetite and pyrrhotite are present near the contact, but seemingly decrease and finally disappear entirely away from the monzonite.

Wardner Type of Ore

After leaving Canyon Creek district, by selection without reference to distance from the monzonite at Gem, a mineralogical gradation may be found to what has been denominated the 'Wardner type' of ore. I suppose this refers to an ore that consists of quartzite fragments, siderite, galena, a little vein quartz, and practically no pyrite and sphalerite—the 'Bunker Hill type' of my classification. The magmatic hypothesis presumes that the ore minerals in the contact metamorphic deposits were derived from the monzonite and that as there is an apparent mineralogical gradation between all the ore deposits of the Cœur d'Alene district, it is reasonable to presume that they have all been derived from the same source and by the same process, their differences being largely a function of distance from the monzonite contact. It is supposed that when the solutions issued from the monzonite, zinc sulphide was at first deposited in equal or even greater quantities than lead sulphide. Siderite was driven to a con-

siderable distance from the contact. Thus the Prichard type must owe its characteristics to proximity to the monzonite. It is held that because ores in which pyrrhotite and sphalerite are comparatively abundant occur in the Pine Creek prospects, the top of the batholith may not be very deeply buried in that region. The fact that the Prichard type is confined to the Prichard formation may be explained, under this hypothesis, as due to the Prichard being stratigraphically the lowest formation in the mining districts, and it would hence be most likely to receive the deposits nearest to the monzonite. The fact that the monzonite is intruded into rocks as high as the Wallace raises no difficulty, for there are no contact ore deposits higher than the lower Burke so far as I know. It may, therefore, be purely a coincidence that the Prichard type is confined to the Prichard rocks.

Relation of Batholith to Ore Deposits

The magma at first, it is supposed, had very small quantities (per ton) of lead and zinc, and hence it is not surprising to find the arms of the batholith which reach the present surface practically barren of these metals. The millions of tons of lead and zinc in the district were apparently not supplied by these arms. As the upper portions of the batholith cooled and crystallized, it is presumed that there was a concentration of the heavy metals in the remaining portion. Finally, the process of crystallization expelled from the deep-seated portions of the magma solutions relatively rich in zinc and lead. They rose through the thick shell of solidified monzonite, either in fissures or through the minute pores of the rock. In either case they would hardly have left no traces in the monzonite. So far as I know, no such traces are known in the exposed monzonite. It is, therefore, presumed that the solutions entered the sediments from the monzonite at points deeply buried beneath the present surface. Unfortunately, the mines may never penetrate to where the mineral deposits in the sediments may be presumed to connect with some sort of mineralization in the igneous rock, so the magmatic hypothesis is under the disadvantage that it may never be capable of positive proof in the field.

Contact Deposits

The contact metamorphic ore deposits are incontrovertible proof that some zinc and lead were deposited from solution in connection with the monzonite intrusion, but they are not even strong evidence that the metals came from the magma. Practically all those known to me occur near the top of the Prichard formation, suggesting that the magmatic gases or waters, or vapors heated by proximity to the eruptive rock, leached them from diffused mineralization at this horizon. At a certain mine in western Montana, typical contact ores have been deposited in connection with a nearly vertical fissure

¹⁴Professional Paper 62, U. S. Geol. Surv., p. 185.

cutting Prichard strata dipping about 30°. Bands that are predominantly slate alternate with bands that are predominantly quartzitic. The horizon is near the top of the Prichard formation. The minerals present are chlorite, garnet, actinolite, pyrrhotite, chalcopyrite, galena, sphalerite, pyrite, quartz, and calcite. The shoots of ore apparently pitch in the direction of the dip of the strata. That portion of the vein that lies deepest stratigraphically, has shoots that are mainly zinc ore. Higher stratigraphically are shoots that contain much lead ore and proportionately less zinc. There is no evident explanation for this in the apparent character of the wall rock, in the associated metamorphic minerals and in the relative altitudes. I have considered it evidence that zinc greatly predominates in the supposed diffused deposits at lower stratigraphic horizons and the lead content increases higher; but perhaps I have made unwarranted use of this case, particularly as the exact situation of the eruptive is not known.

The Granite Mine

At the Granite mine, the ore occurs in irregular masses which are practically confined to the Prichard sediments. The adjacent monzonite is barren in appearance and contains small aplitic and pegmatitic dikes which, so far as I could see in a surface examination, are absolutely barren. "The commonly accepted theory of the origin of aplite is that it represents the acidic remainder in a granite or quartz diorite magma after the more basic elements have crystallized. The aplite is forced up from below and fills previously formed cracks, which are perhaps the result of cooling, in the main mass of the granitoid rock."¹⁵ It seems to me that there is here evidence that long after the Gem monzonite arm had crystallized, at least in its upper portion, the emanations from the deep-seated portions of the magma did not bear notable amounts of lead and zinc. At the Granite mine, I have seen small pockets of sphalerite in the monzonite near the border; I am not certain whether they occur as inclusions or have been deposited later than the igneous rock. Streaks, several inches thick, of nearly solid galena lie against a wall of monzonite. I strongly suspect that the ore deposits were in existence in some form before the intrusion.

There is reason to consider it possible that in time conclusive proof may be secured that a large part of the lead and zinc mineralization in the Coeur d'Alene district antedated the monzonite intrusion. The exact relation between the fault systems and the intrusion has not been worked out. Immediately west of the southern portion of the Gem area there is a badly faulted area containing some comparatively old faults. Unfortunately, its relation to the monzonite is obscured by a great fault, the Dobson Pass, at the contact. The east side of the Gem area seems more promising. When this has been thoroughly studied it may be found that much of the ore is genetically connected with faults that are older

than monzonite. This surmise is warranted by the outlines of the various monzonite areas. I am inclined to the opinion now that in my Wardner paper I put the monzonite intrusion too far back. I thought I saw evidence of it in certain possible contact deposits, and in the disseminated zinc-lead mineralization, making it older than the second system of faults. These deposits, however, may be due to an earlier intrusion or to some other cause. About all that is positively known as to the age of the monzonite is that it antedated the ninth system faulting.

The Wardner district contains, perhaps, the strongest evidence in support of the magmatic hypothesis. When the four principal stages of lead deposition (the disseminated zinc-lead mineralization and the Blue Bird, Jersey, and Bunker Hill stages), are considered, it will be seen that there has been a tendency to a gradual elimination of the zinc and iron sulphides. A similar mineralogical change in the Canyon Creek mines has been attributed by Mr. Ransome to the effect of increasing distance from the monzonite and by me as brought about by increasing distance from the presumed source of the minerals in diffused mineralization in the Prichard formation. In the Wardner district, however, it is a function of time, not of depth. Under the magmatic hypothesis it might be explained as the result of a receding source, the solutions in each stage starting at a much greater depth as the result of the progressive solidification of the magma. Unfortunately, the same effect in so far as it is influenced by heat and pressure might be secured by the progressive decrease of depth due to lowering of the surface of the country by erosion, so that it furnishes no real support to the magmatic hypothesis. Besides, there were temporary returns to the zincy status. The very latest ore mineralization in the district has nearly as much zinc as lead. The silver ratio increased to the Jersey stage, but in the Bunker Hill type dropped to normal, namely, a little less than half an ounce for each per cent lead.

Mississippi Basin v. Coeur d'Alene Deposits

I want to call attention to a curious contrast in one particular between the lead and zinc deposits of the Mississippi Basin districts and those of the Coeur d'Alene. In the former districts zinc tends to predominate at lower levels, which is explained as due to the fact that downward-moving waters, owing to the principle that zinc has a less strong affinity for sulphur than has lead, may concentrate the galena at high levels and the sphalerite at lower levels. In the Coeur d'Alene, on the contrary, a similar tendency for zinc sulphide to predominate at lower levels is attributed to the action of ascending waters. In the Mississippi Valley districts, the lead and zinc traveled largely as sulphates and were precipitated by the agency of organic matter. The same principle, applied to the supposed diffused mineralization in the carbonaceous Prichard slate, would lead one to expect lead to predominate over zinc. However, through the law of mass action, if zinc salts greatly predominated in the Prichard water-body, more zinc than lead might have been deposited. In the case of the ore-making solutions it is not so

¹⁵Weed, W. H., 'Geology and Ore Deposits of the Butte District, Montana,' Prof. Paper 74, U. S. Geol. Surv., p. 39, 1912.

easy to get around this difficulty. The solutions appear to have started in the Prichard formation (or near the monzonite) comparatively rich in zinc. For a time they lost zinc faster than lead. Because of its stronger affinity for sulphur and less solubility, lead sulphide should have been precipitated first and should be more abundant at lower levels. If the mineralogical character of the Prichard type be attributed solely to the precipitating effect of the slaty rock, the carbon marks the only important mineralogical difference between this rock and the higher rocks, and this carbon should have made galena more abundant at lower levels than higher. My impression is that the explanation will lie along the lines that the minerals in the Coeur d'Alene were carried as sulphides dissolved in hot water under pressure and precipitated by decrease of heat and pressure. I have not been able to find any chemical law which will permit zinc sulphide to be precipitated in preference to lead sulphide, nor have I found any very definite statement as to the behavior of dissolved sulphides under considerable heat and pressure.

Copper and Gold Minerals

If there are any mineral deposits in the Coeur d'Alene district that derive their metals from the monzonite magma, they are more likely to be the copper and gold than the lead and zinc deposits. In central Idaho, where erosion has cut deep into the quartz-monzonite batholith, some idea of what minerals may be traced to the deep-seated portions of the batholith may be obtained. The Geologic Map of North America¹⁶ shows a broad expanse of 'post-Cambrian intrusives' in central Idaho. A large part of this area is quartz-monzonite. Turning to plate VII, in Bulletin 507, U. S. Geol. Surv.,¹⁷ it will be found that this area is studded with districts in which gold is predominant, a few with silver predominant, and none with lead predominant. From this it seems proper to infer that gold would be, by value, an important constituent of any mineral deposit derived from the deep-seated portions of the batholith. The silver-lead deposits of the Wood River region, near Hailey, in Blaine county, Idaho, are cited as supporting the magmatic origin of the Coeur d'Alene deposits, because they occur in sediments on the flanks of the great central Idaho granitic area, because these sediments are intruded by granite or quartz-monzonite masses, because siderite is abundant, and because of metasomatism in the ore deposits and its weakness in the country rock. I have not seen the Wood River deposits, but I see nothing in the descriptions that precludes the probability that the lead was derived from the sediments.

The copper deposits at Butte, Montana, occur in the Boulder batholith of quartz-monzonite. "Similar batholiths of granite occur elsewhere in the Montana ranges and are all probably connected with a deep-seated parent mass that underlies the entire region between the Front range and the Idaho

plains."¹⁸ This, by inference, connects the mass at Butte with the monzonite in the Coeur d'Alene region. Pyrite "occurs as a primary constituent of the Butte quartz monzonite and in pegmatitic facies of the aplite." In massive veinlets it carries some copper and "is supposed to be the mother copper mineral of the district." Mr. Weed also states that "chalcopyrite is a primary mineral in the Butte quartz monzonite, a study of thin sections and of polished specimens showing that it is intergrown with the rock minerals in the perfectly fresh rock." The earliest copper veins are a mass of pyrite and quartz carrying less than 1% of copper. "Though the evidence is not conclusive, it is believed to indicate that the copper and other metals of the quartz-pyrite veins are derived from magmatic emanations coming from a deep-seated mass of igneous magma." I am not disposed to criticize that conclusion. The gold in the Butte copper ore averages low, but is much greater than in the Coeur d'Alene lead ore.

Occurrence of Gold in the Coeur d'Alene

In the latter district, gold veins occur mainly in two groups, both of which are rather low in the Prichard formation, suggesting that minute quantities of gold may have been disseminated in the lower Prichard strata, but I am inclined to connect them with the monzonite intrusion. Nearly all the gold-quartz veins in the Murray district that have been described¹⁹ are bed veins and lie at rather low dips. They contain small quantities of pyrite, chalcopyrite, galena, sphalerite, and free gold. They may all be connected with the so-called 'Mother vein.' This is a large low-grade base vein traversing the district in a northwest direction and extending, if I may believe prospectors, six or seven miles. It stands nearly vertical and cuts the bedding of the Prichard rocks. Where seen by me it is 15 to 30 ft. wide, largely composed of quartz, heavy with pyrite. In places considerable chalcopyrite and galena appear with the pyrite. The entire vein is said to carry appreciable but small amounts of gold. This great vein may well extend down to the supposed underlying monzonite. The presence of scheelite in one of the gold quartz veins may be another indication of derivation from a magma, for tungsten deposits are almost invariably found in or near a granitic batholith. As Mr. Ransome points out, "although the gold-quartz veins all carry a little galena, yet the striking feature about them is not their similarity to the lead-silver deposits, but their rather marked difference in structure and in mineralogical character. No deposit has been found, so far as known, which suggests any transition between gold-quartz veins of the Murray type and lead-silver deposits such as those of the Barton and Paragon mines in the same (Prichard) formation." A typical Prichard type vein, the Terrible Edith, occurs near the principal old gold-quartz mine, but a little higher, altitudinally and stratigraphically. The foreman says that the ore on the middle level contained \$2 gold

¹⁶Prof. Paper 71, U. S. Geol. Surv., plate 1, 1911.

¹⁷Hill, J. M., 'The Mining Districts of the Western United States,' 1912.

¹⁸Weed, W. H., 'Geology and Ore Deposits of the Butte District, Montana,' Prof. Paper 74, U. S. Geol. Surv., p. 28, 1912.

¹⁹Prof. Paper 62, U. S. Geol. Surv., pp. 141-149.

per ton, as paid for by smelting companies. This indicates that the Terrible Edith solutions came into contact with a gold-quartz vein and that the Prichard type of lead-zinc deposits is younger than the Murray gold veins. I have no intention of committing myself to the idea of a magmatic origin for the gold, but I submit that the gold veins are of the type that would be expected if derived from the deep-seated portions of the great quartz-monzonite batholith, and the lead and zinc veins are not.

The copper veins in the Coeur d'Alene are of two types. In one, the primary mineralization was pyrite and chalcopyrite impregnating certain porous bands of quartzite. These veins are parallel to the bedding. The other type consists of quartz veins with occasional pockets of chalcopyrite. There is usually some pyrite and in some veins considerable galena. These veins cut the bedding. They appear to be more independent of the formations than are the lead veins properly so called, and as numerous in Wallace areas as in Prichard. They are also more independent of the excessive disturbance of the rocks. From this fact, and their mineralogical composition, they appear to me more likely to be genetically connected with monzonite that may be presumed to underlie the entire district than are the lead-zinc veins. The galena present in some of the copper veins may have come from the magma or may have been leached from the sediments by the ascending solutions. Even the copper-impregnated bands may have derived their minerals from solutions emanating from the magma. Some of the copper veins have little gold, while others contain \$2 to \$3 per ton. The silver content varies from nearly nothing up to 10 to 15 oz. per ton.

Silver-Bearing Lead Ore

In the lead mines of the Coeur d'Alene, when the silver ratio exceeds 0.5 oz. to each per cent lead, the excess is nearly always due to the presence of argentiferous tetrahedrite. This mineral appears to be distributed somewhat independent of the lead and occurs, with chalcopyrite and small quantities of sphalerite, in bodies of siderite and pyrite that contain no lead. Without committing myself to the theory, I say that this argentiferous tetrahedrite may have been derived from the monzonite magma.

In a territory about one and one-half by two miles, in the range east of the Steptoe Valley smelter at McGill, White Pine county, Nevada, there is a group of small lead mines that have produced some shipping ore. At the time of my visit in 1905, I estimated that there was about 12 tons of shipping ore in sight, but the character of the deposits is such that no large reserves would be carried. Small pockets (up to 1000 lb. weight) of rather coarse-grained galena are irregularly distributed through Lower Cambrian limestone, without any apparent connection with deep-extending fissures, though they are largely associated with secondary calcite in veins and irregular bodies. This is the only district in eastern Nevada that I have visited in which lead ore occurs under the conditions common to the great lead districts of the Mississippi Valley. I was told that the ore contains almost no silver or gold.

In Clifton district, in Tooele county, Utah, besides the typical contact metamorphic copper-gold deposits and a lead and silver-bearing deposit probably due to a small vein coming up through granite and spreading out into a flat-lying lenticular mass in the limestone, there are, in the granite area, a score of parallel fissure veins of calcite, quartz, and altered granite carrying galena said to be fairly rich in silver. In granodiorite in the Cortez district, Eureka county, Nevada, there are small veins of white quartz carrying coarse blende, galena, and pyrite and said to be chiefly silver ore. In these two cases, unless one assumes a downward circulation for the solutions, there seems no escape from the conclusion that the veins derived some lead from the eruptive rock. It is to be noted, however, that in veins of this class, the lead content is relatively low and the precious metal ratio high.²⁰ There are many lead-bearing veins and chimneys in the limestones of eastern Nevada that may have had a deep-seated origin and they almost invariably have a high silver and often high gold ratio. H. F. Bain, among others, has called attention²⁰ to the fact that the igneogenetic type of ore deposits is characterized by the presence of considerable gold and silver, while these metals are likely to be absent or unimportant in the sedigenetic type. In the practical absence of gold (the Terrible Edith excepted) and the low silver ratio where not complicated by the presence of tetrahedrite, the lead and zinc deposits of the Coeur d'Alene are more like the McGill than the Clifton and Cortez types as described above, more like the Missouri and Wisconsin ores than like the majority of lead and zinc-bearing veins of the western half of the United States. It is another count in the indictment against the magmatic hypothesis.

Elko County, Nevada

In 1905, I made a reconnaissance of the Bullion silver mining camp of Elko county, Nevada, where a small batholith of granodiorite has been intruded into the Paleozoic sediments. The contact appears to dip eastward, under the limestones, at a high angle. The mineral belt extends from the contact to about one-half mile east. I gained the impression that near the contact, deposits of iron ore and of copper sulphide ore were formed by contact metamorphic action, that at a distance from the contact these deposits pass into larger deposits in which lead-silver minerals are mixed with the copper and finally along the extreme eastern border of the belt, galena rich in silver occurs alone in thin seams in the limestone. From this I inferred that the solutions may have issued from the magma prepared to deposit iron and copper minerals and that as they rose through the limestone they derived lead from it and deposited it higher. As W. H. Emmons has since studied the district²¹ and not noted such a relation my inference may not be warranted.

At the Keystone mine, 15 miles south of Cortez, Eureka county, Nevada, sulphides of copper, lead,

²⁰'Types of Ore Deposits,' p. 102.

²¹Emmons, W. H., 'A Reconnaissance of Some Mining Camps in Elko, Lander, and Eureka Counties, Nevada,' Bull. 408, U. S. Geol. Surv., pp. 89-95, 1910.

zinc, and iron occur with contact metamorphic silicates in a point of limestone projecting into a granitic mass, and at a short distance from the contact, one of these deposits approaches the form of an ordinary vein, with a proportionate increase in the lead content. At Spruce mountain, in Elko county, Nevada, lead occurs with copper in contact deposits that appear to have been somewhat modified by secondary vein action. At the Mount Hope zinc mine, in Eureka county, Nevada, a dark zincblende, accompanied by a little galena and chalcopyrite, is mixed with contact metamorphic silicates produced by the intrusion of a rhyolitic rock into the Nevada limestone. There may be many other places in Nevada where lead and zinc sulphides are apparent primary constituents of contact metamorphic deposits, but I believe it is true that they are relatively limited in extent, have some copper sulphide and appreciable quantities of gold and silver.

Occurrence of Lead in Arizona

In Arizona, lead is usually absent from the primary mineralization of the contact metamorphic copper deposits. In a district visited by me, galena occurs with quartz or fluorite in fractures in the primary copper ore and clearly represents a later stage of mineralization. At Butte, Montana, Mr. Weed says galena "seems not to be present in the old copper veins, but to be confined to the later fault veins." Lead certainly, and zinc possibly, must be placed in a different category from copper and iron. The fact that iron, copper, gold, and silver deposits may often, with fair reason, be attributed to a magmatic source must not be held as support to the magmatic hypothesis as applied to the great lead and zinc deposits of western America. The latter must be clearly established by local field evidence. It is not sufficient to show that eruptive rocks occur in proximity to the ores and that some of the deposits have contact metamorphic characters. Thus, in the Park City district,²² while it has been shown that there is an apparent genetic connection between the ore deposits and certain dioritic intrusives, actual tracing of the lead mineral into the diorite is needed to bring conviction. In the absence of that, one is justified in placing on one side the known existence of great lead concentrations by the sedimentary process in the Mississippi Valley, and on the other the absence of any equally strong evidence of the formation anywhere of a great lead deposit, low in silver and gold, by the igneous process. What would happen if the Missouri and Wisconsin lead-zinc districts were buried under 5000 ft. of sediment and intruded by a granitic magma? There would be reconcentration of the minerals and the formation of typical lead and zinc contact deposits.

Conclusion

In conclusion, I submit that, so far as the origin of the lead and zinc deposits that are being mined in the Coeur d'Alene district is concerned, the modified sedimentary hypothesis is a rational one, that there is much field evidence tending to establish it,

and that the chief objection that can be brought against it is the fact that the supposed diffused deposits in the sediments have not been found. The last is purely negative evidence that may exist only because the proper search for these deposits has not been made. The magmatic hypothesis, on the contrary, is not supported by any field evidence that cannot be otherwise satisfactorily explained, and it is negated by a study of other mineral deposits in the Coeur d'Alene district, in the region of the great Idaho quartz-monzonite intrusion and in the western United States in general.

Osmium-Platinum: A New Alloy

By F. ZIMMERMANN

*Of the several metals of the platinum group, platinum, palladium, iridium, and rhodium have been most generally employed in the industrial arts, either alone or in combination as bivalent alloys. Of the latter, iridium-platinum is the best known, but the growing scarcity of iridium has led to the search for other combinations of the metals of this group yielding alloys possessing physical and chemical properties of equal if not greater value. The rarer metals of the platinum group are not easily obtained in great purity, and because of this fact but little success has heretofore been obtained when combining them as bivalent alloys. Furthermore, the strong affinity of osmium for oxygen has increased the difficulty of making alloys of it with other metals in definite proportions. After many experiments by the author, highly refined platinum and osmium have been successfully combined in widely varying proportions yielding alloys of commercial value. While the two metals may be combined in almost any proportion, alloys containing from 1 to 10% of osmium and 99 to 90% of platinum are chiefly used.

Great purity of the components is essential, as the presence of small percentages of other elements appears to be very detrimental to the properties of the resulting alloy. According to the chemical and physical behavior, it seems that one part of osmium in an alloy with platinum will take the place of two and one-half times its weight of iridium. The osmium-platinum alloy is very acid-resisting, and for this reason may be of great service in the electrochemical industry. Its electrical resistance is considerably higher than that of an iridium-platinum alloy of the same percentage composition. The alloy further possesses great hardness and tensile strength. Wires of the finest size are drawn with comparative ease.

The production of gypsum in 1912 was the greatest in the history of the industry, according to the U. S. Geological Survey; the amount of gypsum consumed being 2,500,757 short tons. The value of gypsum and gypsum products was \$6,563,908, an increase of \$101,873 over 1911. In 1880 only 90,000 tons of gypsum was produced; in 1900 the production was 590,000 tons.

Mining Iron Ore in Cuba

The iron ore deposits of the Mayari division of the Spanish American Iron Co. occur on an irregular plateau about 15 miles long and 4 miles wide, and at an elevation of 1700 to 2200 ft., on the north coast of Cuba, almost directly north of Santiago de Cuba. These deposits, together with those owned by the same company at Daiquiri, on the south coast, have been described in some detail by James E. Little, in the *Transactions* of the American Institute of Mining Engineers, Vol. XLII, p. 152, to which reference should be made for further details. The mining of these ores constituted an interesting problem, as they

pleted. These excavators load the ore in 50-cu. yd. standard-gage gondola cars, running on tracks laid upon the original surface, as shown in the accompanying illustration. In this way all the ore is removed down to bedrock, and the upper and lower layers are thoroughly mixed in mining. The Company now owns and operates three Lidgerwood-Crawford class B drag-line excavators, each of which digs about 1000 cu. yd. in 10 hours, the output depending on the ability of the organization to 'spot' cars for loading. The excavators have 50-ft. booms and 1½-cu. yd. buckets. They are operated by steam-power, the boilers consuming coal mined on other properties owned by the Spanish American Iron Co. Only two men are required for each machine, an

LOADING IRON ORE WITH DRAG-LINE EXCAVATOR, MAYARI, CUBA.

occur in a surface-mantle varying in thickness from a mere film to over 120 ft.; the average thickness being 18 to 20 ft. The underlying bedrock is uneven and the ore lies in pockets, and the problem in mining was to secure some type of machine that would remove all the ore down to bedrock. Another point of importance is that the top layers of ore differ in composition from the bottom levels, as nickel is present in increasing amounts with depth; the average nickel content being 0.8%. To insure an even grade of ore it is therefore desirable that the ore shall not be removed in horizontal layers, as with a steam-shovel, but in inclined slices, if possible. It was, therefore, necessary to secure some type of machine that would set on the ground-level and allow its buckets to penetrate into all the hollows of the bedrock, leaving, after the work is completed, an uneven bottom unsuited to the maintenance of tracks. The problem was solved by the use of drag-line excavators which rest on the original surface and back away from the excavation as com-

operator and a fireman. Only a few men are required for handling track, and the method shows great economy as compared with the steam-shovels ordinarily used for mining surface deposits of iron ore. The loaded cars are lowered down inclines, 6800 and 1950 ft. long respectively, two cars at a time, and sent to Felton, on Nipe bay, and then loaded into sea-going steamers for shipment to the Sparrows Point works of the Maryland Steel Company.

Although the mining industry of Servia has been at a standstill for some time, reports from that country state that Austrian and French capitalists are investigating certain properties and actively engaged in a hunt for investments of merit.

While tin continues to be the source of greatest wealth from British Malaya, the great increase in the rubber business gives promise of surpassing tin mining as a source of revenue.

The Howe Volatilization Process

The main features of this process were described in this journal of March 29, 1913, and further results on a large scale by Ben Howe, at the Gwalia Consolidated mine, Western Australia, should be of interest. This property is one of the big mines in regard to ore deposits in this state, and the lode has been traced for about 3900 ft., and over 100 ft. width averages \$9.60 per ton. Hitherto the ore, containing antimony, even in the upper levels, has resisted the best known metallurgical methods to give a reasonable extraction. The mine has produced about \$1,200,000 from above the 100-ft. level, and diamond-drilling to 500 ft. has shown \$12.48 ore. In consequence of the success achieved with the experimental furnace, a plant capable of treating 30 tons of ore per day was installed at the mine, and early in July the first clean-up from this plant had seemed to show the success of the process on a commercial basis. It was then proposed to erect

wood generator. This generator is worked by pressure, not suction. Air at about 6 to 8 in. water-gauge is blown into the generator from a small Roots blower, and the same blower also supplies hot air for mixing with the gas before burning. The arrangement is simple, and well under control of the man in charge of the furnace. Large furnaces require less attention than smaller ones, and Mr. Howe believes that in the future a furnace about 9 ft. outside diameter by 90 ft. long, treating 100 tons per day, will be a good size. Such furnaces, built of boiler plate, riveted together, would not be very expensive. Fuel consumption at present is about 16% of the ore treated, but this will be considerably reduced with a longer furnace. The regulation of temperature is an important item in the process.

Course of Gases Through the Plant

The gases are hot as they come from the furnace, and carry a good deal of dust, about 5% of the total ore. These gases pass through a dust-

DIAGRAM SHOWING THE ARRANGEMENT OF APPARATUS FOR THE HOWE PROCESS.

a 100-ton unit at once, consisting of a No. 8 Krupp ball-mill, rotary roasting furnace, condensing chambers, and gold recovery plant.

Well known metallurgists at Kalgoorlie have concluded that there are immense possibilities ahead of the process for the treatment of refractory, especially antimonial and arsenical ores, and those that will not yield a satisfactory extraction to cyanidation after roasting. In the case of the Gwalia Consolidated, the best results from roasting, sliming, and cyaniding were 75%, while the volatilization process, where the ore is roasted with salt, the recovery is 92%. Another important point is the fact that in the new process there is considerably less expenditure on equipment.

Details of the Process

The details of the process as at present running are quite simple. The ore is crushed dry, in a ball-mill, with 30-mesh screens, 5% of salt being added to the broken ore as it feeds into the mill. The mixture of crushed ore and salt is fed direct into a rotary brick-lined furnace, 27 ft. long by 5 ft. diam., making 2 r.p.m. The raw ore under these conditions roasts in the first 9 ft. of the furnace, and volatilization takes place in the next 18 ft. When the ore gets to the end of the furnace it has lost its gold and goes direct to the tailing dump.

The temperature required in the furnace is somewhat higher than that usually attained in a roasting furnace, and is obtained by gas firing from a

chamber, and then into a wooden box, 5 by 5 by 18 ft. The first 6 ft. of this box is brick lined to withstand the heat, and the whole of the top, 18 ft. long, is covered by a perforated tray which is kept full of water. This water runs through the perforations into the box as a constant shower. It is picked up again at the bottom of the box by a centrifugal pump and returned to the upper tray, thus keeping it in constant circulation. It should be mentioned that the perforated tray is divided into two parts, one for the dust portion of the box and the larger one for the gold-collecting portion. Each portion has its own separate pump. The 'dust' pump takes the water from the bottom of the box, as already mentioned, and passes it over two spitzkasten and a wooden table, like an amalgamating table, the former to remove the dust and the latter to cool the water somewhat before returning it to the top perforated tray. The 'gold' pump simply circulates the water from bottom to top continuously, but a small proportion, say 15%, passes through a gravity filter, similar to those used in clarifying cyanide solutions. From these filters the gold is removed as a black sludge, similar to that from zinc-boxes, and is melted in a similar manner.

The shower of water in the gold-collecting area falls on cocoanut-matting filters of special design, and it is through these wet filters that the fumes are made to pass. At present it is passed through one and then another of these coir filters, and so recover about 85% of the gold. During the next

few weeks a third and perhaps even a fourth filter will be tried. As a final filtration the gases pass through a chamber filled with oakum and spinifex, the latter being a tough native grass.

In the case of copper ores, more salt, even up to 10%, is required, but to compensate for this increased cost it is found that 80 to 90% of the copper content is also recovered from the ore by merely passing the gold-collecting solutions over scrap iron.

Mr. Howe states that the total cost, from the mine shaft to recovery of bullion, will not exceed \$1.80 per ton. At a recent meeting of the Company in London it is reported that the results of this process have not been up to expectations, although a number of Australian metallurgists regard the process with favor and consider it an important step toward the successful treatment of refractory ores.

The Output of Gold

By J. R. FINLAY

*Within the limitations of the question, "What is the probable limit of gold production from discovered deposits under present conditions?" it is certain that production must soon begin to decline. Many of the most important gold mines of the world are already declining. The increased production within the past few years has been due almost entirely to the great deposits of the Witwatersrand in the Transvaal. The ultimate production of this district has been pretty well estimated, and I believe amounts to some five or six thousand million dollars. Operations on this great deposit have been steadily increasing, but have now reached approximately the limit which mining engineers expected them to reach. In other words, the increased production, due to the development of deeper mines, will soon be offset by the exhaustion of the shallower mines. Outside of the Transvaal I do not know of a single important district which is in a position to increase its output substantially. In the United States practically all such districts are either decidedly on the decline or are doing well to hold their own. The production in this country has been about stationary for the past few years, but it would have already declined if the output from the established mines had not been reinforced by some new discoveries and by an increasing production of gold in the form of a by-product from mines of other metals.

Limit of Production

As to the question of how soon such limit will be reached, I am of the opinion that with no further discoveries the production of gold would immediately begin to decline. That is, it would be at its maximum now. However, gold is widely distributed, and there is a constant discovery of new deposits. How fast such new discoveries can be made is difficult to say. So far as I can make out, most discoveries are in the way of reopening old mines. New important districts have not come forward for a number of years. The latest one was the Goldfield district in Nevada, which was discovered in 1903,

and is already much on the decline. Mining engineers who have made it their business to look for gold mines throughout the world for a number of years are beginning to be somewhat discouraged, and declare that it is not a good business. While new properties are being found or old ones reopened, it is quite usual to find that they are held at exorbitant prices, which means that they must be sold to speculators and palmed off on the public for more than they are legitimately worth. Under these circumstances, it appears to me probable that even with such discoveries as are now being made, the maximum production is likely to be reached within a few years. To name a specific figure, I think it probable that this maximum will be reached before 1920.

It remains to discuss what are the probabilities of production being maintained or increased by improved processes. I think that this is precisely the point which is most promising, and at the same time most doubtful to those who expect gold production to be increased. Undoubtedly a great part of the expansion of the gold mining business in the past twenty years is due to a development of the cyanide process. Undoubtedly there is a good field left for the application of improved methods in a great many old and partly exhausted mining districts. The discovery of still better processes for the extraction of gold on new lines is, I suppose, possible, but I do not believe any such method will be found that will have much effect for another generation.

While gold has been sought in the remotest quarters of the world for many years, it must be pointed out that there are still large areas like northern Canada, South America, the interior of Africa, and the interior of Asia, where the difficulties of exploration have been so great as to impede discovery. I should say that it is not only likely but certain that important new discoveries will sooner or later be made in these regions.

Coal production of the South Wales fields in 1912 was over 50,000,000 tons, of which 36,000,000 tons was shipped by water, 23,000,000 tons leaving Cardiff. Nearly 3000 ovens in the coalfield produce about 2,000,000 tons per year. A growing number of mines producing bituminous coal convert the small coal into coke; new ovens are constantly being set up, and there is continuous replacement of old ovens by modern plants, most of which are Coppées. The bulk of the output goes into domestic consumption, and local ironworks are the chief consumers. Eleven briquette plants made 1,500,000 tons of this fuel, the briquettes weighing from 6½ to 24½ lb. each.

The Federated Malay States exported, during the first six months of 1913, 23,882 tons of tin, on which the Government collected in duty \$3,212,398 (U. S. currency), increases over the first half of 1912 of 522 tons and \$443,645. The approximate Singapore value of the exports was \$24,616,631, against \$21,742,262 last year. Wolfram exports totaled 85 tons and gold exports 5269 oz. during the period.—*Daily Consular Report*.

**The Analyst*, September 8.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Miners v. Technical Men

The Editor:

Sir—In your issue of April 26 there appeared a rather caustic article by 'A Commissary' in reply to one by 'A Miner', and as the subject under discussion is one often met with, I venture a reply.

'A Commissary' refers to the men who are largely responsible for the high standard of mining in this country as 'rough-necks'—possibly 'bone-heads' who 'hang out' at some 'joint' looking for an applicant to come along who is willing to buy a bottle of 'booze' to secure a position. With any such condition as this generally prevailing, any mine would fail to be profitable in a short time, and in my years of observation of many mines in the States and British Columbia, such conditions would not be tolerated by the miners themselves, if for no other reason than their personal safety. The general hard feeling that so frequently exists between miners and college men is many times the fault of the latter. In this, I do not include the mature collegiate who has gained practical experience as well as the faculty of recognizing the other man's knowledge, but the young college graduate.

The miner, as a class, will receive most kindly any information or suggestion from any technical man who is mature enough to convince him that he knows the business, but it is really amusing at times to hear the schemes and proposals put forth by the lad who, perhaps, has secured his college degree, and with it more or less technical knowledge (probably from the best authority, but badly scrambled), as he tried to improve on the work of an old experienced head. The miners can scarcely be blamed for being a bit skeptical of a new man, as there are such a number of 'jokes' at large who term themselves 'experts.' There are, of course, exceptions, but the general run of Western miners are intelligent, efficient, sober, and industrious individuals, from whom many of the best educated college men can gain much first-hand information; but the miners' knowledge is usually underestimated, for as a class they are not inclined toward letters, and the air of superiority carried by the immature graduate does not invite the confidence of the miners nor the interchange of much that might be mutually helpful.

Miners do kick about board. Most of the complaint, however, is not with the quality of meals supplied, but with the lack of cleanliness and tastefulness in the preparation and serving of the food, and this kick is frequently justifiable. Proper housing and good food well served will do much to make hard-working men content and self-respecting. I believe most miners are doing their best for the company's interest, and certainly the college man can do no more. The difference lies only in the fields of usefulness and opportunity, and the great-

est results will be seen just in the proportion that each is willing to acknowledge the wisdom and experience of the other. The college man who learns at the start of his career that he needs to supplement his technical knowledge with years of practical experience and close observation will in the end win man's favor and attain success. There are faults on both sides, but the miner has by far the harder lot, and his physical labors rob him of much of the time and strength that the college man can give to broadening his intellect by study and reading, which should thus enable him to widen his outlook and see the good in everything.

E. LE ROY.

Motherlode, British Columbia, June 26.

'Ore'

The Editor:

Sir—In your issue of September 13, T. A. Rickard, with his usual graciousness, confesses to redundancy, but then we know that Mr. Rickard is not often redundant, and there must be a reason if he becomes so, in order to avoid being misunderstood by the professional men who are his readers, and who, it may be taken as a hypothesis, are familiar with the language of their profession. The other words in our mining vocabulary need no redundant qualifying to make the individual words intelligible. By applying the standard of profit to the word ore, we restrict its meaning in an endeavor to make its use more exact. But why arbitrarily select one word from our vocabulary and treat it in this way, and say that the vast majority of the profession use it incorrectly because they do not agree with the reformers? We use many words in a manner similar to the generally accepted use of the word 'ore,' and the whole class needs qualification to convey an idea of exactness where such is intended to be conveyed.

Take the range of minerals that go to make up the more common ores—such as chalcopyrite, hematite, blende. If we speak of a body of chalcopyrite, does it give any idea of the percentage of copper? Does hematite necessarily imply a fixed percentage of iron, or zincblende a fixed percentage of zinc? The answer, of course, is in the negative, but if the reformers are right about 'ore,' then all these words should be treated in the same way. Then there is the word slag, which in many respects is kin to ore. The word alone conveys no idea of quality or quantity. If the metallurgist gets too much of my copper in his slag, because perhaps he has miscalculated his charge, then my good ore becomes what—waste, or unprofitable ore? I know Mr. Rickard will reply that this fluke on the metallurgist's part does not apply to the particular case.

Now if one considers Mr. Rickard's definition carefully—"ore is metal-bearing rock which at a given time and place can be exploited at a profit"—he is struck by its great flexibility. It can be stretched over nearly any objection that can be raised. That "time and place" business almost ruins all one's arguments—almost! The trouble comes in its application, because as soon as it is stretched to cover cases like adjoining mines working the same ore,

the one at a profit, the other at a loss, it loses its significance and we flounder back in the same bog as before, and have to use 'profitable' and 'unprofitable' to make ourselves understood.

Mr. Rickard has dared me to give a definition of ore—well, to be frank, I didn't expect him to pull a gun on me that way, and my hands go straight over my head. I did that once, Mr. Editor, and I really wish I hadn't, because I am no hand at making definitions. In future I intend to leave that to those with a better knowledge of the English language.

I do not wish to take up too much of your valuable space, as I have expressed my views fully in my book, 'Mine Sampling and Valuing,' which you now have in the press. I must say, however, that I remain unconvinced—and feel very much like one of the past presidents of the Institution of Mining and Metallurgy, a leader in the profession, who, at a round table conference on this subject, when pressed for a definition, replied to another ditto: "Ore is ore—and if you know the mine you know what I mean."

C. L. HERZIG.

Tulsa, Oklahoma, September 23.

The Institute and the Society

The Editor:

Sir—The editorial on this topic in your issue of September 6, which has just come, has interested me greatly. Concerning so large a matter as this there is room for many honest differences of opinion, and, knowing the traditional policy of your journal, I am sure you will be willing to accord space for an argument somewhat different from your own. Being a member of both societies, and resident near their headquarters, I have been able to keep somewhat closely in touch with the progress of these negotiations, so that the following personal opinion is based, I believe, upon the essential facts.

The progress of affairs has seemed to me remarkably like the investigation of a new metallurgical process by the staff of a mining company; a preliminary period in which the proposals seem very attractive, an interim of careful investigation and study, and a final careful weighing of the evidence resulting in a decision not to adopt the scheme in its final form. You say "Those directors who felt they could not vote favorably should have made their influence felt earlier." It is not clear how the directors could have known what their vote would be until the evidence was all in, and it is quite conceivable to me that individuals who at first favored the amalgamation might, after months of thought and discussion, come to take the opposite view. I have been told that the vote of the board of directors of the Institute, many of whom are prominent members of the Society, was almost unanimous in deciding not to affiliate with the Society under the terms proposed. You will remember that the original terms of affiliation as drawn up by the council of the Society met with much opposition among its members, and it was only after much discussion and a referendum vote that agreement was reached. It is unquestionable that there must

still exist in the Society a minority unfavorable to affiliation. Meanwhile, as I understand it, there had been growing up in the Institute a belief that the creation of a group of "preferred stockholders" within the Institute was likely to lead to serious friction. I have frequently heard cited the experience of the American Institute of Electrical Engineers, which, by a vote of its members, created a class of fellows. Later certain members brought suit in the civil courts, alleging that the creation of such a group was an infringement on the vested rights of the other members. It is true that the court held that, since this action had been taken by a vote of the entire membership, no grounds for such a suit existed, but the incident is illustrative of the amount of feeling such an action is able to evoke in a simple and uncomplicated situation such as existed in the Institute of Electrical Engineers. The Institute of Mining Engineers is just recovering from the strain of reorganization, and there was evidently ground for a belief that the effect of a similar action would, in their case, be at least not less serious. From what I have heard, I am strongly of the opinion that this consideration, more than any other, influenced the decision of this matter.

There are many, who, like yourself, believe it would be better for the profession to have one national society rather than two, but that does not avoid the practical problem as to whether it is feasible to recast the Institute, with a history of forty years of membership 'on the level', into a mold of classes of membership. Many of its members, myself included, feel that it is not. Everyone is familiar with the fact that the metric system was adopted years ago as the legal system of weights and measures in this country, and yet hardly any progress has been made in its introduction into general use. Humanity *en masse* is one of the most difficult substances on which to make radical alterations, and the task may well cause much hesitation.

Finally, it is well to consider whether the two organizations can not render nearly or quite as high a degree of professional service by continuing their separate existence. To my mind, the degree of success which the Society has already attained has largely grown out of the fact that its membership is small and select; with the emphasis on the small. The number of those engaged in the work of the mining profession who are really interested in broad fundamental questions of legislation, political economy, and social progress is few indeed, and they represent almost as great a variety of opinion as their own number. The activities of such a group carried on within a body which is somewhat inert is likely to produce more of ferment than of useful reaction. Gathered together in a small body of men of similar methods of thought, their activities would be highly important and useful. In politics it is a recognized principle of government that it is best to have two legislative bodies: in technology it may well prove that it is best to have two national societies, one inclusive, the other select. The functions of the Institute are primarily technical, but to round out its work it must touch

on the broader phases of public and social questions. The Society is primarily devoted to the broader phases of mining and metallurgy, and has little need to venture into the field of technology, since nearly all its members are, and doubtless will continue to be, members of the larger organization. Each can operate best in its own especial field, just as a carpenter finds use for both a broad-axe and a draw-shave.

I can heartily second your recommendation that the outcome of these negotiations be taken with good humor. Why should it be otherwise? Every year differing varieties of political opinion are urged, and but one view prevails at the polls, whereupon everyone proceeds to make the best of it with entire good humor. To me it appears that the Society has accomplished a distinct service in bringing about the reorganization of the Institute, and that it may now proceed to direct its energies toward other useful objects, of which there is no lack.

A MEMBER OF BOTH.

New York, September 12.

Transportation Problems in Bolivia

The Editor:

Sir—In reference to the article by G. W. Wepfer, 'Railroads and Transportation Problems in Bolivia,' in your issue of July 19, the following may be of interest:

Generally speaking, drilling is done by hand, but jackhammer drills, also heavier types, are being rapidly adopted in the important tin mines and in Corocoro (where electric auger drills were not successful). The Peruvian oilfields, in the vicinity of Lake Titicaca, have been abandoned for some years; arrangements are said to have been made to bring up tank cars from Antofagasta, wherever the railroad can reach the consumers. At present both residuum and distillate are brought up in oil-cans. The tax on mineral land varies; for coal, oil, and gold-placer the pertenencia is 200 metres square, and the yearly tax is 2 bolivianos (80c. U. S. cy.); vein mines are 100 metres square, and the yearly tax is 4 bolivianos (\$1.60 U. S. currency).

There are no standard-gage railroad lines in Bolivia. With the exception of the Antofagasta-Bolivia line, between Oruro (Bolivia) and Antofagasta (Chile), and the Huanchaca line between Uyuni and Pulocayo, both 30-inch, the gage of existing lines is a metre. The sketch map shows a line in operation between Carana (probably intended to be Caqueña) and Corocoro, which has been placed on the Antofagasta-Bolivia line (from which point it lies many miles to the northwest); as a matter of fact, Corocoro is on a branch line of the Arica-La Paz railroad, which latter has been open for traffic since last fall. The line between Rio Mulatos and Potosi has been in operation since late last year.

The hotel accommodations in La Paz are decidedly poor and leave much to be desired; they do not compare favorably with those in other large towns on the West Coast.

LESTER W. STRAUSS,

Lima, Peru, August 19.

Common Sense of the Fume Question

The Editor:

Sir—Of all the pro-smelter drivel that it has been my misfortune to read, the contribution of Herbert Lang, in your issue of August 30 is the least endurable.

Entrenched in assumed scientific datum and technical phrases, the object of Mr. Lang is unmistakably to misinform and mislead the ignorant or the casual reader. It is apparent to any other that he is either a flunky or that he is hopelessly unbalanced. I regret that your journal, either carelessly or injudiciously lends itself to the indorsement of literature of this character, which in effect profits nobody, and which can but prove pernicious and disastrous to all concerned in it, or in the commonwealth. The support lent by journalism to corporations engaged in rapacious exploitation of the common resources of the country presents one of the darkest phases of human endeavor. When the effects of what appears to be journalistic conspiracy between the press and such predatory factions as the Pacific railroads and Western smelting associations, eventually converge and collapse, all those working to that climax will reap as they have sown—they or their descendants—while many blameless fellow-beings will be also involved.

Ignoring Mr. Lang's struggles with his scientific analyses of furnace fume, I will only ask you to test the more material parts of his text, in which he permits his animus and his opinions to show in accusing, arraigning, judging, and in condemnation. He is general and broad in his wholesale and summary edictum. Both persons and property interests are considered, but Mr. Lang, like other ardent exploiters of material values, places the latter commodity in the precedence. He evidently reasons that both should be reduced to matte and spelter. In effect, Mr. Lang's mania seems to centre and swirl about the choice epithet 'smoke farmers,' a unique and characteristic product of pro-smelterism, as it is employed and somewhat overworked by lieutenants of the industry. 'Smoke farming' is a choice and peculiar epithet, and it is almost a pity to find it merely a dishonest term in use by liars to stigmatize pioneer settlers and good citizens who are trying to protect their homes, property, and lives against the brutality of organized exploitation and vandalism.

A journal with the resources and advantages of yours cannot, or, at least, need not be ignorant of facts and conditions within its immediate field; and your more intelligent and solicitous readers will judge your work according to its merit, just as any other work is judged in its ultimate development and display. Do you, Mr. Editor, believe that there is such a person as a 'smoke farmer' who blackmails smelting corporations? Do you believe that any smelting corporation or industry in the West submits to extortion, as alleged by Mr. Lang? If you do, and hold opinion with these abused and mulcted corporate industries, with your combined resources and ability, why have you not, or why can you not make an awful example of one of them? You certainly cannot plead that the law is deaf to

corporation prayers in this country, or this state. You certainly have as much shelter and protection by courts and juries as is enjoyed by the miserable desert rancher who assails, according to Hr. Lang, these interests by "tying a sick horse in the 'path' of the smelter smoke, and makes the smelter pay the price of two good ones for killing one." Mr. Lang is doubtless deaf to the heretic blast, blown in the West, that what is not sense must be nonsense; or that it is drivel, which has usually been paid for.

Mr. Editor, do you not know that all efforts to suppress what is widely known to be a destructive nuisance of the worst character have been repeatedly defeated in California? Do you not know that the federal government is defied by the smelter interests? That state government is helpless or inert? That county grand juries and local organizations are the laughing stock and joke with these corporations? The grand jury of Shasta county, a few months ago—than which we have had no more intelligent or honest men of authority—condemned the smelter nuisance as a public nuisance. The district attorney of the county, with notable alacrity, published the statement that they were helpless, or that he was. That seemed to end the matter.

The defense of the smelting people is wonderfully simple, so much so that it looks like a slur upon American intelligence and common sense. Admitting that their smoke can be made harmless by various processes, they say the by-products obtained will not pay the expense. In other words, their reply to the unfortunate public is, that they prefer still to employ agents, attorneys, and flunkies to cover up, befog, and prostitute, while they continue, serenely, to destroy, devastate, and kill.

Mr. Editor, you are requested to print this statement of facts over my signature, assuming no responsibility yourself. You have my permission to comment upon it as acridly as your conscience will permit. In your interpretation of the signs of the times, you must perceive cardinal writing, that what is not right and rational is reactionary and disastrous, and that the process has a rapid tendency westward.

CHARLES L. PAIGE.

Shasta, California, September 1.

The Editor:

Sir—It is quite apropos that Mr. Paige has delivered himself of his very characteristic critique of my article on this subject, since it exhibits to your readers more plainly than I could have done by any amount of writing the peculiar and extravagant animus prevailing among a certain class of our small landed proprietors and their hangers-on. It is easy to see how difficult it must be to settle the local questions of fume damage on any possible basis of give and take where such sentiments prevail. Such people have no conception of such a thing as an honest difference of opinion, and the utter wiping out of a great and flourishing industry affects their opinions not a particle. The same sentiments are heard in courtrooms during the trial of smoke suits, which, so far as I have

observed, originate in this manner:

Some pestilent agitator, usually a pettifogging lawyer of small calibre from the county seat, goes among the farmers and organizes a clique to fight smelter smoke. He painfully coaxes a few dollars from their reluctant purses for the preliminary expenses, and arranges to receive his own reward in the form of contingent fees; that is to say, he is to get a proportion, usually one-half, of whatever he can screw out of the smelting company. As it invariably costs the latter a great deal more to defend the case than the plaintiffs to bring it, the greater number of such affairs are settled out of court, by the payment, perhaps of 10 per cent of the amount of damages claimed. It will be understood that the expenses of defending these suits to the company are extremely heavy, notwithstanding which they have thus far led to no conclusive results.

In fact, it seems to me that the money thus spent in feeing lawyers and for other purposes has been entirely wasted. I question if a single dollar of it has been wisely spent. It appeared to me at the first that the only wise and proper expenditures were those incurred in the actual purchase of the land. I believe that if the Mountain Copper Co., which was the first in the field in Shasta county, and on whose shoulders fell the first burdens, would have done better to have laid out the \$300,000 since devoted by it to legal and other costs in connection with these suits, in buying the surrounding lands. I may say incidentally, that I gave them this advice during my connection with them some 17 years ago, at a time when that amount of money would have secured possibly the whole area now claimed by orators of Mr. Paige's kind to be a scene of devastation.

As a matter of fact, it happens that the land in question is of small value; certainly the amount spent in litigating thus far would exceed its worth, then and now, many times over; but it would have been a peaceful solution of an unpleasant difficulty. Furthermore, the re-sale of the land with a smoke clause inserted in the deed might have reimbursed the companies for the outlay. It is regrettable that the active fight waged in Shasta county has drawn public attention to the fume question, and has incidentally opened a promising avenue for the exercise of pettifogging talents and chicanery beyond the ordinary. The contest has become nation-wide, and its results are prejudicial not only to a suffering industry, but to the future development of the country.

HERBERT LANG.

Oakland, September 30.

[Mr. Paige's communication presents the other side, which is entitled to, and shall always have, a hearing in the *Mining and Scientific Press*. Where difference of opinion is so wide as that between our correspondent and ourselves, there is no common ground for argument. We respectfully differ from him as to premises and conclusion, but we are glad to print his letter as an expression of a feeling that must be taken into account in attempting to solve the problems of smelter fume.—EDITOR.]

Special Correspondence

NEW YORK

NORTH STAR SHARES.—ANACONDA AND BUTTE-BALLAKLAVA.—
WASHOE SMELTER SHUT-DOWN.—ALASKA GOLD MINES CO.
—DIVIDENDS.—INTEREST OF NATIONAL RAILWAYS OF MEX-
ICO PAID.

The collapse of North Star has been the market topic of the week, and the good sense of those who refused to have anything to do with it from the beginning has been amply vindicated. The blame is being placed upon James Heney, the mine foreman, who is alleged to have deceived the superintendent, while supplying private information to Bush street, San Francisco, brokers. It is said that he was convicted several years ago of robbing the Carson mint. That being the case, he was among worthy associates. It is just such affairs as this which serve to totally discredit share dealings on the 'Curb,' as the open-air market in Broad street, in front of the New York Stock Exchange, is called.

Rumors that the litigation between the Anaconda and Butte-Ballaklava was about to be settled were without foundation in fact. What is of more importance is the impending shut-down of the smelter at Anaconda for a week, in order to allow repairs to be made to the flue system. This will cut off about 750,000 lb. of copper per day from smelter output, and at the rate things are going, the copper trade will soon be operating on a deficit instead of surplus stocks. Some people are rude enough to suggest that possibly the metal market is being manipulated in order to produce activity in the price of shares.

Joseph W. Harriman, president of the Harriman National Bank, has been made a director of the Greene Cananea Copper Co., and will be a strong addition to its board. When E. H. Harriman died, the inventory of his estate showed that his holdings of mining shares were mostly of a peculiar variety. It is interesting to notice that this seems to be almost the general rule; and the more important a man is in the industrial and banking world, the more dubious his mining investments are. Mr. Harriman's affiliation with the Greene Cananea shows that he is disposed to be an exception to this rule.

Alaska Gold Mines shares sold in Boston around \$24 on September 26, and it is to be regretted that *Mines and Methods* has suspended publication, for what it would have to say ought to be as interesting reading as some of Thomas W. Lawson's outpourings were before they, through familiarity, sunk from being exciting to merely wearisome. It is reported, by the way, that its publication is soon to be resumed in New York, with Sidney Norman as editor. That being the case, we may expect some interesting reading about the Guggenheims. Returning to Alaska Gold Mines, the published prophecies of earnings at the rate of \$7 or \$8 per share per year are based upon estimates of total costs for mining and milling at 60c. per ton. On this point the average engineer is 'decidedly from Missouri.'

The United States S. R. & M. Co. has declared its regular quarterly dividend of 1½% on the common and 1¾% on the preferred, payable October 15. The Anaconda has also declared its regular quarterly dividend of 1½%, although it is earning at a much higher rate on the present price of copper. Sound policy, of course, requires that dividends be held as steady as possible, consequently when earnings are high they are accumulated to maintain dividends when the price of copper goes down.

The interest on the \$51,000,000 of 4% gold bonds of the National Railways of Mexico was paid on October 1 from the loan funds which were arranged for early in the summer. The tramway system in Mexico City has been prosperous despite the revolution, and reports good earnings for the past year. The Wettlaufer-Lorrain is the reverse of prosperous, and has recently declared a dividend of 5c. per share, to be paid out of its capital. What is to be done with the remainder will be decided at the annual meeting next January. The directors of the Ohio Copper Co.

are still considering the problem of how to put that much-vexed property on its feet again. There is general opposition to continuing to pay 15c. per ton for transport through the Mascotte tunnel, and it has been proposed to reduce it to 10c. per ton. As the tunnel company has little revenue from any other source, a vigorous protest from its bondholders in France may be expected in case this is done.

BOSTON

NORTH BUTTE EXPANSION.—HALL DESULPHURIZING PROCESS.
—BOSTON & MONTANA DEVELOPMENT CO.—THE LAKE
STRIKE.

North Butte shares have recently been more active, resuming their speculative leadership among the coppers here, advancing to around \$30, within about five points of the high price of the year and 10 points of the high price of last year. The activity and advance are based on reports of large acquisitions of new properties and of new orebodies being discovered on the 2200, 2400, and 2600-ft. levels. The Company will issue stock to pay for new territory in the northern and eastern part of Butte, 1000 to 1200 acres, which was optioned by Mr. Thornton for

ANACONDA HILL, BUTTE.

the North Butte company at a cost of about \$1000 per acre. North Butte has 190,000 shares of treasury stock unissued out of 600,000 shares authorized, the unissued stock having a present market value of approximately \$5,500,000. All of this stock is available for the purchase of additional mining property. The Company's original estate is about 160 acres, so the expansion will make the property about six times as large in amount of territory held, and the largest owner of mineral ground in Butte. The statement that the Guggenheims have joined Thomas F. Cole in North Butte's future plans has been denied in Boston, so vigorously as to suggest the idea that too much protesting is being done. The Guggenheims have been credited with the desire of extending the foothold they have gained in Butte, through their interest in Butte & Superior, and it is natural to suppose that North Butte would offer them a fair opportunity to do so. If North Butte takes over this new territory, including Butte & Amazon, Ida-Montana, Rainbow Development, and possibly Butte & London, it will be in a fair way to have a much larger share capitalization. If the troubles of the Tuolumne company continue, it is possible that little property would be absorbed by North Butte, and in case of a big merger and the stock market campaign which would result, Butte Main Range might be considered as within the horizon of probable consolidation. It is evident that there are big things brewing on the northern side of Anaconda hill, and the public will hear more about these as they develop.

It was reported in Boston a few days ago that an injunction was about to be served on the Hall desulphurizing process at the First National smelter. This process, or some variation of it, has been used in some of the pyrite smelters in France. The idea became current here that perhaps some of the foreign interests in the patent

were moving to make trouble. Your correspondent sent a representative to see Mr. McSweeney, of the Lawson office here, and also Mr. Clapp, Lawson's confidential broker. Mr. McSweeney said he had not heard of the reported injunction at all. Mr. Clapp admitted hearing of it, but said that it was not a matter of any consequence to the First National people. He believed it was simply a trick to rig the market.

Mexican Metals figures in Curb activity these days, but has never recovered in price since the break below 50c. per share. Officials of the Boston & Montana Development Co., which is undertaking the building of a road southwest of Butte into Deer Lodge and Beaverhead counties, announce that the first link will be from Divide, on the Oregon Short Line, to the French Gulch district, where, it is claimed, the Company's mines are in such a stage of development and equipment that shipments of ore can be started at any time to the custom plants at Butte and Anaconda. The next link of the road will be up the Wise river to Elkhorn, in Beaverhead county, where the president of the Company, W. R. Allen, former lieutenant-governor, will begin the driving of a 3000-ft. main working adit at the base of the mountain, to develop and handle the ores of the district. The engineering corps in the field recently assisted in saving the Big Hole power-plant, three miles west of Divide, on the route of the new road, from being destroyed by a forest fire. The timber in that district is extensive, supplying a great deal of material which goes underground at Butte.

The Lake strike has enforced the curtailment of disbursements among the dividend-paying companies. Those which curtailed dividends include Copper Range Ahmeek, Calumet & Hecla, Osceola, Mohawk, and Quincy, and a postponement of action as to the semi-annual declaration by Wolverine. The main support of the Western Federation in its fight to gain a foothold in the Lake district comes from Butte organized labor, and citizens of Butte are joining in their sympathy. A sympathetic mass-meeting was held at Butte recently, and a petition and memorial were sent to the United States Senate making an attack on what they called 'the Boston Coppers.'

TORONTO, CANADA

THE GIFFORD PROPERTY.—RESULTS AT THE TRETHEWEY.—NIPISSING FINANCES.—LUMSDEN DEVELOPMENTS.—HOLLINGER RESERVE, EAST DOME, SWASTIKA, AND WISEMAN PROPERTIES.

The option held by a syndicate of Montreal capitalists on the Gifford property adjoining the Beaver, has been allowed to lapse, nothing of value having been opened in several hundred feet of development work on the 200-ft. level. The net profits of the Trethewey have averaged about \$8000 per month during the current year, and have lately shown a considerable increase. During August the mill treated 3068 tons of ore of an average grade of 22.4 oz. per ton, producing 55,102 oz. of silver in the concentrate, valued at \$32,510, the net profit being about \$13,300. The financial statement of the Nipissing as at September 20 showed: cash in bank, \$1,192,297; ore and bullion in transit, \$24,245; ore on hand and bullion ready for shipment, \$182,980; a total of \$1,399,522. The Lumsden company has found good ore at the 250-ft. level in the diabase underlying the Keewatin formation, the vein being 5 in. wide, assaying about 1000 oz. per ton. The continuance of operations at the Wettlaufer, in the South Lorrain area, depends on the result of horizontal diamond-drilling, which will be carried on until December in the hope of finding new ore-shoots. Stanley N. Graham, manager of the Peterson Lake, has resigned his position, having been appointed professor of mining engineering in the Technical College, Halifax. John Hare, a well known English financier, is on his way to Cobalt to examine a number of mining properties and report to prospective British investors. At the Seneca-Superior, the Worth vein has been cut on the 325-ft. level, where it continues as strong as on the upper levels.

The Hollinger, at Porcupine, is enlarging its mill by the

addition of 20 stamps, making 60 in all, bringing the crushing capacity up to 650 tons per day. It is hoped to have the new unit in operation by the end of the year. Foundations are being laid for the permanent central power-plant, which will serve the Hollinger and the affiliated plants of the Dixon, Gillies, and Miller-Middleton. The deal by which the Lewisohns are to purchase the Hollinger Reserve, which has been under negotiation for some time, is progressing toward a conclusion, the payment of a first instalment of \$20,000 on the purchase money having been made. The old Preston-East Dome properties, abandoned after the expenditure of a large amount of money, are making a good showing under the management of Harry Offer and associates. An open-cut 30 ft.

COBALT LAKE MINE, COBALT.

long by 20 ft. in depth has yielded 20½ tons of ore, returning \$175 per ton. A shaft is being sunk, and development at depth will be undertaken. The Swastika has been closed until arrangements can be made for financing. High-grade ore was found between the 100 and 200-ft. levels, which led to the installation of a costly surface equipment and operations at a further depth on a large scale, which failed to meet current expenses. Harry Cecil, representing English interests, has taken an option on the two Wiseman claims adjoining the Tough-Oakes property in the Kirkland Lake district, which will be operated by a new company under the name of the Telluride Gold Mines, Ltd., capitalized at \$1,500,000.

BUTTE, MONTANA

THE WASHOE SMELTER.—ALEX SCOTT, BUTTE & LONDON, PILOT BUTTE, BUTTE-BALLAKLAVA, BULLWHACKER, BARNES-KING, RAVEN, BUTTE & ELY, AND BUTTE & SUPERIOR OPERATIONS.

An unusual occurrence is about to happen at Anaconda. The fires at the big smelter will be drawn for about ten days for the purpose of cleaning out and repairing the flues leading to the stack. The cost of such a shut-down will necessarily be large, as all the furnaces will freeze. It seems unavoidable, however, that occasionally the flues must be cleaned. Incidentally, the copper production for October will be reduced considerably, but this will probably be made up before the first of the year. The concentrator and mines will continue as usual, the concentrate being stored for later use in the smelter.

The Butte-Alex Scott Copper Co. has opened a good ore-body on the 1900-ft. level of the Alex Scott mine. The Company is shipping about 150 tons per day to the East Butte smelter. The shaft is being continued to the 2200-ft. level.

As soon as the electric machinery can be installed, the work of unwatering the shaft of the Butte & London Copper Development Co. will be undertaken by the T. F. Cole interests. The shaft is to be deepened to the 2000-ft. level. The Pilot Butte Mining Co. has begun shipping copper ore to the smelters at the rate of 50 tons per day. It is planned to arrange for increasing the output in the near future. The flurry in the stock of Butte-Ballaklava Copper Co. based on the rumor that Anaconda was negotiating for the purchase of the property, was apparently a stock-manipulating scheme. C. F. Kelley, vice-president of the Anaconda Copper Mining Co., denies any knowledge

of negotiations with Ballaklava, so that there is probably nothing to it.

The long-standing lease on the Bullwhacker mine has finally expired, and the company will operate the property itself from now on. The leaching plant is nearly ready for operation, and in a short time the company expects to be shipping commercial cathodes.

The Barnes-King Development Co., which has many Butte stockholders, is apparently satisfied with development at its Marysville property, for final payments on the purchase price have just been made. The Company is now practically in complete ownership of two promising properties, the North Moccasin at Kendall and the Piegian-Gloster at Marysville. The North Moccasin has been paid for out of operating profits, and the Piegian-Gloster was purchased from capital in the treasury. Under the existing conservative management the outlook for Barnes-King is much better than at any time in the history of the Company. It will not be the policy of the management to declare any dividends, however, until the present holdings are properly equipped and on a sound producing basis. The Raven Copper Co. has apparently given up hope of making a mine at depth. The pumps have been drawn and the lower levels will be allowed to fill. The Raven property is near the border line between what are referred to as the copper and silver zones, but the veins seem to be on the wrong side of the border for copper. The minority interests in the Butte & Ely Copper Co. who tried to throw the Company into the hands of a receiver, have failed in their efforts, their prayer having been denied in the District Court here on September 16.

The August zinc production of the Butte & Superior certainly gives encouragement to the thought that Butte may soon be producing as much zinc as copper. And this promising state of affairs at the Butte & Superior is all the more satisfactory as it appears to be a natural outcome of what seemed like the wildest confusion at the mill a year ago. Machines were no sooner put in than out they would come again, and men and bosses were so thick that everything seemed to be in chaos. Apparently experiments were necessary, however, and have finally resulted in the evolution of a satisfactory milling practice in which 50% zinc concentrate is made with a 90% saving. This saving includes, of course, the flotation returns. The successful operation of the Butte & Superior mine and mill is undoubtedly the most important mining event in Butte since Marcus Daly opened the Anaconda mine.

JOPLIN, MISSOURI

NUMBER OF MINES PRODUCING IN MISSOURI-KANSAS-OKLAHOMA ZINC AND LEAD DISTRICT.—BIG MILL OUTPUT OF MIAMI, OKLAHOMA, CAMP.—ZINC AND LEAD NOTES.

More than 300 separate mines are contributing to the weekly production of zinc and lead ores from the Missouri-Kansas-Oklahoma district, which is now averaging about 5200 tons of zinc sulphide concentrate, 600 tons of calamine, and 1000 tons of lead ore per week. A large number of small new mines have entered the producing lists within the past few months. The bulk of the output, especially that of zinc sulphide, comes from mines that are equipped with mills, although there are a large number of mines from which the ore is treated by hand jigs. A larger percentage of the calamine production comes from hand-jig plants, as this ore, as a rule, is found in rich, shallow pockets. The mineral is often in large, free 'chunks,' ready for the smelter after the residual clays have been washed off. Considerable lead ore is also found in shallow, rich deposits, and is easily cleaned by hand jigs or is hand sorted. With the opening of more extensive orebodies, the tendency is to construct milling plants of greater capacity than formerly.

One of the twenty-odd camps of the district is distinctive in that it produces almost exclusively from big milling properties. This is Miami, Oklahoma, a region that in the four or five years of its rapid development has been almost entirely free from small mining enterprises. There are no hand jigs at Miami, no small crushing plants, noth-

ing but large concentrating mills. In addition to the big mills now reducing ore in this district, several new plants have been completed recently and others are to be built in the near future. The district is being developed rapidly for a distance of several miles north of the present producing region, operations having been extended to a depth of 275 ft. in places. There is still a great deal of mining to be done in the upper ore-shoots at a depth of 90 to 110 ft. The shallow ore, however, is invariably heavy in iron and is thus penalized by the buyers. The deeper ore is of much better grade, the zinc concentrate containing as high as 61% metal, while the galena goes 80% in metallic lead. In most camps of the district, ore is sold from week to week to the smelters making the highest bids. Virtually all of the Miami output is sold

MAP SHOWING MISSOURI-KANSAS-OKLAHOMA DISTRICTS.

to the American Zinc, Lead & Smelting Co. on a contract, based on the price of spelter at East St. Louis, Illinois.

Coal has been opened at a depth of 45 ft. at the Shamrock mine, north of Alba, Missouri. The operators will sink to the zinc and lead formation, encountered in drilling, but are driving on their coal seam and using the fuel with which to carry on operations. A heavy tonnage of the coal is sold to nearby mining companies. The vein is 6 ft. in height and is 35 ft. wide, and the quality is good. No coal-mining of importance has been undertaken in this region heretofore.

Sludge tables and other improvements have been added to the big concentrating plant of the Bertha A. Mining Co., operated by Charles T. Orr and associates at Webb City, Missouri. After an idleness of several months, this mill is again in operation. Another large mill, of the sheet-ground district, to resume operations recently, is that of the Charleston Mining Co., one of several properties operated by the C. M. Sheldon Mining Co. The mill recovery is about 2.5% zinc sulphide and 0.5% galena.

The driving of shafts from the bottom upward is becoming of common practice throughout the district. Following the example of the Nowata Mining Co., of Duenweg, Missouri, the Hartford Mining Co., of Galena, Kansas, has driven a large shaft from the bottom upward. A drill-hole, through which a cable is passed, connects with a platform at the bottom on which the shaft men work. The shaft was driven 200 ft. in this manner, and was sunk an additional 65 ft. beneath the old drifts in the ordinary manner. Work is to be extended to a depth of 300 feet.

Prices for zinc ores at the beginning of October have weakened over those of September. The range in price for zinc sulphide ores carrying 60% metallic zinc is \$44 to \$46, with choicer lots bringing as high as \$49 per ton. Metal is quoted at 5.55c. per pound. For the corresponding week of 1912, ore brought \$58 to \$62, basis, with choicer grades selling up to \$65. Metal was quoted at 7.45c. Calamine sells for \$21 to \$23 per ton, basis of 40% metallic zinc, while choicer lots bring as high as \$27. For the corresponding period of 1912, calamine brought \$29 to \$33, with a top of \$37 for the best grades. Lead ore continues firm at \$58 per ton, 80% metallic lead, compared with \$68 for the corresponding week of 1912. Metal is dull at 4.50c., compared with 5c. for the corresponding week of 1912.

General Mining News

ALASKA

FAIRBANKS

An 18-in. vein, worth \$30 per ton, has been opened on the 100-ft. level of the Newsboy mine. Good ore is now being extracted from the 100, 150, and 200-ft. levels, and prospecting is being done at 300 ft. The mill has been working 16 hours per day since August 17. An 18-in. vein, containing rich gold ore, has been uncovered at the Tolovana claim, on Willow creek. A shaft has been sunk 22 ft. in good ore. A trial lot will be crushed by the two Nissen stamps.

ARIZONA

COCHISE COUNTY

During the first eight months of the current year the Copper Queen mines have produced 100,799,648 lb. of copper.

GILA COUNTY

Reports on copper deposits near Superior, by F. L. Ransome, and the copper deposits of the White Mesa district by J. M. Hill, have just been issued by the U. S. Geological Survey in one pamphlet as advance chapter D of Bulletin 540. The Silver King is the most noted mine in the vicinity of Superior. It was opened in 1875 and for many years produced high-grade silver ore from a deposit of the form commonly called by miners a 'chimney.' The mine is now idle. The production of the Silver King is variously reported as between \$10,000,000 and \$15,000,000. The lower figure is probably too high, but the Silver King Mining Co. is known to have paid dividends up to July 1887, amounting to \$1,950,000. The Queen or Silver Queen mine, about three-fourths of a mile north of Superior, although opened as early as the Silver King and credited with some production about 1880, has only recently become important through the activity of the Magma Copper Company.

The case of James A. Fleming v. the Black Warrior Copper Co., amalgamated, to have the transfer of that Company's holdings to the Warrior Copper Co. set aside, must be tried in the Superior Court of Gila county. Such is the decision of the Supreme Court at Phoenix.

GREENLEE COUNTY

One of the new furnaces at the Arizona Copper Co.'s new smelter 'froze' during the week ended September 20. It will be several weeks before it is in operation.

A decision involving about \$50,000 has been handed down by the Supreme Court at Phoenix in the case of the Arizona Copper Co. v. the County of Greenlee. The Company must pay the taxes assessed against it in 1911. In addition, the Company must pay 25% for attorney's fees, 12% interest on the principal, and 6% on the attorney's fees.

SANTA CRUZ COUNTY

John B. Rice, of San Francisco, has filed suit in the federal court, district of Arizona, against R. R. Richardson, of Patagonia, seeking to collect \$55,000 alleged to be due as commission on the sale of the Three R mine in the Patagonia district, from R. R. Richardson and A. E. Crepin to N. L. Amster.

YAVAPAI COUNTY

The old Octave mine, near Stanton, as soon as the debts of the old company are paid off, will resume development, as there is a fair equipment on the property. Years ago the Octave produced rich gold ore. The Schmidt group of claims has been sold. Over 3000 ft. of work has been done underground. Twenty-eight inches of \$40 ore has been found at a depth of 200 ft. in the Eureka mine, near Walker.

CALIFORNIA

During August the net production of oil from all counties of the State was 8,411,704 bbl. The Midway field increased from 2,692,001 to 3,079,989 bbl. compared with July. Net shipments were 7,495,099 bbl., and stocks

amount to 48,923,556 bbl. In the 16 oilfields there were 44 new rigs, 332 wells drilling, 382 wells idle, 64 completed, 5940 active, and 1164 idle producers. Twenty wells were abandoned.

The U. S. Geological Survey is carrying on studies in all parts of this state. A detailed geologic reconnaissance is being made of a large area covering the Inyo range and eastern slope of the Sierra Nevada, with special reference to the ore deposits. This is a continuation of work that was done last year and is in charge of Adolph Knopf. The area to be covered includes parts of the areas known as the Mount Whitney quadrangle, lying between latitudes 36°30' and 37° and longitudes 118° and 118°30'; the Bishop quadrangle, immediately north of the Mount Whitney; and the Ballarat quadrangle between longitudes 117° and 118° and latitudes 36° and 37°, all in Inyo county. The total area under this investigation approximates 6000 square miles. In addition, a special reconnaissance examination will be made by Mr. Knopf of the Bodie district of Mono county and the Darwin district of Inyo county. The Panamint valley, also in Inyo county, is to be examined in connection with a search for potash deposits. This search will include drillings by C. E. Watson in the hope of finding possible buried saline deposits and is under the direct supervision of Hoyt S. Gale. W. B. Hicks will make a preliminary chemical examination of the brines and the drilling cores in the field. The copper mines of the foothills district will be visited by B. S. Butler for the purpose of noting developments, but not with a view of issuing a geologic report. The oilfields come in for more detailed geologic mapping and studies by R. W. Pack and J. D. Northrop. This work is being done primarily for the purpose of classifying the lands, but will probably lead to the preparation of an economic report on the area studied. Mr. Pack will also visit the oilfields previously studied in order to keep in touch with developments and to make such further studies as he finds necessary.

A study of the geography, geology, and mineral resources of that part of California lying south of latitude 36°30' and west of a line drawn from the northeast corner of the San Geronimo quadrangle (longitude 116°30', latitude 34°30') to the northwest corner of the Holtville quadrangle (longitude 115°30', latitude 33°) and thence south to the international boundary, is being conducted by Robert T. Hill, who will prepare a general report of economic, educational, and scientific importance to cover the whole area. In northern California a detailed areal study of the Weaverville and Big Bar quadrangles is being made by J. S. Diller and H. G. Ferguson, geologists. These quadrangles lie between longitudes 122°30' and 123°30' west and latitudes 40°30' and 41° north. Work on the Weaverville quadrangle was begun last year, and the mapping of the geology of the Big Bar quadrangle will be commenced this season.

AMADOR COUNTY

The suit between the Kennedy Extension and Argonaut companies is still being heard at Jackson. On September 26, the examination of John W. Finch, of Colorado, by Judge C. H. Lindley of San Francisco, was especially interesting. The Fremont Mining Co. will probably increase its mill from 40 to 80 stamps.

BUTTE COUNTY

The South Banner Mining Co. held a meeting at Oroville on September 26, and the capital was increased from \$50,000 to \$250,000. It is probable that an English company will start operation near the property shortly.

INYO COUNTY

The Bishop Creek mine has been recently examined by R. F. Barry, who states that the mine has enough profitable ore to pay the expenses of developing more territory and placing the property on a paying basis. The west drift on the 300-ft. level has been extended 50 ft., and 5-ft. samples averaged \$18 per ton. The ore-shoot has no defined walls and is heavily mineralized. It will be necessary to install a 50-ton cyanide plant. Generally, the mine has been well opened.

NEVADA COUNTY

(Special Correspondence.)—The Brunswick Consolidated G. M. Co. held its meeting at San Francisco on September 25. J. W. Pew, the president, retired, and W. H. Oscanyon, of New York, was elected in his place, and A. J. Young, vice-president, retired, while R. Chester Turner was elected vice-president and general manager. The mine at Grass Valley is developing satisfactorily. It is at present worked through an incline shaft 1250 ft. deep, but a vertical shaft is being sunk from the surface, following a raise from the mine workings. This shaft will be 874 ft. vertical depth. The 20-stamp mill is working full time, treatment being amalgamation and concentration. A good recovery is made by this method. Concentrate is sold to the Pioneer Reduction Works of Nevada City.

Grass Valley, September 25.

PLUMAS COUNTY

The Copper Queen mine, 8 miles southeast of Genesee, has been bonded by J. R. Walker, of Salt Lake City, to a Utah company. A shaft is to be sunk 200 ft., equipment installed, and a road 5 miles long constructed.

SACRAMENTO COUNTY

The Natomas Consolidated of California had a gross

GENERAL VIEW OF SELBY SMELTER.

income of \$239,956 during August. Operating expenses were \$117,608, and interest on mortgages \$74,895, leaving a net profit of \$47,453. The net income for the first eight months of the current year totals \$868,587, which is \$174,962 more than for that period of 1912.

SHASTA COUNTY

The Mountain Copper Co. is shipping from Keswick 250 cars of ore per month. The copper ore comes from the Iron Mountain and Hornet mines, principally the former. It is estimated that the Company ships 12,500 tons of copper ore from this station every month to its smelter at Martinez.

SISKIYOU COUNTY

The Salmon River mineral district is described in the *Scott Valley Advance* of September 25. At the Cub Bear mine over 200 tons of high-grade ore is on the dump, and a long shoot has been developed. Charles Ritz is in charge. The Highland, under charge of Bert Mattern, is being actively developed, as is also the Homestake with John Boyle as manager. Underground work and installation of equipment is under way at the Hardscrabble and Big Cliff groups.

SOLANO COUNTY

As a result of the protracted litigation between the Selby Smelting & Lead Co. and the people of Solano county, the smelting company is now the owner of over 1900 acres of land near Benicia. This land consists of several of the largest farms, the Company having purchased them one by one in the past year. These farms all lie in the zone that is supposed to be damaged most by the smelter fume, and were owned by men who sued the smelting company for several years. Since selling, they have continued to live on the farms, leasing them from the Company. The commission, appointed a few weeks ago by the board of supervisors to investigate the damage done by fume from the Selby smelter, is busy collecting data concerning the composition of the air in the affected zone.

COLORADO

Press reports dealing with the coal miners' strike in Boulder, El Paso, Fremont, Huerfano, Las Animas, and Routt counties state that from 70 to 90% of the men are out. In 1912 there were 11,763 men employed in 115 mines, and over 8000 are out on strike. The annual coal output is about 9,000,000 tons. The union insists on its recognition. The Colorado Fuel & Iron Co.'s plant at Pueblo will probably shut down on account of coal shortage. About 4000 men are employed at the Minnequa plant. Mines and mills in the Cripple Creek district will be affected if the strike continues for any time, although the Portland and Stratton's mines have about three months' stock. Later reports state that men are returning to work, as many have no sympathy with the union, but it is too soon to say what the result will be. It is known that the union will make a hard fight.

There has been some rioting among the strikers, and Robert Lee, a marshal, has been shot by a Greek miner. 'Mother' Jones is much in evidence, as is usual when strikes are on in any part of the country.

CLEAR CREEK COUNTY

At the Capital mine, a large electric locomotive is to be installed for hauling ore. The company is busy above the 300-ft. level. Hummer & Son are mining a large body of ore. A promising vein has been opened in the Denver mine in East Argentine. Eastern and Denver people will probably work the Sporting Times mines on Alpine mountain.

PUEBLO COUNTY

The annual report of the Colorado Fuel & Iron Co. for the year ended June 30 shows surplus, after charges, of \$1,727,192, a decrease of \$74,036 from 1912, though a gain of \$476,520 over 1911. Gross earnings increased over 1912 by \$47,436, but increase in expenses overbalanced this gain. The Company paid 35% back dividends on its preferred stock, during the year, leaving 39% still to be paid. The Company earned 3% for the common stock after deduction of this extra payment on the preferred.

THE SAN JUAN

During August the Tomboy mill treated 11,000 tons of ore, yielding \$81,500, including bullion from 1500 tons of concentrate. The estimated profit was \$33,000.

The Brown Mountain smelter was blown in on September 26, and will employ 30 men, and start on a fair supply of ore. At the Mountain Top, the main north drift had been driven 455 ft. on the vein on September 22. The shoot was 323 ft. long at this point, being worth \$1.20 gold and 138.84 oz. silver per ton. Beyond this the ore was broken and irregular in value, but later was worth 65.57 oz. silver over 12 inches. No. 1 raise was up 136 ft., and at 35 ft. the ore assayed \$2.20 gold and 106.73 oz. silver per ton. A station will be cut at 150 feet.

The mines throughout the San Juan are busier than for two years past and ore shipments are increasing regularly.

TELLER COUNTY (CRIPPLE CREEK)

Gas was troublesome in many of the mines during the latter part of last week, and work was temporarily suspended. A mill site for the El Oro Gold Mining & Milling

Co. is being surveyed by Hills & Willis in Eclipse gulch. At No. 1 shaft of the El Paso company's Beacon hill estate, a station has been cut at 1170 ft. depth, and a drift is being driven on the main El Paso vein to a point below the shoot opened on the 1000-ft. level. It is proposed to 'sink' the South Burns shaft of the Acacia Gold Mining Co. 200 ft. by 'raising.' This will be done by cross-cutting from the American Eagles mine, 1450 ft. deep, to a point directly under the South Burns shaft, and then drive the raise.

IDAHO

CLEARWATER COUNTY

The dredge at Pierce was destroyed by fire, probably caused by a short-circuit, on September 25, and the loss is estimated at \$45,000, the insurance being \$10,000. The machine was built about three years ago, and has been the cause of litigation. R. P. Bailey, of Walla Walla, was overhauling the dredge for operation this fall.

SHOSHONE COUNTY

Figures obtainable from authoritative sources on the August production of the largest operating mines in the Coeur d'Alene show that the total tonnage shipped by 19 properties was 34,275 tons, according to the *Salt Lake Tribune*. Of this tonnage, the Federal Mining & Smelting Co. contributed 7682 tons; Bunker Hill & Sullivan, 6198; Hercules Mining Co., 3808; Snowstorm, 3211; Green Hill-Cleveland, 2227; Stewart, 2227; Hecla, 1899; Success, 1421; Tamarack & Custer Consolidated, 1284; Gold Hunter Consolidated, 1105; Interstate Callahan Consolidated, 1016; Ontario Mining Co., 962; Marsh, 323; Sierra Nevada, 259; Alice lease, 116; Hypotheek, 31; S. L. Shonts, 25; Knickerbocker, 22; and National, 20 tons.

The Federal properties produce lead, zinc, and silver, as do the Hercules, Green Hill-Cleveland, and Success. The properties producing only lead and silver are the Bunker Hill & Sullivan, Stewart, Hecla, Tamarack & Custer Consolidated, Gold Hunter, Ontario, Marsh, Sierra Nevada, Alice lease, Hypotheek, Shonts, and Knickerbocker. The Snowstorm and the National are producers of copper, silver, and gold. The above figures representing the production of the Green-Hill Cleveland and Marsh properties, show a curtailed output owing to suspension of operations for repairs.

On October 4, the Bunker Hill & Sullivan Mining & Concentrating Co. paid dividend No. 193, of \$65,400. This makes the total amount of dividends paid \$14,565,750.

MICHIGAN

HOUGHTON COUNTY

In spite of the injunction against the strikers picketing and annoying miners at the copper properties, there was an outbreak on September 25, but this was quickly quelled by the militia. The injunction granted by Judge O'Brien last week, was suspended by him on September 29, and there is great rejoicing among the strikers, and trouble is predicted when picketing is resumed.

MONTANA

DEERLODGE COUNTY

The Georgetown mining district and the Southern Cross mine are discussed in a paper presented at the Butte meeting of the A. I. M. E. by Paul Billingsley. The Georgetown mining district is situated about 20 miles west of Anaconda. It lies along the divide between the headwaters of Warm Springs creek, draining eastward, and Flint creek flowing west and north through the Philipsburg valley. On the western slope of the divide is the Southern Cross group. The ore deposits of the district may be conveniently classified into four types: (1) fissure veins in granite; (2) contact metamorphic deposits; (3) fissure veins in limestone; and (4) replacement bodies in limestone. The Granite-Bimetallic mines are the chief representative of the first class, and the Southern Cross is a characteristic replacement deposit in limestone. The latter property was located in 1866, and after many changes in ownership now belongs to the Anaconda Copper Co., which constructed a railroad to the mine. The ore, high in iron and desir-

able as a flux, is smelted direct at the Washoe smelter, so that the two great difficulties of the past, the long wagon haul and the refractory milling character of the ore, need not be contended with in the future.

SILVERBOW COUNTY

The Washoe smelter is to be shut down for two weeks for general repairs, which will reduce the copper output of the Butte district by about 10,000,000 pounds.

NEVADA

CLARK COUNTY

(Special Correspondence.)—Two cars of ore, containing 36 tons of \$400 and 32 tons of \$150 ore, respectively, were broken from the 600-ft. level of the Quartette mine and sent to the Selby smelter. The Cyrus Noble mill is now working full time. A shaft is being sunk at the north side of the Techatticup adit and will connect the workings at the 400-ft. level. This property produced a great deal of bullion years ago. A 50-ton treatment plant is to be built on the Silver Legion Estate. Good ore is being opened in the Eldorado Empire and Mineral Farm mines. Searchlight, September 29.

ELKO COUNTY

The main adit of the Nevada Bunker Hill Mining Co., at Bullion, is in 2028 ft., and during the last 50 ft. the vein of iron ore has changed to 8 in. of lead carbonate ore assaying 30% lead. Several other claims adjoining are being developed. Moe and Dougherty will construct an aerial tramway to convey ore from the lease to the Elko dump, where it will be loaded on wagons for the railroad.

HUMBOLDT COUNTY

Negotiations are under way for consolidation with the properties of the National Mines Co. of claims owned individually by stockholders in that concern and lying immediately east of West Virginia No. 1, now owned by the National company. The National vein is reported to have been found on this property in an adit, and while the rich ore found above has not yet been reached, the workings are none the less in good ore. In the National workings the famous ore-shoot has been traced 60 ft. on the 600-ft. level. The mine has so far produced about \$6,000,000.

LANDER COUNTY

(Special Correspondence.)—The Ruby Silver Mining & Development Co., which is operating the Estella and Betty O'Neal group of claims at Lewis Canyon, 12 miles south of Battle Mountain, has received returns from three carloads sent to the Western Ore Purchasing Co. at Hazen. The settlement sheets show that the average value of the 86 tons that was shipped was \$79 per ton, giving a total of \$6794 for the three carloads. An adit in the Topsy claim is in 345 ft., and the vein cut at 150 ft. is 5 ft. wide. At the bottom of a 105-ft. winze, 40 ft. farther in, the vein is 14 ft. wide, assaying \$50 per ton, mostly in silver, but with a little gold and copper. A drift was driven 30 ft. from 50 ft. depth in the winze and opened 24 ft. of ore, 3 ft. of which averages 800 oz. silver per ton. Sixteen feet farther in the cross-cut shows 14 in. of ore worth up to 2000 oz. per ton. Another adit is in 380 ft., and in another 50 ft. a raise will be driven to connect with the winze mentioned. The property has an up-to-date equipment.

Battle Mountain, September 22.

LYON COUNTY

From September 1 to 24, the drift on the middle level of the Douglas Hill portion of the Nevada-Douglas property averaged 7.1% copper. The drift is nearing the limestone area, which is looked upon as favorable.

NYE COUNTY

During the week ended September 27, the mines at Tonopah produced 11,503 tons of ore valued at \$272,690. In the Belmont, the Shaft, Favorite, Thanksgiving, Mizpah, Fault, and Belmont veins have been opening in an extremely satisfactory way. A winze is being sunk from the 600 to the 700-ft. level, the ore on the former level being from 18 to 20 ft. wide. Generally, the ore opened

on the 850-ft. level of the Extension is of better grade than on the level above. Two rock-crushers have been ordered for installation at the shaft. The Buckeye-Belmont has cut a vein in trachyte formation at 1200 ft. A new shoot of high-grade ore has been opened in a cross-cut above the 615-ft. level of the Montana mine.

Five years ago, Rhyolite had a population of about 6500 people, but at the present time it is stated to be practically deserted, although several pretentious buildings remain.

Bad weather has interfered with operations of the Railroad Valley Co., which is drilling for potash in the eastern part of the county. No. 3 hole is down 770 ft., 13/5 miles from No. 2 hole. No. 4 will be started in a few days.

(Special Correspondence.)—The Railroad Valley Co. has found gaylussite and saline clays in another well. Tonopah, October 2.

STOREY COUNTY

In the Gold Hill district, the Crown Point, Belcher, and there are over twenty companies operating mines, and the monthly payroll is about \$45,000. During the first half of the current year the various mines have shipped 60,259 tons to the mills which yielded \$624,210. Of this the Mexican produced 10,958 tons, yielding \$246,306.

In the Gold Hill district, the Crown Point, Belcher, and Yellow Jacket companies are now engaged in installing a pumping plant that will soon make available several additional levels below the present water-line, and activity in that locality will be greatly stimulated thereby. At the north end of the lode, the Comstock Pumping Association at the C. & C. shaft is doing effective work in preparing for the recovery of new levels below the 2500-ft. level.

During the week ended September 29, the water in the old Con. Virginia winze was lowered about 4 ft. below the 2500-ft. level, this being the first time since 1885 that the water has been below that point.

NEW MEXICO
SOCORRO COUNTY

(Special Correspondence.)—An ore-shoot has been cut at 650-ft. below the Ernestine mill adit, and the mill's capacity has been increased from 100 to 160 tons per day. The Socorro company shipped about 1.25 tons of gold and silver bullion to the mint last week. Three leases are in operation at the Oaks property. The Little Charlie mine is shipping 50 tons of \$20 ore per day. Work has been resumed at the Treasure mine. Machine drills are now employed in the Maud mine.

Mogollon, September 22.

All the mills in the Mogollon district are working full time, and the total output is valued at over \$150,000 per month.

UTAH
BEAVER COUNTY

The geology and ore deposits of the San Francisco region of this county have been detailed by B. S. Butler in U. S. Geological Survey Professional Paper 80. This area is in the north-central part of the county and covers about 200 square miles. It is about 180 miles southwest of Salt Lake City. Frisco and Newhouse are the only important towns in the district. The altitude on the plains is from 5250 to 6500 ft., while Quartzite hill rises abruptly to 9725 ft. The climate is temperate, and vegetation and water are scarce. The mountain ranges consist of a central mass of granite, with beds of limestone, sandstone, and shale, having an easterly dip, forming the southern portion, and limestone and sandstone the northern portion. The ore deposits are in quartz monzonite, sedimentary rocks, and lava flows. To the end of 1910 the district had produced the following:

Ore, tons	995,632
Gold, ounces	15,015
Silver, ounces	15,305,624
Copper, pounds	27,935,883
Lead, pounds	328,011,019
Zinc, pounds	4,571,424
Total value	\$26,905,090

GRAND COUNTY

A brief report on the oil and gas development near Green river, in this county, has recently been issued by the U. S. Geological Survey as a result of a geologic investigation made last year by Charles T. Lupton, M. W. Ball, and R. V. A. Mills, of the Survey. An area of about 300 square miles was examined, the object being to determine if this area, in which considerable drilling for oil and gas has been done, contains any reservoirs of these materials. In the area examined in detail, the geologists found no anticlines or domes in which large quantities of oil or gas might be expected to collect. Traces of oil and small pockets of gas have been found in some of the

THE 'CITY' OF MOGOLLON, NEW MEXICO.

wells, but in quantities so small as to afford only slight encouragement.

JUAB COUNTY

Ore shipments from the Eagle & Blue Bell mine in August were worth \$46,700, and operating expenses \$13,700. Copper ore, assaying from 20 to 30%, is being mined on the 2400-ft. level of the Grand Central. The main shaft will be retimbered in the upper portion early in October, making the top 400 ft. completely new. Lessees on the 450-ft. level of the Opohongo are mining rich copper ore, while those at the Godiva mine are opening high-grade lead-silver and zinc ore.

SALT LAKE COUNTY

It is proposed to increase the Alta Consolidated Mining Co.'s shares from 300,000 to 500,000, and to place the new ones in the treasury. There is \$13,259 owing the bank, and this will be paid, besides buying more equipment. Since work started, development has covered 3233 ft., from which 2462 tons of ore was recovered yielding \$57,115. Ore shipments during the summer have been disappointing, but are now of better grade. The new railroad is expected to reduce freight costs soon. Receipts during the term August 1, 1911, to September 22, 1913, were \$122,930. Assets are \$313,404 and actual liabilities \$13,259.

SUMMIT COUNTY

A reservoir of 40,000,000 to 50,000,000-gal. capacity is being constructed at the mouth of the Snake Creek tunnel. The present flow of the tunnel is approximately 4000 gal. of water per minute. The tunnel is in 6700 ft. and progress is being made at the rate of 12 to 15 ft. per day. The purpose of this reservoir is to conserve the flow of water from the tunnel, guaranteeing a steady and maximum flow for ultimate hydro-electric power purposes, while it will serve as a steady supply for irrigation purposes during dry seasons. The revenue from the water should be an important source of income for the company. Material for constructing the reservoir will consist of that extracted from the tunnel.

WASHINGTON

The coal resources of Cowlitz River valley, Cowlitz and Lewis counties, are described in Bulletin 531-L, by A. J. Collier, of the U. S. Geological Survey, after a brief investigation. Along the Cowlitz river, northward from its junction with the Columbia, lies an area of coal land 30 miles long and 15 miles wide. This field is probably continuous with that about Centralia and Chehalis. The prevailing rocks are soft sandstones, lying horizontally, and which locally contain beds of coal. An exposure of coal on the Coweman river, which enters the Cowlitz from the east at Kelso, shows the following: sandstone, 20 ft.; coal, 1 ft.; sandstone, 3 ft.; coal, 1 ft.; shale, 4 ft.; and coal 6 in. The Anchor mine, $3\frac{1}{2}$ miles north of Kelso, has been shut down for several years, although it contains fair seams of coal. The Coal Creek mine has produced coal containing from 27.11 to 30.05% fixed carbon. The Carbondale mine, 2 miles from Castlerock, is the only mine in the district producing coal, and the seam has been followed down the slope for about 1000 ft. The Lowell, Idleman, Red Ash, and others are abandoned.

FERRY COUNTY

The mineral deposits of the Covada mining district, lying within the southern half of the Colville Indian Reservation, are described in Bulletin No. 16 of the State Geological Survey, by Charles E. Weaver. The area of the district is about 40 square miles, and generally it is easy of access by wagon-road, the direct distance from Republic being 35 miles southeast. The topography of Covada district is characteristic of northwestern Washington, the entire drainage finds its way to the Columbia river, the lowest elevations are from 1200 to 1300 ft. above sea-level, there is direct evidence of glaciation even on the high mountains, and there is plenty of timber growing throughout the district. The rocks entering into the formation of the district are composed of silicious slates, slaty schists, quartzites, argillaceous quartzites, and dolomitic limestones. Mining activity in the district is of comparatively recent date, being commenced in 1898. The majority of the ore-bodies occur in well defined fissures, chiefly within the granodiorite mass or in the Covada metamorphic formation not far from the contact. In a number of instances, the veins consist of impregnated country rock along zones of fracturing. The vein matter consists of quartz and sometimes calcite, containing silver and lead with smaller quantities of gold, copper, and antimony. The commercial value is in the silver. There are at the present time approximately 200 claims in the district, 16 of which are patented.

CANADA

BRITISH COLUMBIA

The Canadian Consolidated Mining Co. paid a dividend of \$2 per share on September 30. The amount distributed is \$110,000, making a total to date of \$1,125,061.

ONTARIO

On the 200-ft. level of the Beaver Auxiliary mine at Elk lake, two to three inches of calcite assaying 6000 oz. silver per ton has been opened. La Rose Consolidated will pay \$187,500 on October 20, making dividends of \$4,099,185 to date. During August the McKinley-Darragh mill produced 212,098 oz. silver, of which 69,436 oz. came from the Sav-

age property. The 190-ft. level of this property is producing a large quantity of ore, but the heaviest output came from No. 42 vein, a new orebody in the 'swamp' portion of the property. During August, the Buffalo Mines mill treated 5971 tons of ore yielding 115,742 oz. silver, while 413,717 oz. was paid for during the period.

The shoot on the 100-ft. level of the Tough-Oakes mine is producing some rich ore, and hand sorting is being done. The second-class ore goes to the stamp-mill.

YUKON

The Engineer mine, near Atlin, is producing rich ore, which is being crushed in a 2-stamp mill. Since July 1, the average clean-up of amalgam has been 100 oz. per day. It is stated that 100 stamps may be erected next year.

MEXICO

JALISCO

The Tonopah Belmont Development Co., of Nevada, has not completed a deal pending for the purchase of the Zuloaga, Condesa, and Rosario mines in the Bolaños district. Unsettled conditions in Mexico was the main reason for allowing the business to lapse.

MEXICO

The El Oro Mining & Railway Co. treated 24,180 tons of ore and 13,200 tons of tailing in August, yielding a total of \$176,670. The profit, including \$9000 from the railway, was \$61,650. The 40-stamp mill of the Mexico Mines of El Oro treated 13,450 tons yielding \$138,610. The profit was \$82,370. The report of this Company, operating at El Oro, covers the year ended June 30, 1913. There was mined and treated a total of 158,630 tons averaging \$8.23 gold and 5.9 oz. silver per ton. The 40-stamp mill averaged 11.15 tons per stamp day, the bullion produced being valued at \$1,669,540, equal to 88.99% recovery. The ore from the lower levels is less amenable to cyanidation than the oxidized ore, and lower extractions will result. Total working costs were \$4.12 per ton. Ore reserves total 403,100 tons. The year's profit was \$960,000, and dividends amounting to \$4.32 per share were paid, equal to \$777,600.

SONORA

(Special Correspondence.)—Judging by the number of small properties resuming operations, either through lessees or their companies, mining conditions throughout the northern portion of the state are gradually getting better. Especially true is this condition in the northeastern portion of the state, and in the Nacozari district, where, during the past month several small properties have renewed operations after being idle since the first of the year. Lessees have been getting a chance to work some rich properties and some of them are doing well.

The Santa Maria mine, situated near the rich Chispas property of the Pedrazzina company, is now opening satisfactorily. The shaft is down 455 ft. and the Espiritu Santa vein is expected to be cut before the 500-ft. level is reached. Drifts on the various levels, from the 100 to 400-ft., are showing well. Twenty men are employed at present. R. B. Phillips is in charge of the operations. The Chispas mine will probably not resume operations for some time, as it is understood that orders have recently been received from the Paris offices to sell all supplies now on hand.

Cananea, September 27.

The three-compartment shaft of the Moctezuma Copper Co., at Pílares, has opened good ore at 1100 ft., and the management has decided to continue sinking to the 2000-ft. level. This will be the deepest shaft in the state of Sonora. A larger hoisting station is being cut on the 700-ft. level of the Guadalupe three-compartment shaft. It will be equipped with three-ton skips and a large electric hoist. It is the ultimate intention of the Company to make the Guadalupe the main hoisting shaft. The Nacozari Consolidated Copper Co. is now excavating ground for its 100-ton mill. The adit in this property is showing better ore as it is driven into the 'red' hill.

Schools and Societies

The AMERICAN INSTITUTE OF MINING ENGINEERS, at a directors' meeting held in New York on September 22, appointed the following committee on Petroleum and Gas: Anthony F. Lucas, chairman; Mark L. Requa, vice-chairman; David T. Day, vice-chairman; William N. Best, vice-chairman; Leonard Waldo, secretary; Ralph Arnold, Frederick G. Clapp, Edwin T. Dumble, Richard S. Haseltine, C. Willard Hayes, Philip W. Henry, John Langton, William B. Phillips, William L. Watts, L. C. White, and William A. Williams. A meeting of the above committee will be held on October 15 to complete the organization. The meeting will be preceded by a dinner at the Engineers' Club.

The COLLEGE OF ENGINEERING OF THE UNIVERSITY OF ILLINOIS reports the following new appointments to its staff, effective September 1, 1913, C. R. Richards being acting dean of the College. L. H. Provine, as professor of architectural engineering, graduated from the University of Illinois. L. A. Harding, as professor of experimental mechanical engineering, graduated from the Pennsylvania State College. A. C. Willard, as assistant professor of heating and ventilation, graduated from Massachusetts Institute of Technology. Percy Ash, as assistant professor of architectural design, graduated from the University of Pennsylvania. W. C. Titcomb, as assistant professor of architecture, graduated from Harvard College. J. I. Parcel, as assistant professor of structural engineering, graduated from Westfield College. W. M. Wilson, as assistant professor of structural engineering, graduated from Iowa State College. E. A. Holbrook, as assistant professor of mining engineering, graduated from the Massachusetts Institute of Technology. P. S. Biegler, as associate in electrical engineering, graduated from the University of Wisconsin. S. O. Andros, as associate in mining engineering. For the past two years Mr. Andros has been field assistant in the cooperative mining work which is being carried on here by the United States Bureau of Mines, the State Geological Survey, and the Department of Mining Engineering. J. H. Forsythe, as instructor in architecture, graduated from the University of Pennsylvania in 1908 and received the degree of master of architecture from Harvard University in 1913. A. B. M. Corrubla, as instructor in architecture, graduated from Washington University in 1911 and received the degree of master of science in architecture from Massachusetts Institute of Technology in 1913. A. R. Knight, as instructor in electrical engineering, graduated from Ohio State University. Rufus Crane, as instructor in general engineering drawing, graduated from Middlebury College in 1909 and from the Massachusetts Institute of Technology. H. W. Waterfall, as instructor in machine design, graduated from the Massachusetts Institute of Technology. F. C. Torrance, as instructor in mechanical engineering, graduated from Cornell University. H. E. Babbitt, as instructor in municipal and sanitary engineering, graduated from the Massachusetts Institute of Technology. Harry Gardner, as instructor in theoretical and applied mechanics, graduated from the University of Wisconsin in 1905 and received the degree of master of science from the University of Kansas in 1911. Alexander Vallance, as instructor in theoretical and applied mechanics, graduated from Ohio State University. L. E. Young, as part-time instructor in mining engineering while carrying on graduate work in economics, graduated from Pennsylvania State College. R. B. Keller, as first assistant in the engineering experiment station, department of railway engineering, graduated from Purdue University. Sebastian Karrer, as assistant in physics, graduated from the University of Washington. B. L. Bowling, as assistant in the cement laboratory in the department of civil engineering. J. B. Nathanson as part-time assistant in physics, graduated from the Ohio State University in 1912 and received the degree of Master of Arts from the University of Illinois. J. H. Belt, as research fellow in the engineering experiment station, department of electrical engineering, graduated from the University of Illinois. Julian Montgomery, as re-

search fellow in the engineering experiment station, department of theoretical and applied mechanics, graduated from Grayson College in 1908 and from the University of Texas. R. B. Pogue, as research fellow in the engineering experiment station, department of railway engineering.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

E. B. KIRBY was in New York recently.
W. J. LORING visited Plymouth this week.
GEORGE H. GARREY has returned to New York.
R. B. MORAN has returned to San Francisco.
C. W. MERRILL has gone to Detroit and Toronto.
B. SNELLING ROBINSON has been in New York City.
H. G. NICHOLS has returned to London from the United States.
VICTOR E. TULL, of Seattle, is in San Francisco for the winter.
JUAN FELIX BRANDES is at the Royal Societies Club, London.
C. B. LAKENAN was in New York and has returned to Nevada.
WILL L. CLARK was in New York City last week, and has returned to Arizona.
ROBERT M. RAYMOND passed through San Francisco returning from Oroville.
C. C. BROADWATER has returned to San Francisco from London and New York.
H. N. LAWRIE is in New York, where he expects to remain for about three months.
COURTENAY DE KALB has returned to Tucson from a trip through northern Mexico.
CHARLES HAYDEN has gone to visit the copper properties with which he is associated.
F. L. COLE has returned to Shanghai from an examination of phosphate deposits in Indo-China.
P. H. HUNT will soon return to Redlands, California, from Charcas, San Luis Potosi, Mexico.
J. F. MCCLELLAND is at Murray Bay, Canada, and expects to return to New Haven about October 1.
WILLIAM MALONEY is the territorial inspector of mines for the Nome and Fairbanks districts of Alaska.
COLIN TIMMONS has removed from Denver to Dunton, Colorado. He is manager of the Emma gold mine.
H. C. MILLER, until recently with Daniels & Osmont, San Francisco, has opened an office at Bishop, California.
J. A. L. HENDERSON has returned to London from Canada, where he attended the International Geological Congress.
R. H. RICHARDS and WALDEMAR LINDOREN were in New York last week to attend the directors' meeting of the A. I. M. E.
TADASU HIKI, professor of mineralogy in Kyoto University, is in New York, where he expects to remain for some months.
JOHN T. REID has recently been appointed general manager for the Buffalo Valley Gold Mining & Leasing Co., at Anking, Nevada.
H. O. HANKE and G. W. LAMBOURNE, of the Daly-Judge company, have returned to Salt Lake City from an extended visit to the mine at Park City.
JAMES BROWN and ARCHIBALD STARK have returned to Spain after traveling along the west coast of South America and through the United States.
JOHN ASHWORTH, of Manchester, England, passed through New York recently in returning from the International Geological Congress at Toronto.
HENRY H. ARMSTEAD and ALEX. SMITH COCHRAN, of New York, are in Guanajuato, Mexico, making an inspection of the properties of the Golmena Mining Corporation and the Mexican United Company.
STANLEY C. SEARES, who recently resigned as general manager for the Utah Apex M. Co., to enter consulting practice, is to be married on October 8 to Mrs. ROBERT HOLMES OFFICER at Salt Lake City.

New York Metal Market Review

The striking feature of September was the strong statistical position of copper, which made 17c. per pound again a reality for Lake, with electrolytic nearby at 16.87½c. delivered, 30 days. Throughout most of the month the market was quiet, for the excellent reason that consumers had provided for their needs. The sold-up condition of the big agencies was proof of this. Lead declined steadily in strength and in the latter part of the month lower prices were indicated. In spelter there was no great amount of business and quotations became lower. Antimony continued dull and neglected. The consumption of tin was fair, but except for intermittent buying the market was quiet and prices declined. Aluminum was practically without action, at steady prices, awaiting the new tariff.

COPPER

The average price paid for copper by the brass mills in the Naugatuck valley, in August was 15.62½c., as against 14.75c. in July. In the last few days of August and all September the market gained steadily in strength. September 2, quotations were 16.25c. cash, for Lake, and 16.12½c. cash, New York for electrolytic. At this time the higher prices were ascribed chiefly to foreign influences, although there was a fair amount of domestic business. Throughout the month the strike situation in the Lake Superior region was a bull influence. The most important feature of the month was the Copper Producers' statement for August, which showed a heavy reduction in stocks and that only 38,314,037 lb. of metal, or a little more than the quantity required for two week's domestic consumption, was on hand August 31. If anything was needed to sustain the market the statement supplied it and prices at once advanced—electrolytic to 16.62½c. cash, New York, and Lake to 16.87½c. cash. Meanwhile buying became active, some of it for deliveries as far ahead as December. Predictions became many that copper would advance to at least 17c. before the end of the month. It did. Toward the middle of the month activity sagged off, but the strong statistical position, the strength abroad, the continuance of the Lake strike and a real scarcity of copper for prompt delivery upheld the market and on September 16, prices advanced to 16.87½c. cash, for Lake, and 16.75c. cash, New York, or 16.87½c. delivered, 30 days, for electrolytic. One foreign influence of a supporting character was a strike on the Rio Tinto railroad. Up to September 24, the market was quiet, but strong, and on September 19, Lake advanced to 17c. cash, New York. Some small resale lots which had been offered at ¼c. lower had been taken, and then 17c. became the lowest price. The feature at this time was the sold-up condition of the big agencies so far as early delivery metal was concerned. Except in a small way, September and October copper were not to be had. Near the close of the month the market was strong despite the absence of buying and there was every promise of it holding its position. Exports up to September 24 were 25,131 tons. The total exports in August were 34,722 tons. In the eight months of 1913 there were 258,454 tons, an increase of 29,726 tons, as compared with the same period last year. The price of Lake by September 26 had softened to 16.75c. and that of electrolytic to 16.62½c. Exports to September 27 were 26,819 tons.

SPELTER

The market was quoted at 5.90c. New York, and 5.75c. St. Louis, until September 16, when there was a decline of about 10 points, making about 5.80c. New York, and 5.65c. St. Louis, the quotations. In the days following, a weaker tendency developed and the prices mentioned could undoubtedly have been shaded if the right seller had been approached. Early in the month the demand was mostly for high-grade material for brass mill use. The reduction in price caused a little more activity in the cheaper grades, but at no time was there any great amount of business. An interesting fact which came to light was that foreign spelter had been offered in the New York market, but had found no takers, not only because consumers were not

eager to buy, but because some of them were unfamiliar with the qualities of the foreign metal and did not choose to buy, especially when there was no great inducement in the matter of price. Quotations on September 26 were 5.70 to 5.75c. New York, and 5.50 to 5.55c. St. Louis.

LEAD

From the first of the month until September 24 the New York quotation of the largest lead interest was 4.75c., but on the latter date the market was weak and it was freely predicted that a decline was soon to be expected. St. Louis prices gave tangible evidence of the growing weakness, quotations dropping first to 4.65c. (from 4.67½c.), then to 4.62½c. and then to 4.60c., with every indication of a still lower figure. The settlement of the strike in the lead mining district early in the month brought about an easier feeling, as was to be expected, while business also dropped off and the market continued dull until near the end of the month when this report was written. Lead could be had at 4.65c., New York, and 4.50c., St. Louis, on September 26.

ANTIMONY

Throughout September antimony was neglected, the market listless and without interest so far as new developments were concerned. The range of prices was unchanged at 7.75 to 8c. for Hallett's, 8.35 to 8.40c. for Cookson's, and 7.37½ to 7.50c. for Chinese and Hungarian grades. The heavy imports previously referred to continued, and most of the metal went into bonded warehouses to await the enactment into law of the new tariff. Some authorities stated that approximately a year's supply of the metal was stored in this manner. Others declared there was no profit in the prevailing prices and that either sales were being made of metal imported fully two years ago or sales were being made at a loss.

PIG TIN

As was the case in August, the range of tin prices in September was within rather narrow limits. September 2, sales were made at 43.05c., September 9 at 42.50c., September 16 at 42.75c., and September 23 at 41.75c. Buying, as usual, was intermittent, one of the best days being on September 8, when 350 tons was taken. Following this flurry, quiet prevailed and the pressure to sell far exceeded the inclination to buy. Consumption was fair in September, and toward the end of the month buying was looked for in good volume, but it had not materialized up to the 24th. Most of the interest in the third quarter of the month was in futures, but in these there was no business which could be called large. Supplies at this time were ample, but fairly well concentrated in a few hands, and these were not over anxious to sell at the prevailing price—a few points under 42c. Arrivals up to September 24 were 3069 tons and there was afloat on that day 3040 tons. The total visible supply August 31, 1913, was 11,261 tons, which was 24 tons below that of August 31, 1912. Tin arrivals to September 27 were 3469 tons and there was afloat September 26, 2665 tons.

ALUMINUM

Of this metal little is to be said. But slight interest was taken in it, at least up to September 24. What there was was mostly in futures. Prices for prompt domestic up to that date, underwent no change. It was quoted at 21.50 to 22.50c. The range of foreign aluminum in bond came down a little and 18 to 18.25c. was quoted. The attitude of most consumers was one of waiting for the new tariff.

The United States Civil Service Commission announces an open competitive examination for junior chemist qualified in fuels, on October 8 and 9. From the register of eligibles resulting from this examination, certification will be made to fill a vacancy in this position in the Bureau of Mines, Washington, D. C., at a salary of \$1020 per year, and vacancies as they may occur in positions requiring similar qualifications in other branches of the service. Competitors will be examined in mineralogy, translation from French or German technical works, physics, chemistry, and general education.

The Metal Markets

LOCAL METAL PRICES

San Francisco is not a primary market for the common metals except quicksilver. The prices quoted below therefore represent sales of small lots and are not such as an ore producer could expect to realize. Ore contracts usually call for settlement on the basis of Eastern prices, less freight and treatment charges. The prices quoted are in cents per pound, except in the case of quicksilver, which is quoted in dollars per flask of 75 pounds.

San Francisco, October 2.			
Antimony.....	12-12½c	Quicksilver (flask).....	\$39.50
Electrolytic Copper.....	17½-17½c	Tin.....	46-47½c
Pig Lead.....	4.85-5.80c	Spelter.....	7½-7½c
Zinc dust, 1400 lb. casks, per 100 lb., small lots \$9.50-9.75; large \$7.50-8.50			

EASTERN METAL MARKETS
(By wire from New York.)

NEW YORK, October 1.—The copper market is firm but somewhat easier. Standard, spot, and October copper is quoted at from 16 to 16.50. November and December 16.25 to 16.50; electrolytic 16.87, and Lake 17; casting 16.52 to 16.75. The foreign fortnightly statistics, as reported in London, show that the stocks have decreased 1513 tons. The Copper Producers' report will appear on October 8, and it is predicted that it will show a decrease of the stock on hand of from ten to fifteen million pounds. The London market closed with spot at £74 and futures £73 15s. Lead and spelter are weak. Tin is quiet with spot, October, and November at 41.12½, and December 41.15.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

Date.	Average week ending			
Sept. 25.....	61.62	Aug. 20.....	59.16	
" 26.....	61.87	" 27.....	59.46

June	61.29	59.03	Dec.	63.38

Notwithstanding the continued scarcity of business during the greater part of the week, or perhaps on account of it, the tone of the market was decidedly more cheerful, and, apart from a slight reaction on the first day, the trend of prices was distinctly upward, according to Samuel Montagu & Co., of London, on September 11. The money stringency in India, combined with the large drop in the holding of silver in the currency reserves, has resulted in a flow of buying orders from Indian speculators anxious to cover their former sales, and prices today have further improved to 27¼d. for cash and 27 15/16d. for two months. The prospects for the immediate future are dependent to a large extent on whether China becomes a free seller or not, as, apart from the large accumulations under her control, supplies are limited.

COPPER

Quotations on copper as published in this column represent average wholesale transactions on the New York market and refer to electrolytic copper. Lake copper commands normally from 1-5 to 1-4c. per lb. more. Prices are in cents per pound.

May	16.03	15.42	Nov.	17.31
June	17.23	14.71	Dec.	17.37

The copper market was quiet during last week and weaker at its close. On September 22 the nominal quotation was 17c. per pound, and it was expected that brisk buying would

soon send it above this figure. The expected buying did not develop, however, and though October copper, which was scarce, was firmly held, the metal was available for more distant delivery at a lower figure. During the middle of the week, concessions were made. By September 26 some of the dealers in 'second hands' were selling small lots at 16½c., though the larger agencies were still quoting 16½c. without eliciting much business. Exports for the week ended September 25 were reported at 6783 tons, making 26,819 tons exported since September 1, as compared with 22,798 tons in the same period last year.

Prophecies as to the change in stocks this month are now in order, and a further decrease of 5,000,000 to 10,000,000 lb. is the expectation of one of the producers. Consumers have not yet been heard from. D. C. Jackling is reported to have said that the September production of Utah Copper will exceed the August figures by 1,000,000 lb. No one seems to know what the Lake output has been during the past month. If the Washoe smelter shuts down for a week, as announced, it will cut 5,000,000 to 7,000,000 lb. off next month's output.

LEAD

Lead is quoted in cents per pound or dollars per hundred pounds, New York delivery.

QUICKSILVER

The primary market for quicksilver is San Francisco, California, being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 76 lb., are given below:

Week ending		Sept. 17.....	39.50

May	41.75 40.25	Nov.	41.50
June	41.30 41.00	Dec.	39.75

TIN

New York prices control in the American market for tin, since the metal is almost entirely imported. San Francisco quotations average about 5c. per lb. higher. Below are given average monthly New York quotations, in cents per pound:

Monthly averages.					
	1912.	1913.		1912.	1913.

OIL PRODUCTION IN 1912

A preliminary statement by the U. S. Geological Survey shows that California produced 86,450,747 bbl., and Wyoming increased from 186,695 to 1,572,306 bbl. compared with 1911. Higher prices were the rule in 1912, except in California, and even in that state, despite the great production, there was no considerable decline. The average world price in 1912 was 74c. per barrel, against an average of 61c. in 1911. Stocks of crude oil decreased 10% in 1912, resulting in stimulation of prices and increased activity in drilling all over the East. The decrease in stocks is ascribed to improved export conditions and increased capacity of the refiners to take care of the crude oil. While stocks did not decrease in California, expanded consumption checked increased storage of oil. The total production of the United States was 222,449,391 bbl., equal to 63.25% of the world's output.

GOLDFIELD CONSOLIDATED REPORT	
The report of the general manager, Albert Burch, of the Goldfield Consolidated Mines Co., for August contains the following:	
Development, feet (cost per foot, \$5.40).....	3,094
Ore treated, tons	32,096
Net realization	\$198,784
Costs.....	Perton
Mining:	handled. Total.
Stoping	\$2.78
Development	0.52
	\$3.30
Shipping expense	\$8.21 0.34
Dump moving	1.00 0.05
Transportation	0.07
Milling	1.85
Marketing	0.05
General expense	0.27
Bullion tax	0.09
Construction	0.01
Total costs	\$6.03
Miscellaneous earnings	0.04
Net costs	\$5.99

During the month, driving on No. 7 level of the Combination mine was continued on the vein previously cut by a diamond-drill, but no pay-ore was opened till about the end of the month. The 136-BX sill was extended and produced 161 tons of \$29 ore. The 3-R sill in the Mohawk was extended and produced 28 tons of \$12 ore, and an extension of the 170-CX sill produced 100 tons of \$15 ore. The 139-X cross-cut and 141-X drift on the first level, about 400 ft. north of the shaft, produced 153 tons of \$17 ore, and the drift continues to look promising. New stopes are being gradually started in the 202 territory, between the first and second levels southwest of the shaft, and five are now in operation, producing a good tonnage of moderate grade ore. An extension of the 241 drift in the Laguna produced 104 tons of \$6 ore, and the drift has probably reached the northern end of the orebody. Stoping, which has been commenced above the drift, produces a much better grade of ore than was obtained from driving. No important developments of pay-ore have resulted from the month's work at the Clermont-Jumbo. The 916 cross-cut mentioned in last month's report was continued across the vein, which was proved to be 40 ft. wide, but no ore of a shipping grade was found at this point.

THE Seoul Mining Co., operating in Korea, will pay a dividend equal to 25% on the capital stock outstanding on October 16, the result of operations for the first half of 1913.

Current Prices for Ores and Minerals

(Corrected monthly by Atkins, Kroll & Co.)

The prices are approximate, subject to fluctuation, and to variation according to quantity, quality, and delivery required. They are quoted, except as noted, f.o.b. San Francisco. Buying prices marked *.

	Min.	Max.
Antimony ore, 50%, $\frac{1}{2}$ ton	*\$22.00	\$25.00
Arsenic, white, refined, $\frac{1}{2}$ lb	0.03	0.03 $\frac{1}{2}$
Arsenic, red, refined, $\frac{1}{2}$ lb	0.08	0.08 $\frac{1}{2}$
Asbestos, chrysotile	100.00	350.00
Asbestos, amphibole	5.00	25.00

The Iron Ranges of Minnesota

*The first mention of iron-bearing formation in Minnesota is by Norwood in 1852, but it was not until 1875 that there was any record of work being done to establish the economic value of the district. In this year A. H. Chester examined the Missabe range from Embarrass lake eastward to Birch lake. In the greater portion of the district examined, the formation is highly magnetic, and has never produced bodies of merchantable ore. Shortly afterward attention was almost wholly diverted from the Missabe by the discovery of ore on the Vermillion range.

In the early eighties George C. Stone succeeded in interesting Charlemagne Tower in the ore deposits on the Vermillion range near Tower. The first shipment of ore was made in 1884. In 1886 the whole property, including mines, railroad, docks, and land grant, was sold to the Minnesota Iron Co., and later; on the organization of the United States Steel Corporation, became a part of the holdings of that corporation. The first mine to be developed near Ely, 21 miles east of Tower, was the Chandler, which began shipping in the fall of 1888. Since then the Pioneer, Zenith, Sibley, and Savoy have been opened in what is known as the Ely trough. A new mine, called the Section 30, is being worked on another trough three miles east of Ely.

On the Missabe range, ore was discovered in the fall of 1890, near the present Mountain Iron mine, by the Messrs. Merritt of Duluth, and in the fall of the following year on the Biwabik property by the same men.

The Cuyuna range was located from the results of magnetic work done by Cuyler Adams about the year 1895. Very little was done, other than magnetic research work, until the year 1904, when the first drilling was started in Section 16, Township 46, Range 28, about a mile south-east of Deerwood. The first shipment of ore from the Cuyuna range was made in 1911 from the Kennedy mine.

Minnesota furnishes yearly about three-fifths of the iron ore produced in the United States, the shipments during 1912 amounting to 34,197,501 tons.

	Tons.
Missabe range	32,047,409
Vermillion range	1,844,981
Cuyuna range	305,111
Lake Superior district	48,221,546

Mineral Production of Quebec

The total mineral production of the province of Quebec during the year 1912 reached a total value of \$11,187,110, according to the 'Report on Mining Operations' by the Department of Colonization. These figures represent the revised compilation of the returns received direct by the Quebec Mines Branch from the producers. In the previous year the value of the products of the mines and quarries was \$8,679,786. There is, therefore, recorded an increase of \$2,507,324 for 1912, or a proportional increase of 28.9 per cent.

The collecting of mineral statistics is done as carefully as possible, and a list of producers of nearly one thousand names has been compiled. But it must be understood that, in spite of all the care exercised, the figures which are given are not complete, more especially as regards structural materials. The figures represent strictly the compilation of the figures received by the Quebec Mines Branch direct from the producers.

Only a small proportion of the metallic minerals enters into the total figures of the mineral production of the province of Quebec. In 1910 they only represented 2.16%; in 1911 this proportion increased to 3.17%, whereas in 1912 it reached 6.09%. This is insignificant when compared with Ontario, where in 1912 the metallic minerals made up 74% of the total mineral production of the province. As it was pointed out in the preceding report, practically the total mineral production of the province of Quebec is from the old settled portions of the province, but as the same geological conditions prevail in the northern part of Quebec as in northern Ontario, it is quite justifiable to foresee developments of the mineral industry in the northern parts of Quebec in the near future, owing in part to the active movement of railway construction which will open up vast areas. By the National Transcontinental, direct communication will soon be established between Quebec and the Abitibi region, and it is expected that within two years the North Railway will be open for traffic between James bay and the Transcontinental, following the valleys of the Nottaway and Bell rivers. It is true that the conditions in that part of the province are rather trying for the prospector. For, although the underlying rocks belong to Archean formations, which in other parts of Canada have proved mineral bearing, still it is a fact that all the

region lying north of the height of land was at the close of the glacial period, submerged under an immense sheet of water in the bottom of which was deposited a heavy burden of clays, silts, and sands, which now cover the rocky floor of the ancient lake. However, the strong current of colonization which is now being directed toward these regions, which are eminently fitted for agriculture, will doubtless bring about mineral discoveries which will help to increase the proportion of metallic minerals produced in the province of Quebec.

Increasing the Capacity of Slime Thickeners

Slime settlement has received much study at Anaconda, and in the August *Bulletin* of the American Institute of Mining Engineers is an exhaustive account of the experimental work, by Ralph Hayden. Among other points of interest, he shows that the depth of Dorr thickeners can be greatly decreased without seriously lessening the capacity. For example, a 3-ft. tank has 85% of the efficiency of a 9.7-ft. tank when operating at 98% efficiency. Similarly, a 2-ft. tank has about 85% of the capacity of a 3-ft. tank. To take advantage of this situation in existing plants, the Dorr Cyanide Machinery Co. is furnishing trays for placing in tanks of the old style, whereby in one case an 85% increase in capacity was realized, with the same floor space and head room previously occupied.

Costs at the Hollinger mine, Porcupine, during the month ended August 12 were as follows (per ton):

Prospecting	\$0.009	Plant alterations, etc..	0.041
Mining	1.557	Boarding-house, etc...	0.272
Development	1.300	Administration, gen-	
Treatment	1.395	eral, etc.....	0.628
Marketing bullion ...	\$0.072		
		Total	\$5.274

OIL PRODUCTION from shale in Scotland is about 250,000 tons annually, and is highly satisfactory as a fuel. The shales in New South Wales, Australia, yield about 120 gal. of oil per long ton subjected to distillation.

ELECTRIC BLASTING is to be used underground at the Meyer & Charlton mine on the Rand, as it has been proved that the fine dust and fume are greatly reduced.

Company Reports

RHODE ISLAND COPPER COMPANY

This is one of the Dow Michigan companies, formed in 1898, with a capitalization of \$2,500,000. It is controlled by the Franklin Mining Co., which owns nearly all the shares. The property, 800 acres, adjoins the Franklin, Jr., and has been explored by diamond-drilling and underground work. The most promising ground is in depth, and exploration will hereafter be carried on from the deep levels of the Franklin. The treasurer's statement at December 31, 1912, shows that receipts from copper were \$42,928 and other revenue \$46,021, while cash on hand was \$14.25.

HOUGHTON COPPER COMPANY

This Company, organized in 1910, is controlled by the St. Mary's Mineral Land Co., from which it bought the mineral rights to 160 acres lying between the Isle Royale and the Section 16 mine in Michigan. Out of 100,000 shares of \$25 each, 67,000 have been issued, \$5 paid, of which the St. Mary's company holds 37,228. The ground was explored by diamond-drilling and two copper-bearing beds found. The lode has been determined to correspond with the Superior, but where explored has so far proved rather irregular in copper content. A shaft has been sunk 623 ft., and a winze extends 200 ft. deeper, the best ore having been found in this winze. The general manager, L. L. Hubbard, has recommended sinking the shaft.

CONSOLIDATED GOLD FIELDS OF NEW ZEALAND, LIMITED

The Company was registered in 1896 to adopt an agreement made with David Ziman for the purchase of properties on the west coast of New Zealand. The property consists of the Wealth of Nations, Blackwater, and Progress mines. The capital is £300,000, in 299,999 ordinary shares of £1 each, and one founder's share of £1; 242,377 ordinary shares and the one founder's share have been issued and are fully paid. The founder's share takes 25% of the profits after 100% has been paid on the original capital. The report for the year ended December 31, 1912, shows that 10,936 tons from the Wealth of Nations yielded bullion valued at, exclusive of concentrate, £17,432, or 31s. 10.56d. per ton. The working expenditure was £11,719, or 21s. 5.19d. per ton. In addition to the tonnage milled, 7325 tons of sand was treated in the cyanide plant, and 59.5 tons of concentrate was obtained from current work. The ore reserves are estimated at 34,000 tons of an average value of 11 dwt., together with an additional 10,000 tons of ore partly developed. The total costs for mining, milling, general expenses, and bullion charges amounted to 21s. 5.19d. The Company's interest in the Blackwater Mines, Ltd., remains at 93,224 shares. The holding in the Progress mines remains at 169,943 shares. The revenue of the Company was as follows: gold from the Wealth of Nations mine, including £467 from gold reserve, £17,899; dividends on investments, rent, interest, and sundry receipts in New Zealand, £1936; a total of £19,835. The expenditure in New Zealand and London on mining and milling and general administration expenses, including special expenditure during strike, amounted to £16,638, leaving a balance of £3197. As the ordinary shareholders received dividends amounting in the aggregate to 100%, the founder's share is now entitled to receive 25% of the annual profits available for distribution, or equal in amount to one-third of all future dividends declared, and a final payment of £2019 has already been made thereon.

THE PROGRESS MINES OF NEW ZEALAND, LIMITED

The Company was registered in 1896 to acquire from the Consolidated Gold Fields of New Zealand, Ltd., a gold mining property covering 733 acres on the west coast of South Island, New Zealand. A coal area of 48 acres has also been acquired. A 40-stamp mill has been working since 1898, and 25 stamps since March 1900, making 65 stamps and cyanide plant now at work. The capital is

£275,000, in 275,000 shares of £1 each; all the shares are issued and fully paid. The report for the year ended December 31, 1912, shows that 8770 tons of ore was milled. This yielded 2043 oz. of fine gold valued at £8650. The total ore cyanided was 9035 tons, yielding 754 oz. fine gold worth £3183. The whole product was worth £12,536. In addition, 92.82 tons of concentrate was produced, the estimated value after deducting returning charges being £1633. A loss of £2448 was made on the year's work, caused by the miners' strike.

THE BLACKWATER MINES, LIMITED

The Company was registered in 1906 to acquire from the Consolidated Gold Fields of New Zealand, Ltd., and the Progress Mines of New Zealand, Ltd., a gold-mining property at Blackwater, Reefton district, New Zealand. The capital is £250,000, in 250,000 shares of £1 each, all the shares being issued and fully paid. The report for the year ended December 12, 1912, gives the total ore mined as 12,847 tons, at a cost of 15s. 5.14d. per ton. Of this, 11,538 tons was milled. Following is a summary of the ore treated.

Owing to labor troubles, the working operations of the Company covered only a period of less than five months,

THE BLACKWATER, PROGRESS, AND WEALTH OF NATIONS PROPERTIES ARE AT REEFTON IN THE SOUTH ISLAND.

making a considerable increase in the cost per ton. One hundred thirty-two tons of concentrate was produced from current work, while 229.15 tons of accumulated concentrate was sold for a net return of £2170. The ore reserves are estimated at 71,905 tons, and, in addition, a further tonnage of 27,715 tons of only partly developed ore, making a total of 99,620 tons of an average value of 10.18 dwt. over 26 in. During the year, £28,750 was realized from gold, which with £141 for rent and sundry receipts in New Zealand makes a total gross revenue of £28,891. The total expenditure in New Zealand and London was £22,221, leaving a gross profit of £6670. Since the close of the Company's financial year, for the first six months of the current year 21,680 tons has been crushed, yielding gold to the value of £43,099, or equal to 39s. 9d. per ton, and showing a working profit of £20,559, or 18s. 11½d. per ton. This is sufficient to dis-

charge the outstanding liabilities at the end of the financial year, and, given normal conditions, it is anticipated that the payment of dividends will be resumed during the current half-year. The profit over revenue expenditure during 1912 was £7238.

BEAVER CONSOLIDATED MINES, LTD.

The report of this Cobalt company for the three months ended August 31 gives the following information:

Underground work, feet	1,083
Stoping, square yards	1,058
Operating profit	\$40,000
Cash on hand	26,098
Due from smelters, ore on hand, net.....	127,910

The main shaft is down 800 ft. and a station was cut at this level. On the 460-ft. level there is ore in both drifts and stopes. This shoot is 3 to 4 in. wide on the 530-ft. level, and further cross-cutting opened a 2-in. vein assaying 1950 oz. per ton. No. 5 vein is now opened from the 200 to the 700-ft. level. A new hoist of 1500-ft. capacity and a 6-ft. mill have been ordered for the mine and plant, respectively.

WINONA COPPER COMPANY

This Company was organized in 1898 and has the usual Lake Superior capitalization of \$2,500,000, in shares of \$25, of which \$11 has been paid in. The Company owns about 1600 acres and has timber rights over an equal area. There are four shafts on the Winona amygdaloid. During the year 181,148 tons of ore was milled, yielding 2,307,237 lb. of refined copper, or 12.74 lb. per ton. Experiments were made in regrinding the tailing in Hardinge mills. It was thus found that an additional recovery of 1.2 lb. copper per ton could be made. Three mills have been installed, and three more have been ordered, to be placed in tandem, it being thus hoped to save ½ lb. additional per ton. Development work in the mine is estimated to have opened a reserve of 240,000 tons of milling ore.

Expenditure during 1912 for mining, hoisting, rock-house, transportation, stamping, surface, office, and incidental, totaled \$406,264.85. Diamond-drilling cost \$239, and construction \$23,036.12. Assets total \$177,678 and liabilities \$115,644.

ALGOMAH MINING COMPANY

This is one of the Dow properties, and was launched in 1910 with a capital of \$2,500,000, of which \$1,750,000 has been paid in, \$1,500,000 in shares having been exchanged for the property, and 10,000 shares having been sold at \$10. The property, 480 acres, is just south of the Lake mine, in the Superior region. Some diamond-drilling was done. The No. 6 hole discovered three promising beds of amygdaloid, and sinking the shaft is being continued, as it is proceeding in the direction of the hole. The Company lost nearly \$29,000 by the failure of S. R. Dow & Co., and, with the other Dow companies, is now controlled by the United States Smelting, Refining & Mining Co. The statement of expenses at the mine for the year ended December 31, 1912, is as follows: mine work, \$32,284, and office and taxes, \$10,560.

The cost of diamond-drilling was \$3.13 per foot, driving and cross-cutting cost \$9.09 per foot. The assets of the Company are given as \$616,836 in real estate and improvements, general expense account \$165,463, and cash assets sufficient to bring the total to \$788,633.49.

PRINCE CONSOLIDATED MINING & SMELTING CO.

This Company operates near Ploche, Lincoln county, Nevada, and the report covers the past fiscal year. The manager, A. Y. Smith, stated on August 15 that underground work had covered 3775 ft. at a cost of \$5.90 per foot. The mine is in excellent condition, and extraction of ore can be conducted for a considerable time with little development. From an area of 1052 sq. ft. there was shipped 86,428 tons of ore, and there is 10,977 tons in the stopes, this making 10.8 cu. ft. of ore per ton in place. A 50-hp. hoist has been installed. The railroad from the mine to Ploche, 9.71 miles, gave satisfactory service. Diamond-drilling from No. 6

level has proved a large sulphide zone below water-level. The Company has a contract with the International Smelting & Refining Co. at Tooele, Utah, for daily ore shipments of from 150 to 250 tons. Trial lots were sent to the United States Smelting, Refining & Mining, and American Smelting & Refining companies' plants in Utah, but returns from the Tooele plant were the most satisfactory. To this plant was sent 39,544 tons of ore averaging silver, 2.66 oz.; lead, 3.01%; iron, 29.68%; lime, 6.41%; manganese, 11.07%; and insoluble, 13.46%. The net smelter return was \$2.63 per ton. From early milling operations at Bullionville and Dry Valley, about 12 and 6 miles from Pioche, respectively, 220,000 tons of tailing remained. Part of this was concentrated and 50,000 tons shipped to Salt Lake smelters. It is estimated that there is 100,000 tons of tailing available for local treatment at a net profit of about \$350,000. The net profit for the year from all sources was \$58,860, less \$25,394 depreciation.

OTAVI MINES & RAILWAY COMPANY

The Company was formed in Berlin, in 1900, in accordance with an arrangement with the South West Africa Co., Ltd., the Direction der Disconto Gesellschaft of Berlin, and the Exploration Co., Ltd., to develop the mineral and railway rights in the territory of the South West Africa Co., Ltd., and took over from that Company 1000 square miles of mining rights and 500 square miles of freehold land in the Otavi district of German Southwest Africa. A railway from Swakopmund, in the mining district of Tsumeb, was finished in August 1906, and in 1910 was sold to the German government for 22,000,000 marks. The Company has leased the line for ten years with the option to extend the lease for a further twenty years. The Tsumeb copper mine is being opened, and the Company has interests in the Otavi Exploring Syndicate, Ltd. The capital is 4,000,000 marks, divided into 200,000 fully paid shares of 20 marks, or \$4.80 each; all the shares are issued and fully paid. There are also 200,000 deferred shares of no face value. The report covering the period from April 1, 1912, to March 31, 1913, gives the amount of ore raised at 54,100 tons. Of this, Tsumeb accounted for 52,200 tons, that is, 11,200 tons in the open workings and 41,000 tons at depth. The cost price of the ore has been reduced to about 20 marks per ton. Extensive trials in Germany, made with a view to dressing by wet mechanical process the ore from the eruptive body, which had so far been left in the mine as worthless, have been entirely successful, even the results from the poorest part of the eruptive body were satisfactory. A dressing plant has been ordered to treat at the start a daily quantity of 50 tons of eruptive ore. The Otavi Valley mines gave 1900 tons. Shipments totaled 44,500 tons, with average contents of 13% copper, 25% lead, and 230 gm. silver per ton. The lower metal content of the ore, compared with the previous year, is explained by the shipment of the 8000 tons of low-grade ore which had been lying on the dump at Tsumeb. An occurrence of mottramite was discovered at Tsumeb-West, from which about 200 tons of copper and lead-bearing vanadium ore containing on an average about 10% vanadium oxide was mined and shipped. The Otavi Exploring Syndicate shipped a first lot of about 500 tons copper and lead ores from Asis-East, and about 35 tons high-grade tin ore from various tin properties. The smelter was at work for only 112 days, as the quality of the Tsumeb ores and favorable metal prices made it possible to export a larger proportion. The productions amounted to 655 tons of copper matte, with an average content of 48% copper, 25% lead, and 440 gm. silver per ton; and 400 tons metallic lead, with average contents of 98% lead and 910 gm. silver per ton. The smaller proportion of metallic lead to copper matte, compared with the previous year, is due to the fact that a larger part of the galena was sold at the favorable prices then ruling, and pyrite was used instead of the galena to supply the sulphur required in smelting. The net profit for the year was 3,820,310 marks, 36 pf. A dividend of 5%, equal to 1 mark per ordinary share, on 4,000,000 marks, amounted to 200,000 marks. Seven marks super-dividend per ordinary share amounted to 1,400,000 marks, and 7 marks per deferred share to 1,400,000.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

IN sampling cakes at the Waihi filter plant, the sample is taken from every basket and every other leaf of each basket throughout the 24 hours. The samples from each unit of the plant are reduced by cutting and the three bulked together, the final weight of sample being about 20 lb. This is wrapped in clean filter-cloth and squeezed between two vertical iron plates by screwing-up bolts. The solution squeezed out is caught and 20,000 gr. assayed by evaporation (over water bath) with litharge. The squeezed sample is then further reduced, thoroughly broken up in water by hand, washed by decantation, and assayed in triplicate, 1000 gr. being taken for each charge.

WOOD-STAVE PIPE of 4-ft. diam. and about one mile long is being constructed for a hydro-electric scheme in Tasmania. There will also be three-quarters of a mile of steel pipe. The source of the power, 40,000 hp., is the watershed of the Great Lake, which has an area of 210 square miles. Turbines will drive three-phase alternating generators, producing 6600 volts, which will be stepped up to 88,000 volts for transmission over 60 miles to Hobart over aluminum lines. The towers will be similar to those used in the United States. Power will be used for making calcium carbide and will be sold to numerous factories. The total cost of the plant will be nearly \$3,000,000.

LINDLEY's definition of mineral land may be stated as follows: "The mineral character of the land is established when it is shown to have upon or within it such a substance as is recognized as mineral, according to its chemical composition, by the standard authorities on the subject, or is classified as a mineral product in trade or commerce, or such a substance as possesses economic value for use in trade, manufacture, or ornamental arts, and it is demonstrated that such substance exists therein or thereon in such quantities as to render the land more valuable for the purpose of removing and marketing the substance, than for any other purpose, and the removing and marketing of which will yield a profit, or it is established that such substance exists in the land in such quantities as would justify a prudent man in expending labor and capital in the effort to obtain it."

PRECIPITATION of gold from cyanide solutions on zinc wafers, as devised by J. S. MacArthur and details published in the *Mining and Scientific Press* of March 15, 1913, has recently been tried at the Waihi mills, New Zealand, and the City & Suburban mill on the Rand. In the first instance, the trays in a zinc box of eight compartments were covered with three inches each with wafers. Solutions entering the box assayed gold 4 dwt. and silver 32 dwt. per ton, the strength being 0.023 to 0.07% KCN. The result of a number of tests, according to J. H. G. Banks, showed the extraction to be 50 and 65% of the gold and silver, respectively, against 95 and 99% by ordinary zinc-shaving precipitation. At the Rand property, according to E. G. Baskett, in the *Journal of the Chemical, Metallurgical, and Mining Society of South Africa*, four compartments of a zinc box were filled to a depth of 3½ in. with wafers, and three compartments filled with zinc shavings, the eighth cell, between the wafers and shaving, being left empty, but fitted with a sampling tap. The solutions assayed from 0.97 to 1.11 dwt. per ton and tested an average of 0.056% KCN. Extraction varied from 31 to 37%. White precipitate on the wafers hindered precipitation. The zinc shaving in the lower cells gave 94% extraction. Tests with stronger solutions gave an average of 32% recovery.

DUST from roasting, reverberatory, and blast-furnaces, and kilns at cement works, may be greatly reduced by means of the Cottrell electrical precipitation process. At

the Riverside Portland Cement Co.'s plant at Crestmore, California, this process is in successful operation, and the following notes were supplied the *Riverside Daily Press* by the Western Precipitation Co., of Los Angeles, which controls the patents. The work was begun in 1900, and although the final improvements have not been applied to the whole dust-catching plant, yet results recently obtained on part of the apparatus show remarkable efficiency. The dust-treating plant has now been in steady operation since January last, and from the splendid results obtained, it would seem as if the dust troubles of the Riverside Portland Cement Co. are practically over. For various reasons it was judged by the Company's engineers to be desirable to place the dust-treating apparatus on top of the existing stacks. Each kiln has a separate double treater, entirely independent from others, thus, should it become desirable for any reason to shut down one-half of any individual treater, the whole volume of gas and dust can be passed through the other half, or any kiln and its treater be shut down without affecting the rest of the treating system. Each half treater is rectangular in shape, 14 ft. high by 12 ft. wide by 35 ft. long. The treater boxes contain a system of discharge and collecting electrodes, between which flows a constant discharge of approximately

BUILDING FRAMEWORK FOR COTTRELL PRECIPITATING APPARATUS AT RIVERSIDE CEMENT WORKS.

60,000 volts of uni-directional electric current. To obtain this high voltage it is first necessary to step-up the alternating current entering the electrical apparatus at 220, to 60,000 volts, then, by means of a special rectifying machine, change this 60,000 volts of alternating current to 60,000 volts of direct current. All the high-tension wires are enclosed in screen cages, and it might here be mentioned that there never has been an accident of any kind due to careless handling of this high-tension current. The dust-laden gases enter the Cottrell treater without previous cooling, at about 825°F. and at nearly 4000 ft. per minute velocity. This means that it takes about three seconds for a unit of gas to pass through a treater, and during this three seconds the dust is precipitated by electrical means and left behind, the gases escaping through an outlet stack free from all solid particles. Once each hour the treaters are cleaned by mechanical devices, the collected dust, falling into hoppers, being weighed on automatic scales and conveyed to bins, where it is available for shipment as fertilizer or other uses. The only color showing at the outlet stacks is that of the smoke from the burning oil and minute quantities of potash, which leave the stacks as gases, condensing after they meet the colder outside air. This potash, largely soluble in water, is of the same chemical composition as the high-priced fertilizing potash purchased by all orange growers. Measurements show that each kiln stack delivers to its corresponding treater over 5,000,000 cu. ft. of gas per hour, carrying about 700 lb. of dust, or a total of over 90 tons of dust per 24 hours for the whole plant. The 90 tons of dust sold as fertilizer or asphalt filler brings in a revenue more than sufficient to pay for the entire operating costs of the Cottrell treaters, including electrical energy, labor, depreciation, and interest on the investment.

Machinery Trade in Switzerland

The total exports of Swiss machinery in 1912 amounted to \$17,773,341, and in the preceding year were only \$16,092,557, showing that 1912 was a prosperous period for the machine manufacturers. The industry is centred in the Zurich district, and there are several large and well known concerns, such as Sulzer Bros. and the Swiss Locomotive Works, at Winterthur; Escher, Wyss & Co., of Zurich; Brown, Boveri & Co., of Baden; and the Oerlikon Machine Works, at Oerlikon-Zurich. The first-named company manufactures Diesel oil-engines, the second makes all of the locomotives used on the Swiss state railways. Escher, Wyss & Co., and Brown-Boveri are important manufacturers of large turbines of various kinds and machinery for hydro-electric plants. All of these firms report a favorable business year during 1912, and the Oerlikon firm especially has been benefited by the movement toward the complete electrification of the federal railways. They are manufacturers of electric locomotives, and during the past year have constructed those for use on the new Loetschberg-Simplon route to Italy, upon which electric traction will be employed. These locomotives weigh 112 tons complete, and contain two motors of 3000 hp., weighing 27 tons each. The cost of construction is about twice that of an ordinary steam-engine, being about \$40,500.

The principal machinery exports from this district are electric dynamos, gas and oil engines, milling machinery, hydraulic machinery, and steam-engines. It is estimated that nearly three-fourths of the total exports of machinery from Switzerland come from this district. Exports of machines and parts thereof from Zurich to the United States in 1912 were valued at \$91,978, as compared with \$54,052 in 1911. Included in this amount were several shipments of adding and calculating machines and of ball-bearings, the trade in which seems to be increasing.—*Daily Consular Report*.

QUESTION as to the relative merits of the 'Giants' and 'Athletics' has for the time being taken precedence over the less important Mexican and Japanese problems, currency reform, income tax, and other minor subjects of debate.

NOW that the new tariff schedule has gone into effect and the high-cost-of-living question relegated to the past, we can only hope that the contemplated currency reform will make two dollars appear where there was formerly but one. However, as the proof of the pudding is in the eating, bank books, when balanced a year from now will be the real criterion whereby the wisdom of our reformers may be judged.

RECENT concessions granted by governments of Colombia and Ecuador to S. Pearson & Son for the privilege of prospecting for oil throughout these countries, marks the establishment of another important enterprise in Latin America. While the project is speculative in nature, oil has been produced in Ecuador, and the history of Lord Cowdray's Mexican enterprises permits an optimistic attitude toward this, the latest of his ventures. A field force is already at work in Colombia, we understand, under the capable direction of Mr. A. C. Veatch.

NOME, the sturdy little city of the Far North that has contributed so much to the world's stock of gold, suffered a most severe disaster in the great storm that swept the beach last Sunday. Details are few as yet, but such as are available are given in our news pages. While the city itself lost much, and prompt action is necessary to prevent hardship due to destruction of food supplies, but two dredges, the Roberts and the Sionx-Alaska, are reported seriously injured. Mining on the beach itself is no longer important, as the hydraulic mines and most of the dredges are back some miles from the shore. Our sympathy goes out to the men of the North, but they are of too plucky stock to be more than temporarily discouraged even by the fiercest of storms.

COMPLETE presentation of the oil resources of California in a single volume is promised by work just undertaken by the State Mining Bureau, Mr. F. McN. Hamilton, the state mineralogist, having arranged for Mr. R. P. McLaughlin to devote a year to the task. The geology of the individual fields has been elaborately studied by the United States Geological Survey, and technical features of oil production in the state have been described by the Bureau

of Mines and numerous writers in *Western Engineering*, and other technical journals. We present this week an admirable though brief review of present production, written by Mr. J. H. G. Wolf, and it is a type of the excellent papers written by many engineers connected with the oil industry. There is, however, a real need for a general summary volume, and Mr. Hamilton is to be congratulated on taking such effective means to meet this need.

AT this time of the year the movement of gold is away from the great financial centres, and some uneasiness is expressed by the hoarding tendency of India and the present status of gold in Brazil and Egypt. The shipments of gold to Egypt, in view of the present price of cotton, will approximate £10,000,000, according to advices from London. From Brazil there is reported a shortage in note currency due to the export of sovereigns. The new Minister of Finance is said to be determined to sell the Dreadnaught, which is being constructed in England, in order to direct the exportation of gold to Brazil. The Indian financial question is considered by some British bankers as the most pressing of their problems, and the enormous drain of gold in that direction is one of the worries of the bankers of the world. A royal commission was appointed some time ago to inquire *inter alia* into complaints from the Indian business community that under the present system the government is taxing India unnecessary to keep large balances in London. The committee reports that the balances are no larger than needed to meet the payments on revenue and capital account. The commission urges that the gold standard reserve be kept where it would be needed if the exchange were in jeopardy, that is in London. It is also proposed to establish a state or central bank to act as banker for the government balances in India, manage the paper currency, and participate in the sale of drafts on India for meeting the government requirements in London. The consensus of opinion is against any organized effort to force a gold currency on India, by the free coinage of gold at an Indian mint or otherwise, as it is believed that such a coinage would be absorbed in jewelry and hoards, and enough is flowing into these channels at the present time.

REVISION of the mining law is proposed on many sides and serious work toward shaping that revision is under way. From the first meeting of the American Mining Congress the resolutions committee has always had before it a number of definite complaints and of proposals for revision. Eventually a special committee was appointed to consider the subject, and of this, Mr. E. B. Kirby is the active and efficient chairman. In a report made in 1911, and printed in the *Mining and Scientific Press* on October 28 of that year, a number of the points in the United States mining law that required change were listed and a demand for a general consideration of the subject by a commission or otherwise as Congress might elect, was presented. The next national organization to take up the matter was the Mining and Metallurgical Society, and we print this

week the report of a committee, consisting of Messrs. H. V. Winchell, C. W. Goodale, and M. L. Requa, which has studied the subject for nearly two years. It will be noted that this committee also concludes that the time has come for a thorough re-study of the law and has reached definite conclusions as to certain points that need change. This report is now before the members of the Society for vote, and we purpose at another time to discuss in detail certain of the particular recommendations. A third organization, the American Institute of Mining Engineers, has just taken steps looking toward joining in this movement, in that a committee on mining law has been appointed, with Mr. H. V. Winchell as chairman, Mr. John W. Finch secretary, and an excellent and authoritative membership. We understand that it is proposed to devote the February meeting of the Institute to discussion of questions raised by this committee. We are firm believers in the need of many changes in the mining law. Just how many and what they should be are proper subjects for differences of opinion, and we shall be glad to hear from our readers, especially those who disagree with the conclusions of the committees. We would not arrogate to ourselves all wisdom, and it is just as well that at times the voice of the standpatter should be heard in the land.

Educating the Public Regarding Mining

Horse shows, automobile shows, electrical shows, cement shows, all these have come to be annual features of the life of many of our great cities. The county fair, devoted at least ostensibly to development of agriculture, is the great yearly event at thousands of county seats, and the larger and grander state fair each autumn brings crowds of the curious to capitals. Nearly every business pursued in the United States is annually brought to public attention through exhibitions of some sort—nearly every business save the ancient and honorable pursuit of mining. That alone of the important industries of the country has neither a great permanent, nor an established annual, exposition devoted to informing its followers of improvements in the art, and to educating the public to the importance of the industry. So accustomed is the public to this state of affairs that few have noted the absence of mining exhibitions. In years gone by Ottumwa in Iowa supported a 'coal palace,' and it served a useful purpose in that it taught the farmers of that great state that mineral, as well as agricultural, wealth forms a basis for the prosperity of a community. In other cities spasmodic attempts have been made to attract public attention to mining, and in the public and school museums there may usually be found by a persistent visitor, hidden behind geographic models, cases of natural history specimens, the usual wealth of old armor, and the inevitable spinning wheel of our foremothers, a dusty and often inaccurate model of a mine or mill. This is hardly the way to educate the great general public to a sense of the importance and dignity of one of the basic industries of civilization, and it is not surprising that mining suffers greatly from public ignorance and misapprehension. In a country of varied industries and popular law-

making, each individual business must work under laws framed by people a majority of whom are ignorant of it. A mining man is so rarely a member of any legislative body that such a one is apt to be pointed out to visitors as one of the curiosities of the chamber, and he is always hopelessly in the minority. It is not surprising that there is loud complaint of discrimination against mining by taxing bodies, though it is anomalous that in Colorado, the home of so many mines, the legislature should pass a law providing for assessment of mining property at its full cash value, plus one-half the gross output, plus all the net for the previous year! Such a basis of taxation applied to farms would produce a revolution.

Laws equally discriminatory have been enacted and are now enforced against mining in other states, and the mining men are largely to blame. They have been persistent in the excellent matter of attending to their own business, but have done this too narrowly. They have forgotten that in a democracy no industry can prosper unless there is a healthy and informed public opinion regarding it. Up to the present the fake promoter, the peddler of ten-cent shares based upon a hole in the ground and a whole lot of regardless optimism, has been the only one willing to spend money even to misinform the public about mining. It is because of this that mines are foolishly regulated, inequitably taxed, and "nobody can raise money for a prospect without lying about it." Is it not time to call a halt?

One of the best features of the work the American Mining Congress has done, and it has several to its credit, is the persistent effort that it makes to give the general public correct ideas about mining. In conducting this work the officers of the Congress have this year brought into service a new agency, in that provision has been made for a mining show at Horticultural Hall, Philadelphia, in connection with the annual meeting of the Congress, October 17 to 25. We understand that the available space was promptly taken and that an excellent exhibition is assured. No doubt there will be many things to be seen that will be of interest and value to mining men themselves; the more so since from the situation the exhibits are likely to be especially strong in all that relates to coal mining, and Western metal miners have much to learn from their associates in the East who work at the prosaic but necessary task of digging the coal that forms 'the mainspring of civilization.' If, however, there was nothing shown that was of direct benefit to the mining men, such an exhibition would be distinctly worth while. It will be seen by thousands who have never had any independent means of forming a correct estimate of mining, and these thousands none the less, in one way or another, exert an influence upon the conditions under which mining must be conducted. Supplemented as this exhibition will be by the presence of hundreds of mining men, and by the active discussions of the Congress itself, the total influence toward sound thinking in mining matters is bound to be important. Mining men should get away from thinking of exhibits, whether at such an exposition as this or at the Panama-Pacific, as merely oppor-

tunities for manufacturers to show goods; they must not measure the value to them of such organizations as the Mining Congress by the papers they read and the ideas they receive. They must learn to look upon these agencies as means of educating the public. If the general public realized the actual conditions under which bituminous coal mining is now conducted, the laws would be promptly changed; if the fact that mining involves liquidation of capital was properly appreciated, tax laws would be better framed; if there were a more general ability to measure the risks and rewards of mining, there would be less money foolishly wasted and dishonestly appropriated, and more capital for legitimate development. The key to all this is education of the public, and in this great work the American Mining Congress is playing an honorable part.

The Rand Banket

By T. A. RICKARD.

With this issue we begin the publication of a series of articles, constituting a comprehensive treatise, on the great ore deposits of the Witwatersrand, in South Africa. The author is Mr. C. B. Horwood, an Associate of the Royal School of Mines and a graduate in science from the University of London. In addition to his scientific training, Mr. Horwood brings to his task the essential qualifications of observation and experience underground in the mines that now contribute 40% of the world's annual production of gold. He has served his apprenticeship as assayer, sampler, surveyor, shift-boss, and underground superintendent, passing finally from these minor posts to that of general manager of a large property. His last appointment on the Rand was as joint manager of the Randfontein Central group of mines. Thus he is fully qualified for the work he has taken in hand. Indeed, it is our opinion that to such men, familiar alike with the tenets of science and the teachings of observation, we must look for illumination upon the many problems that obscure the genesis of ore deposits. Deduction from principles must be checked by induction from facts. Spencer said that Huxley's idea of a tragedy was a beautiful theory killed by an ugly fact. Many are the tragedies so enacted since the conglomerate lodes of the Rand came into prominence. Nor has the scientific drama lacked such touches of comedy as are inherent in the human approach to Nature's secrets. Before the curtain is lowered we may hope to see and hear further duels between brutal facts and iridescent theories, for we expect that Mr. Horwood's latest contribution to a fascinating subject will be followed by a discussion on the part of the many authoritative writers whom he quotes so conscientiously. Among these are Messrs. George F. Becker, J. S. Curtis, E. T. Mellor, A. R. Sawyer, L. De Launay, J. W. Gregory, F. H. Hatch, George J. Corstorphine, R. B. Young, S. J. Truscott, and H. F. Marriott. In making reference to lateral questions arising from the immediate subject, Mr. Horwood quotes from writings familiar to our readers, particularly those of Messrs. James F. Kemp, Waldemar Lindgren, Franz Posepny, Malcolm MacLaren, C. R. Van Hise, S. F. Emmons,

J. H. L. Vogt, R. W. Raymond, R. K. Dunean, and F. W. Clarke. In other words, this study of the 'banket' has been undertaken in a scholarly manner. Incidentally, Mr. Horwood refers frequently to his own previous writings, which, in effect, are summarized and brought up to date by this, his latest and most finished, contribution.

By way of introduction to Mr. Horwood's treatise, we may be permitted to give a brief outline of the general geologic conditions on the Rand, as we have inferred them from the literature of the subject. The White Waters Range or Witwatersrand is a low ridge marking the northern edge of a big syncline, the major axis of which runs east and west. Sedimentary rocks, consisting of quartzite, conglomerate, and shale, are found dipping southward, at first steeply near the surface and then flatly as depth is attained. These constitute the Witwatersrand system, the age of which is pre-Cambrian or Algonkian. It is overlain by patches of coal measures and by dolomite. Among the beds of the Witwatersrand system are several composed of conglomerate in which gold exists in such proportion as to make the rock economically valuable. The chief group of gold-bearing conglomerate is called the Main Reef series. Whatever the origin of the gold, that of the conglomerate or 'banket' in which it now lies is not open to dispute. It is part of a marine deposit accumulated along a subsiding shore modified by east and west currents. The quartzites exhibit ripple markings, indicating periods of shallow water. The pebbles of the conglomerate vary in size from a plover's to a goose's egg; they consist mainly of quartz; but they also represent rounded fragments of the rocks from which that quartz was derived. It would appear that the ancient land, of which these consolidated sediments represent the wreckage, was crossed by numerous veins of quartz and by porphyritic granite rich in quartz. The pebbles are imbedded in a matrix composed mainly of sand cemented by pyrite and secondary silica. The gold lies chiefly in the matrix, and is closely associated with the pyrite. More cannot be said without trespassing on debatable ground. It remains only to add that by the subsequent elevation of these sedimentary deposits and the later bending of the strata, they were upturned. This plication, ending in the formation of a big syncline, is connected with the intrusion of diabase and other geologic changes of a profound character. In the end the upturned edges of the conglomerate were found outcropping at a steep angle, and by mine openings it was ascertained that the dip flattened gradually to 20° at a depth of from 3000 to 4000 feet. This flexure was accompanied by fracturing, now expressed by faults, and was followed by the injection of igneous matter, now appearing as dikes of diabase. Thus far we may go without protest from either side in the great debate that has ensued concerning the origin of the gold in the conglomerate. We now return to Mr. Horwood's presentation of the case.

In his first article, Mr. Horwood states the purpose of his writing. He furnishes a concise description of the general structural conditions modifying the local geology of the Rand. In doing so, he indicates

his line of approach to the investigation, which immediately takes him to the lode theory of the deposits as against the placer idea. In one of his earliest paragraphs we find mention of the shale beds that limit the diffusion of the gold in the conglomerate series. A preliminary reference to the dikes, illustrated by a beautiful photograph, will prepare the reader for the implied participation of thermal activity in the precipitation of the gold within the interstices of a porous rock. The concomitant faulting, also clearly illustrated, further opens the eyes of the student to an appreciation of the structural complications involved, and prepares him for a logical line of argument such as has served elsewhere to explain the formation of orebodies. Then comes the key to the whole problem, as viewed by our author. In the nodules of pyrite he finds his clue. These so-called pebbles of pyrite have caught the eyes and excited the scientific imagination of successive observers. Messrs. Becker and De Launay considered them to be water-worn fragments or real pebbles. Later observers, such as Mr. Ernest Schwarz, Professor R. B. Young, and Mr. Horwood himself have combated this view successfully. In the present paper, our author gives abundant evidence in support of his case, namely, that these 'pebbles' are metasomatic concretions and replacements. In his second article he quotes examples studied by him in great detail, both underground and with the microscope, from the Crown Reef, Rietfontein, and Randfontein mines. Many fine photographs are included in his evidence. Of these the pyritic pellets of the Buckshot Reef are the most remarkable. They show how the original matrix of the 'banket' has been replaced, not always completely, by the pyrite, films of which also have been detected lining minute cracks that pass through both the matrix and the pebbles of the conglomerate. Another point, vital in economic geology, is illustrated, namely, the observed tendency of the gold to be concentrated with these pyritic nodules. Indeed, the association of gold with iron sulphide is a far-reaching observation, for it prepares the way for the further evidence, in the third article of this series, indicating that thermal activity came in the wake of such eruptive action as is represented by the diabase dikes, especially those that have intruded along the strike of the sedimentary strata. The circulation of mineral solutions, thus stimulated, has been modified by structural conditions typified by the shale, which, by confining the precipitation of the gold within recognizable limits, has induced a concentration that resulted in the formation of orebodies having great economic value. This thesis is further elaborated and confirmed in the succeeding articles, on which we defer comment. Enough has been said to suggest the great interest of this latest presentation of the banket problem. We hope that the usefulness of it may be further enhanced by discussion involving criticism both penetrating and polite, such criticism as evolves light rather than heat; light to illumine those dark places underground where the miner seeks with unwearied persistence not only for gold and silver but for the more precious knowledge that shall aid the generations yet to come in their search for the metallic implements of our material civilization.

The Rand Banket and Its Gold Content—I

By C. B. HORWOOD

Introduction

The object of this paper is first of all to describe the mode of occurrence and origin of the pyritic replacements found in the gold-bearing conglomerates or 'bankets' of the Witwatersrand, in the Transvaal province of the Union of South Africa. For the benefit of those unacquainted with the Rand, a brief account is given of these conglomerates and the formation in which they occur. The most remarkable of the replacements are the so-called 'pebbles' of pyrite; and it is therefore with these that the first part of this paper chiefly deals. This necessarily involves a study of the structure of the 'pebbles',¹ and of the whole subject of replacement, or metasomatism, which recently has been so ably elucidated by Waldemar Lindgren.² Incidentally, it becomes necessary to enter somewhat fully into the question of concretions, and also that of the shape of these 'pebbles.' Then, the consideration of their origin introduces other subjects, such as the retaining influence of underlying shales and the close association between the occurrence of the pyrite 'pebbles' and high gold contents. These again lead us to consider the distribution of the gold, and, as they also have an important bearing on the genesis of the pyrite and gold in the banket, this final phase of the subject is somewhat fully discussed.

Occurrence and Description of the Auriferous Conglomerate.

The auriferous conglomerates, or 'reefs',³ of the Rand occur in the Witwatersrand system, which covers an area of over 1600 square miles in the southern Transvaal, and is also developed to a small extent in certain parts in the north of the Orange Free State. This system is underlain, unconformably, by the Swaziland system and by the Basement, or Old Grey, granite of South and Central Africa. Above, and separated from it by another 'unconformity,' are the volcanic rocks of the Ventersdorp system. The accompanying section, Fig. 1, from the Magaliesberg hills through Johannesburg and the ancient synclinal valley of the Witwatersrand and

continued through the Nigel district, illustrates the succession of the strata from the Old Granite upward through the Witwatersrand and Ventersdorp systems and then through the Black Reef, Dolorite, and Pretoria series of the Potchefstroom system.

Witwatersrand Rocks

The Witwatersrand rocks are composed of sediments fully 20,000 ft. thick, consisting of metamorphic and highly indurated quartzites and slates in which diabase intrusions and occasional beds of conglomerate occur. Owing to the absence of fossils and to want of correlation with European or other rocks of known age, it is impossible to fix the exact geological period during which they were laid down, but they are certainly of far greater antiquity than the Devonian period.⁴ The underlying granite is Archean, and the Swaziland system is almost certainly the same.⁵

The scenic aspect of the system is diversified by alternations of low hills and valleys, with few trees, little water, and scanty vegetation. The quartzites form the hills, which are characterized by steep escarpments and well defined dip-slopes. The valleys have been eroded in the slates and diabases, and, of these, the diabase valleys are the more fertile, owing to their greater richness in alkalis and alkaline earths. Where the dip of the beds is steep,⁶ as on the Rand, the vegetation is adversely affected.⁷

For the sake of convenience, the Witwatersrand system is divided into an Upper and a Lower division. There is no unconformity between them; the division, which is purely arbitrary, is placed at the base of the Main Reef series.⁸ The Lower division covers an area of about 970 square miles in the southern Transvaal. It is characterized by frequent alternations of quartzites and slates with comparative freedom from conglomerates, and has a total

⁴Hatch and Corstorphine, 'The Geology of South Africa' (2nd Ed.), Macmillan & Co. (1909), pp. 343-344.

⁵C. B. Horwood and A. Wade, 'The Old Granites of the Transvaal and South and Central Africa,' *Geol. Mag.*, Decade V, Vol. VI (Oct.-Dec. 1909), pp. 548-549.

⁶The dip varies according to the locality from about 30 to 80°. Along the Central Rand it varies from about 50 to 80 degrees.

⁷I have particularly noticed a pronounced instance of a similar effect at Rio Tinto, in southern Spain. There Paleozoic schist and slate, pierced by igneous intrusions, cover wide tracts of country. The slate and schist are either vertical or dip at a steep angle, and little vegetation will flourish on their upturned edges.

⁸E. T. Mellor has suggested that the division should be put about 125 to 400 ft. lower, so as to include certain coarse quartzites of varying thicknesses, locally known as the Red Bar, since the latter are of the same character, and form an integral part of the big succession of quartzitic rocks to which the Main Reef series belongs. 'The Normal Section of the Lower Witwatersrand System on the Central Rand, etc.,' by E. T. Mellor, *Trans. Geol. Soc. So. Af.*, Vol. XIV (1911), p. 110.

¹Throughout this paper when the term 'pebble', in single inverted commas, is used, it refers to one of the rounded masses of pyrite occurring in the auriferous conglomerates of the Witwatersrand which were formerly thought to be water-worn pebbles of pyrite.

²'The Nature of Replacement,' *Economic Geology*, Vol. VII, No. 6 (1912), pp. 521-535.

³Owing to the conglomerate beds of the Witwatersrand having been prospected and mined for gold, the term 'reefs' was applied to them by the early prospectors; and this Australian term has been retained and is now in general use. It is used as a synonym for vein or lode. It has no special significance as regards shape or appearance. It is really a nautical term. T. A. Rickard informed the writer that it was applied to veins or lodes by sailors who deserted from their ships to go to the early Australian diggings.

FIG. 1. SECTION FROM THE MAGALIESBERG THROUGH JOHANNESBURG AND THE NIGEL, ILLUSTRATING THE SUCCESSION OF THE WITWATERSRAND FORMATIONS AND ASSOCIATED BEDS.
(From Hatch's Geological Map of Southern Transvaal, 2nd Ed., 1903.)

thickness of some 10,000 to 12,000 ft. The three⁹ chief series of conglomerate beds in it are, from below upward, the Promise, the Coronation, and the Government reefs.¹⁰ Of these, the only one that is well developed and persistent for long distances is the Government Reef series; and this compares poorly with the principal members of the Upper division. This division has a thickness of rather over 10,000 ft.; it is characterized by being remarkably free from slates and by containing numerous persistent and well defined conglomerates,¹¹ which are divided from below upward into five main groups or series, known as the Main Reef, Livingstone, Bird, Kimberley, and Elsberg series. Of these, the Main Reef, Kimberley, and Elsberg are the largest and most important, and each contains several beds of conglomerate.

The Main Reef Series

Of these, the one selected in lieu of fissures,¹² by the gold-bearing mineralizing solutions for circulation and deposition of their mineral contents, was the Main Reef series. This series is divided into two sub-series, which are separated from one another by some 40 ft., to as much as 200 ft., of quartzites. The lower is known as the Main Reef series proper and comprises the Main Reef Leader¹³ and the Main Reef. The former varies in thickness from 3 to 4 inches up to 24 in. and occasionally much more in thickness. Frequently below this there is a fine-grained persistent band of shale, some 3 to 8 in. or more thick, by which it is either separated directly from the Main Reef; or below this again there may also be varying thicknesses of quartzite (up to as much as about 6 ft.) separating it from the Main Reef. The latter varies from about 4 to 5 in. up to 3 ft. on the Far East Rand to as much as 12 ft. in places along the Central Rand. The upper sub-series is known as the South Reef series. As typically developed along the Central Rand, it consists of three bands of conglomerate, varying in thicknesses and distances apart. Their occurrence in the western portion of the Consolidated Langlaagte mines, about 5 miles west of Johannesburg, may be taken as representative. There the upper or hanging wall banket is from about 9 to 18 in. thick and is separated by some

⁹The Du Preez series, which is auriferous and is profitably worked at the New Rietfontein mines, about 9 miles east of Johannesburg and about 4 miles north of Germiston, has not been included because it is still an unsettled question whether it belongs to the Lower Witwatersrand beds or whether it occurs as a faulted portion of the Upper beds.

¹⁰For the best description of these reefs, see E. T. Mellor, *loc. cit.*

¹¹Other very noticeable differences between the Lower and Upper Witwatersrand beds are that the slates of the former are generally ferruginous and the quartzites are frequently chloritic, more compact, crystalline, and contain less sericite. The quartzites of the latter contain much sericite and a little talc, and, speaking generally, are less compact and less crystalline than those of the Lower beds.

¹²For reasons to be explained later.

¹³The term 'leader' is applied to a bed of conglomerate, that as usually developed is of small thickness, or relatively so compared to the other conglomerate beds in the same series.

FIG. 2. A MAIN REEF LEADER STOPE IN THE ROBINSON MINE.

FIG. 3. THE SOUTH REEF IN A STOPE IN THE ROBINSON MINE.

8 to 12 in. of quartzite from the Middle Reef, which is usually about 3 to 5 in. thick. This again is separated by 8 to 12 in. of quartzite from the underlying South Reef Leader. The latter varies from a mere streak,¹⁴ or a single-pebble layer 1 to 1½

¹⁴Which is often only traceable by the differences in color and texture of the foot and hanging wall quartzites. In this mine, as is usually the case elsewhere, the South Reef Leader occurs in a dense, hard, black crystalline quartzite, and there is usually a sharp well defined line of demarcation between this quartzite and the light gray, or white, comparatively soft foot-wall quartzite on which it rests.

in. thick, up to a band of conglomerate 5 or 6 in. or more.

The face of a Main Reef Leader stope in the Robinson mine, at Johannesburg, is illustrated in Fig. 2. It shows machine 'boys' drilling holes for blasting, and the conglomerate beds in the quartzite can be distinctly seen. Fig. 3 shows a face of a South Reef stope in the same mine, and gives a good section of two banket layers separated by a parting of quartzite; and it also shows the quartzite above and below them. A good example of faulting and of a small dike, in the Nourse Deep mine near Johannes-

burg, is seen in Fig. 4.¹⁵ On the left-hand side of the figure the banket is faulted upward, the amount of displacement being equal in thickness to about one-half the width of the banket. Just to the right of the centre, a dike is seen, which has faulted the reef up on the right-hand side for a distance of about twice as much as in the previous case.

The Conglomerates

These conglomerates consist mainly of well rounded spherical, or ellipsoidal, quartz pebbles,¹⁶ light gray, bluish gray, and smoky colored, with occasional black ones. They usually vary in size up to 1 or 1½ inches in greatest diameter, though occasionally much larger ones occur.¹⁷ Few, and rather smaller, indurated dark-gray or black quartzite pebbles of similar shape are also present, and occasional black, or dark striped, angular, cherty-looking pebbles composed of hard slaty quartzite, varying up to about 1½ or 2 inches in greatest length. Small well rounded quartz pebbles up to about ¼ in. diameter, of a light sky-blue color are sometimes found. Speaking generally, they may be said to vary in size from that of a pea to that of a hen's egg; the average dimensions being, probably, about those of small walnuts.¹⁷ These pebbles are embedded in a fine-grained quartzitic matrix containing sericite, tale, chlorite, and some chloritoid.¹⁸ It is in this matrix that the gold of the banket is found. This gold is not pure; it contains some 10% of silver.¹⁹ Usually it occurs in minute hackly crystalline parti-

¹⁵These three photographs were taken by R. Neilson, of Johannesburg, who kindly gave permission to reproduce them.

¹⁶The quartz pebbles may have been derived to some extent from quartz veins in the older Swaziland system and in the Basement granite, but probably owe their origin for the most part to the granite itself, including its numerous pegmatite veins. See 'The Witwatersrand and Associated Beds,' by C. B. Horwood, Esson and Perkins, Johannesburg (1905), p. 47. See, also, C. B. Horwood and A. Wade, *loc. cit.*, p. 549.

For a fuller description of these pebbles see 'The Pebbles of the Rand Banket,' by R. B. Young, *Trans. Geol. Soc. So. Af.*, v. XV (1912), pp. 1-87.

¹⁹The average fineness of Rand gold may be taken as being 875 parts of gold per thousand, the rest being practically all silver. 'The Mode of Occurrence and Genesis of the Carbon in the Rand Bankets,' by C. B. Horwood, *Trans. Geol. Soc. So. Af.*, Vol. XIII (1910), p. 82.

cles, which are seldom visible, and it is intimately associated with, and often mechanically bound up in, iron pyrite, which forms 2 to 3% by weight of the banket.²⁰ The way in which the pyrite occurs in the banket has been so frequently described that it is not necessary to repeat in detail here. Speaking generally, it may be said to be finely disseminated in small crystals and rounded grains throughout the banket. The chief gangue is secondary quartz, which finally sealed these conglomerates against the further passage of mineralizing solutions.

The group of strata comprising the Witwatersrand system has usually been regarded as the result of deposition along a shore-line. However, E. T. Mellor,²¹ who has made a close study of these beds, thinks that the Lower division and the conglomerate of the Main Reef series were laid down under estuarine, or more probably deltaic, conditions on a large scale, alternating with comparatively deep-water conditions. He maintains that the evidence points to an interrupted, but on the whole progressive, cycle of changes from the moderately deep-water conditions of the lowest portions of the system through deltaic phases, resulting in the conglomerates of its middle portions, to the actual shore conditions exhibited by the uppermost beds, including the Elsburg conglomerates. De Launay²² had previously called attention to the great extent of these deposits, the relative regularity of the beds, and the frequent presence of flattened pebbles; and he expressed the opinion that they are marine rather than lacustrine deposits; but, since coastal deposits of shingle rarely have more than a small width transversely to the shore, they rather suggested a vast fluvial formation, or torrential deltas spread along an alluvial plain like that of Lombardy. He further concluded that they originally occupied a nearly horizontal position and owe their present dip to subsequent compression which brought about a great northeast-southwest syncline.

Typical Shore-Line Deposit

This system has its best known and probably most typical development on, and immediately to the south of, the Witwatersrand,²³ which is a low range of hills stretching from the town of Boksburg on the East Rand to Krugersdorp on the West Rand, a distance of over 30 miles. This range forms the divide between the watersheds of the Limpopo on the north and the Vaal river on the south. The former flows into the Indian Ocean and the latter into the Orange river, which discharges into the Atlantic. These hills, their southern slopes, and the ground immediately to the south, together with the areas where the Main Reef series is being worked beyond their eastern and western limits, constitute what is now known as the Rand, famed as the biggest goldfield the world has ever known. It is situated about 35 miles south of Pretoria.

²²'Observations on the Rand Conglomerate,' by L. De Launay, *Eng. and Min. Jour.*, April 4, 1903, p. 519.

²³Witwatersrand is the Dutch name; it means 'White waters range.'

about 390 miles due west of Delagoa Bay, about 470 miles northwest from the port of Durban, and about 1040 miles northeast of Cape Town. In altitude it varies from about 5400 to about 6000 ft. above sea-level. The climate resembles that of Arizona. Snow rarely falls, and the rainy season is from about November to April.

Structure of the Witwatersrand

The Witwatersrand, together with the extension of the system for some 16 miles eastward beyond Boksburg, forms the northern rim²⁴ of what is usually considered a great synclinal basin, the longer axis of which trends northeast.²⁵ On the Far West

beds, which, in consequence of the weight of the enormous superimposed masses of volcanic rock and the removal of them from below, sank, dipping inward toward the region whence the material had been withdrawn. Thus the dip everywhere is toward what is now the main axis of this synclinal valley. This axis naturally marks the line along which the main fracturing and resultant vents occurred. This intrusive activity would have also produced numerous lateral fractures up which igneous matter would have been forced, represented today by the big dikes, roughly parallel to the strike of the banket beds, which are encountered in the mines and occur here and there throughout the Wit-

FIG. 4. FAULT AND DIKE CROSSING A LOPE OF GOLD-BEARING CONGLOMERATE IN THE NOURSE DEEP MINES.

Rand this rim bends south between Krugersdorp and Randfontein. On the Far East Rand it sweeps southward a few miles east of the township of Springs, and then trends southwest past the town of Heidelberg to form the southeastern edge of this 'basin.' It is, however, significant that the southern and southwestern boundaries are missing. If, now, this 'basin' be carefully studied on a geological map,²⁶ it will be noticed that the outcrops of the various beds of the Witwatersrand system form V shapes, with their apexes pointing northeast. These contours suggest that the so-called basin really consists of an ancient synclinal valley formed by the Ventersdorp diabase having broken through, poured over, and loaded the strata of the Witwatersrand

watersrand beds. The Ventersdorp diabase and the overlying Black Reef and Dolomite formations have protected this ancient valley from subsequent erosion. The apex²⁷ of the contours of the sub-outerop²⁸ of the Main Reef series is situated 16 miles to the east of Boksburg at the head of this valley, on the Far Eastern Rand. This area appears to have been subjected to less disturbance than the rest of the Rand, for the Witwatersrand beds in this district have not been tilted at high angles, the dip varying from about 6 to 10°. The width across the syncline from Boksburg to Heidelberg is about 22 miles. It then rapidly widens, so that 26 miles farther to the southwest its width, measured southeast from Krugersdorp, has increased to 50 miles. These structural features of the Witwatersrand should be carefully borne in mind, as they have an important

²⁴Which is over 45 miles in length.

²⁵As just mentioned, L. De Launay more accurately termed it a great northeast-southwest syncline; *loc. cit.*, p. 519.

²⁶The best geological map of the Southern Transvaal is that by F. H. Hatch (1903), published by E. Stanford, London.

²⁷In plan.

²⁸The Witwatersrand beds are here covered by about one thousand feet of Dolomite, with its thin basal Black Reef formation.

bearing on the genesis of the gold in the banket, and will be referred to again when this latter subject is discussed.

The Mode of Occurrence and Origin of the Pyrite 'Pebbles'

From the early days of the Rand goldfield, the occasional occurrence of 'pebbles' of iron pyrite in the auriferous conglomerate, or banket,²⁹ has been known. The largest of them are usually only about an inch in greatest diameter. They were noticed when mining had reached a depth of 200 to 300 ft., and had passed from the weathered, free-milling ore of the oxidized zone to the 'blue' pyritic banket.

In the following pages some of the best known and most typical occurrences are described. The particular form of pyrite pebble that characterizes one of the banket lodes in the Rietfontein mines is present in considerable quantity in that 'reef,' as will be seen later from the illustrations. Other forms can also be occasionally found there by careful search. In some of the Randfontein mines various forms of these 'pebbles' can frequently be found during the progress of mining, if carefully sought; and the writer believes the same can be said with regard to Lancaster West, Lancaster, and other West Rand mines. In the Crown Reef mine the presence of the 'pebbles' was mainly confined to one particular portion of the workings. Apart from these occurrences, one may say that throughout the mines of the Rand they are rare. Here and there an occasional one has been found in the Kimberley series of conglomerates. It is noteworthy that they are fairly plentiful in the much higher geological horizon of the Black Reef series of the Potchefstroom system, in the banket at the Machavie mine in the Potchefstroom district, some 70 miles southwest of Johannesburg.

Gold-Bearing Pyrite Pebbles

From time to time these pyrite 'pebbles' have attracted attention; formerly, many observers considered them to be water-worn pebbles of pyrite.³⁰ De Launay³¹ states that "the gold-bearing pyrite is present in the form of isolated grains irregularly distributed through the silicious cement; it often forms a trail of grains, rarely continuous veinlets, around a fragment of quartz, as is observed frequently in quartz veins. The trails of pyritic grains may be either parallel to the general stratification or oblique to it; and conforming to a false bed-

ding. This pyrite, examined by a lens, or under the microscope, looks at times as if rolled or broken, this being notably the case in the parallel veinlets; more often it is well crystallized and presents sharp angles, difficult to reconcile with the idea of a prolonged trituration." Even if water-worn pyrite were originally present in the banket, it is difficult to imagine how such an easily decomposable mineral as iron pyrite could have continued to exist in these ancient conglomerates of the Witwatersrand. Especially is this so when one realizes that the original conglomerates must have been very porous before they were subjected to igneous intrusion and the consequent enormous pressure that has compressed and tilted them into their present position; and before they were cemented, or their pores closed by the deposition of secondary silica. That water-worn lumps of pyrite could have so long survived the forces of dissolution is hardly conceivable to anyone who, like the writer, is familiar with some of the enormous masses of iron pyrite mined today³² and who has seen how heavily the issuing mine-waters are charged with iron sulphate owing to the solubility of the pyrite. If indeed these 'pebbles' were water-worn and contemporaneous with the formation of the banket, then we would naturally expect that similar ones, of undoubtedly contemporaneous origin, would occasionally have been found in more recent, or now-forming, conglomerates. So far, however, as the writer is aware, none has ever been recorded. Similarly, flint occurs in the chalk beds of England and elsewhere, yet none has ever been found in the deep-sea ooze, which is its nearest equivalent at the present day, and on which so much light has been thrown by the Challenger expedition. The explanation is that the pyrite 'pebbles', or the flints, as the case may be, were formed not while the beds were being laid down, but afterward, by secondary processes. In the former case any pyrite present while the conglomerate was being deposited, owing to its easy solubility, would surely have been carried away in solution in the form of sulphates. Thus it is reasonable to assume that the pyrite now present in these beds³³ has been subsequently introduced. On the other hand, the flints are derived from the more soluble hydrous variety of silica known as opal, which was originally present as the substance of the skeletons of silicious organisms, chiefly sponges.³⁴ It seems probable that the pyrite was introduced into the con-

²⁹The conglomerates were so named on account of their supposed resemblance to almond rock, the Dutch word for which is 'banket.'

See, also, 'Remarks on the Rand Conglomerates,' by J. Kuntz, *Eng. and Min. Jour.*, Oct. 17, 1903.

Mr. Kuntz speaks of them as occurring in the Kimberley reef as well as in the Main Reef series.

Dr. Koch (of Berlin). See J. Kuntz, *loc. cit.*

George Denny, *Jour. Proc. So. Af. Assn. Eng.*, Vol. II, No. 1 (1903), p. 10.

³²Such, for example, as those that are worked at the Rio Tinto mines in southern Spain, where the iron pyrite occurs as metasomatic contact deposits, which contain a little over 2% of copper, and are exploited for copper and sulphur.

³³As already stated, according to A. F. Crosse, the average amount of iron pyrite present in the auriferous banket of the Rand varies from about 2 to 3 per cent.

See, also, 'The Mode of Occurrence and Genesis of the Carbon in the Rand Bankets,' by C. B. Horwood, *Trans. Geol. Soc. So. Af.*, Vol. XIII (1910), p. 72. L. De Launay, *loc. cit.*, says the pyrite forms fully 5% of the weight of the rock. The present writer considers Crosse's estimate as the more accurate.

³⁴For 'The Origin and Formation of Flints,' see 'The Age of the Earth,' by W. J. Sollas (1908), chapter VI (T. F. Unwin, London).

glomerate at a late stage, while the conglomerate was still pervious to mineral solutions, and yet sufficiently near the time of final cementation to have insured its preservation from attack and dissolution by still more recent solutions. Later we shall see that the pyrite forming the pebbles is secondary, and was introduced long after the formation of the banket.

The writer's studies of this subject have extended over the last seven and a half years. His observations were made first-hand, underground, during the stopping and development operations of ordinary mining work, which afforded exceptional opportunity for continuous inspection of the various 'reefs' while fresh exposures of them were being laid bare. These have been supplemented by the collection and examination of a large number of specimens taken at the actual working faces in various mines, and also by detailed petrological work, including the microscopical examination of a great number of slides.

Pyrite Pebbles at the Crown Reef Mine

In a paper read before the Geological Society of London in February 1907,³⁵ he described an occurrence of these 'pebbles' that had come under his notice about the end of the year 1905, in one of the gold-bearing conglomerate beds of the Crown Reef mine, near Johannesburg. He showed that they had been formed in place by metasomatic replacement of quartz; and, at that time, expressed the opinion that they were pseudomorphs after quartz pebbles. This view was a new one, advanced for the first time; and it met with a considerable amount of opposition.³⁶

At that time the writer had no slides of these pyrite 'pebbles' for examination under the microscope. Since then he has had several sections made, but it will be advisable first, before describing them,

³⁵The Occurrence of Pseudomorphous Pebbles of Pyrites at the Crown Reef Mine (Witwatersrand), *Abst. Proc. Geol. Soc. Lond.*, March 5, 1907. On March 18 of the same year, R. B. Young read a most interesting paper before the Geological Society of South Africa in which he described, in some detail, the pyrite nodules occurring in the Battery reef (a local name for the Kimberley reef) at the Lancaster West mine, on the Far West Rand, and concluded that they had been formed by the replacement of the quartz of both pebbles and matrix, and that their ellipsoidal shape was not pseudomorphous, but a direct result of the mode and conditions of their growth. He does not, however, attempt to explain how or why their shape is a consequence of their particular condition of growth. 'Notes on the Auriferous Conglomerates of the Witwatersrand,' *Trans. Geol. Soc. So. Af.*, Vol. X (1907), pp. 17-30; see also reference to this in 'Further Notes on the Auriferous Conglomerates of the Witwatersrand, etc.,' by R. B. Young, *Trans. Geol. Soc. S. A.*, Vol. XII (1909), p. 88.

³⁶Ernest H. L. Schwarz, of Rhodes University College, Grahamstown, in the Cape province of the Union of South Africa, was one of the few who agreed with the present writer. In a letter written to him at the beginning of April, 1907, he wrote: "I notice that you have given a paper to the Geological Society, London, on the pyrites pseudomorphs in the Rand Banket. I much rejoice that you adopt this view. I worked out the question a short while ago and came to the same conclusion; see Records, Albany Museum, Vol. I, pp. 387-395, 'Notes on a Quartzite Boulder from the Molteno Beds.' See also C. H. Smyth, *Amer. Jour. Sci.*, XIX (1905), p. 277, on a similar case in the Onelda Conglomerate."

to give a brief description of the conditions under which the 'pebbles' exist in the banket. This description furnishes a clue to the solutions that dissolved portions of the silica and precipitated pyrite in its place.

At the Crown Reef mine, in a stope³⁷ between the 600 and 700-ft. levels, 'pebbles' of iron pyrite were found at the base of the Main Reef Leader (a thin bed of conglomerate immediately overlying a band of shale), and in close proximity to a diabase dike. The length of the stope was about 130 ft., and the bottom of it was 630 ft. vertically below the surface. The 'reef' or lode dipped south at an angle of 38 degrees.

In this stope the matrix of the Main Reef Leader was very pyritic, especially at its base. The Leader was from 9 to 10 in. wide, and was underlain by a thin but persistent band of shale, which averaged 2.8 to 3.5 in. thick. Small stringers of quartz, running parallel to the bedding, occurred here and there in the shale band, affording evidence of the action and course of former mineralizing solutions. Immediately below this shale was the bed of conglomerate known as the Main Reef, which in this mine varied from 10 to 15 ft. in thickness, and, except occasionally in places, is poor in gold. In mining the overlying Main Reef Leader, a portion of the Main Reef was also extracted, it being impossible to carry the stopes sufficiently narrow to remove only the Leader.

The Crown Reef Dike

The dike, known as the Crown Reef dike, was black in color, of very basic character, highly decomposed, and had developed,³⁸ parallel to its strike, a shaly fissile structure. The intrusion of the dike was accompanied by a reversed faulting movement,³⁹ which threw the beds up a distance of 76 ft. on the south side, so that the South Reef series on the north side was exactly opposite the Main Reef series on the south side of the dike. At the bottom of the particular stope in which the pyrite 'pebbles' were found, and at the contact of dike and banket, on the north side of the former, the dike was altered for a thickness of about three inches into a light bluish gray clayey decomposition product, and was here, where it passed through the lower end of the east face of the stope, about 40 feet wide. Its strike was approximately 16° north of east, and south of west; it was almost vertical (near the surface it was slightly overtilted and dipped about 88° north); it could be traced throughout the mine, that is, for a distance of about 3000 ft.; and it extended westward into the Langlaagte Estate mine. Its average width in the Crown Reef mine was about 35 feet.

At, and for some 20 ft. from, the dike contact, the shale underlying the Main Reef Leader was changed into a yellow brittle flaky porcelainite; above this it gradually assumed its ordinary character.

³⁷The designation of this particular stope was 4 B.W.E. (north of the dike).

³⁸Doubtless due to pressure.

³⁹De Launay pointed out that the principal faults on the Rand are strike-faults accompanied by reversed faulting, indicating pressure from the south at right angles to the strike of the beds (*loc. cit.*, p. 519).

A few 'pebbles' of pyrite occurred at the immediate contact of dike and banket, and for about 10 ft. from the former; above that they were of frequent occurrence as far as the top of the stope.⁴⁰ Similar pyritic 'pebbles' were also occasionally found farther away from the dike, on the western face of the stope, as also in the stope immediately below. These 'pebbles' varied in size, up to one inch, in greatest diameter, they were mostly circular, but some were oval, and they were all well rounded. When fractured, they sometimes showed an internal radial fibrous structure, which of itself is sufficient evidence that they were formed in place and are not water-worn pebbles. Some, even in hand specimens, showed that the quartz of the original pebbles had not been entirely replaced, and, in others, the pyrite could be seen entirely surrounding the quartz, and, as it were, eating into it, so that if the pyrite were removed, what were undoubtedly originally smooth water-worn pebbles would present irregular, fretted, and corroded surfaces.

(To Be Continued.)

Malay Tin

The Federated Malay States have recently come to attain name and fame as the producers of a large percentage of the world's supply of tin. The Chinese were the earliest discoverers of tin, but they worked the land in a primitive way. Later British miners, adopting scientific methods, have developed the industry to its present magnitude. At the present time there is still some alluvial tin mining, but the rich mines are the lode workings, chief of which are the Trenoh, Ula Pia, Kramat Pulai, and Tekka Limited. These rich mines are confined to the state of Perak and principally controlled by officers in the town of Ipoh, Destrien Kinta. But tin is not confined to Perak; throughout the Federated Malay States there exists tin, and many a rubber plantation is growing on land which could more profitably be worked as a mine, for where rubber means much initial outlay and the employment of a large number of coolies, a tin mine needs a comparatively small outlay. The days when tin mines were worked with expensive overhead machinery have passed, and today the one and only system is hydraulic power. A strong pressure of water ejected through a monitor does all the work. This disintegrates the soil, which is pumped up in a semi-liquid mass to flumes elevated to as high as sixty feet, with a small incline, and at every six feet or so is a riffle which obstructs the progress downward of the heavier mineral. Small particles do escape, but not for long, for the water is screened below in a reservoir, which is an important operation; even the water is not lost, but passes on to a pond to render further service as required. The value of the sediment in these ponds is something yet to be calculated. A side issue at mines is the tributary system. Land not actually being worked is let out to Chinese and Malays and the result of their work is bought by the operators. There is no expense to the company and the gain is considerable,

⁴⁰They seem to be especially numerous about half way up the stope.

but it would not be good practice to work a mine purely on the tribute system. The land will suddenly become unproductive and later these abandoned properties have returned the largest dividends. It is not uncommon for a few yards to yield as much as 75% of tin and immediately adjacent similar land to be absolutely barren.

Some mines, like the Lahat, six miles from Ipoh, adopt the puddling principle before the soil pumped up passes into the channels. It is more expensive, and no doubt the thorough liquifying of the soil does render the subsequent work easier, but, all things considered, the difference is small. Women are only employed in working with the stream of tin after passing over the riffles, and a dozen is sufficient. Experience is an important factor in tin mining, and the Chinese are born to the business. Even Chinese women may be seen by the hundreds examining the water running through the drains adjoining mines in search of tin, and they must realize some profit or they would not be working at it from early morning to dark.

The regulations affecting mines in the Malay States are all in favor of the worker. He must be housed and fed, and a hospital provided on the premises, with a doctor visiting the hospital daily, otherwise there are severe fines and penalties. The Government is naturally rich. It toils not neither does it spin, but it waxes rich in royalties and taxes, but for the present the miner does not demur, as he is also prospering. At Penang and also at Singapore are extensive smelting works, where their agents are buying freely throughout the Malay States. Nearly every tramcar passing the works stops to pick up a wagon laden with ingots of tin, while hardly a ship leaves either port without a large cargo.—*The National Review*.

Titaniferous Iron Ores of the United States

One of the problems that confronts American ironmasters is the efficient reduction of magnetite containing a high percentage of titanium, as ores containing over 1% of titanium are troublesome to smelt in the blast-furnace. From time to time the discovery of enormous bodies of workable titaniferous ore has been reported, and the available literature dealing with the geologic occurrence and the economic value of the titaniferous magnetite in the United States contains a mass of information that in part is based on incomplete observation and even on hearsay. In an attempt to ascertain just what the economic possibilities of the larger deposits of titaniferous iron ore may be, the Bureau of Mines took up the study of the possible utilization of these ores through some concentrating process. The conduct of this investigation was assigned to J. T. Singewald, Jr., and the results are presented in Bulletin No. 64, which may be obtained from Washington, D. C. "It is to be regretted," says J. A. Holmes, of the Bureau of Mines, "that the results of Mr. Singewald's careful study of the ores are chiefly negative. Some deposits of titaniferous iron ore are clearly not as extensive nor as high in iron as they were reported to be."

Revision of United States Mining Laws

By HORACE V. WINCHELL, C. W. GOODALE, and M. L. REQUA

*No argument is needed to convince a man of the importance of his own chosen profession. Familiar with its traditions and its history, knowing its progress, and having himself contributed to its development, he is inspired by the greater achievements of his colleagues and is impressed with its importance in human affairs. It is possible, however, to be so engrossed in the details and routine of every-day work as to lose the perspective of the profession as a whole, just as a spectator in the grandstand who knows nothing of the technique of a horse race may yet have a much more comprehensive view of its progress and the conditions surrounding it than any one of the scientifically trained contestants. Thus, even when it is generally realized that there is something wrong with the body politic, very few members of that body are equal to the task of diagnosing the trouble and prescribing the proper remedy.

Even with a widespread feeling that our present system of mining law is defective, and a general demand for its revision, it would still not be surprising if it should develop that mining engineers have not as yet united in a concrete, well-developed conviction as to the remedies indicated, and the course of treatment to be adopted. It will be admitted that it is not an easy task to cover all conditions and all minerals in all lands and under different climates with one statute. It may be possible, however, to agree finally upon some of the fundamental principles which are most wholesome for the mining industry and which should find expression in the laws under which it may be inaugurated and conducted.

It should be stated at the outset that the mining laws referred to in this discussion are those which concern the title or possession of minerals and ores, and the lands in which they are found, as distinguished from mining regulations which govern the operation of mines and the relations which exist between labor, landed proprietor, and the government.

Proprietorship of Ores and Minerals.

Different fundamental conceptions as to the title to ores and minerals are developed in the laws of various countries. Indeed, the progress of human civilization is said¹ to find an expression in the mining laws from time to time enacted by different governments. Since ores are valuable only after they have been severed from their birthplace in the ground, and adapted for the use of man, from time immemorial a difference has been noted between a title to land and that to the mineral wealth which the land contained. Lands might be granted or leased, but the metallic treasures beneath the surface were subject to the separate control and disposition of the reigning authority. Especially was this true

of the metals gold and silver, which were wholly the property of the crown "for the purpose of coinage and to support its dignity"² in nearly all European countries; and in many of them it persists, at least in theory, to the present day. This regalian right "followed the principles of the civil law, by which it was established that the ownership of all lands was primarily vested in the state," and that "all mines of gold and silver in public lands belong to the state or sovereign as a part of the sovereign patrimony; whence it followed that the right of severance could be exercised" and the minerals and land granted separately. By the rule of the common law from the earliest time the owner of the soil owned all beneath it with the limitation only that royal mines belonged to the crown.³ In many of the royal grants to the colonies forming the original thirteen states there was an expression of this theory of regalian right, and a reservation of a fixed portion of all the royal metals discovered.⁴ The Virginia charters reserved likewise one-fifteenth of all copper. It is only occasionally and for brief periods of time, however, that one finds governments or monarchs attempting to extend their royal rights over the baser metals and coal (although the salt deposits are still held as government monopoly in several countries).

State and Federal Proprietorship

In the United States there are two different kinds of sovereign proprietorship of minerals and mining rights, state and federal. The original thirteen states derived their rights prior to the formation of the federal government. Other states have at various times and in different ways acquired rights.

The mining laws which are the subject of this discussion are those federal statutes which control the prospector and miner in discovering and acquiring title to deposits upon the public domain in the states and territories and possessions which come within the scope of such laws. It is known to every intelligent dweller upon this continent that by far the largest part of our gold, silver, copper, and lead comes from the mining states, west of the Missouri river, and the importance of legislation which will encourage and promote the discovery and development of more mines is emphasized by every political economist. The best mining laws are those which result in the greatest good to the greatest number for the greatest period of time, and which lead to the largest output and consumption of mineral products with the smallest amount of waste. It is to the interest of all the people to see that such laws are enacted; but since the people at large are not so well versed in those matters as the mining men themselves, it is the latter who should take the initiative whenever new conditions create the necessity for new laws.

Necessity for Revision.

As to the need for mining law revision there seems to be no doubt whatever. Congress has been memorialized by our greatest statesmen and economists, by presidents, cabinet officers, and directors of the land department and of the geological survey, associations of commercial and mining men in all parts of the land have voiced the necessity, and committee after committee has formulated its suggestions and presented them to a heedless congress. Mining journals have teemed with articles upon the subject; prominent attorneys and jurists have discussed it; the expensive and sometimes disastrous apex litigation in almost every mining district, where the mine proprietors have not prudently by mutual agreement nullified the extralateral right provision of the statutes under which their title was acquired, has attracted widespread attention to some of the worst defects in our present law until scarcely anyone attempts to defend it; and yet nothing is done.

It is often a simple matter to criticize and point out defects, but a far more difficult task to suggest constructively what should be done to improve the situation. If, however, it is possible to single out weak points and hold them up to the light of criticism there shall at least be performed a work necessarily preliminary to that of finding the remedy. Let us first, therefore, consider some of the bad features of our present law.

Lack of Protection to Prospectors.

It is a custom which, like many others, has been sanctioned by legal enactment in many countries, to reward the discoverer of a new vein or mineral deposit, or a new mining district. Sometimes this reward is offered in the nature of a cash bonus, but it more frequently takes the shape of permission to locate for himself a larger claim than is allowed to subsequent locators. In the attempt to incorporate this principle into our mining law every right was made dependent upon a discovery of ore in place, and until such discovery the prospector has no possessory rights. Instead of being permitted and authorized by law to stake out his ground wherever he chooses on the public domain (in many countries this right is extended also to private estates, and the owner is compelled to grant a prospecting permit to any applicant unless he wishes himself to explore his own ground) and there, under proper conditions as to continuity of work, being protected in his exclusive right to explore, he is actually an unlicensed, unauthorized, and unprotected trespasser until he has discovered "veins or lodes of quartz or other rock in place bearing gold, silver, cinnabar, lead, tin, copper or other valuable deposits."⁵

Upon this point, W. L. Fisher, recently Secretary of the Interior, speaks as follows:

"It is becoming increasingly evident that the lode mining law needs changes in one respect, at least. The law at present does not provide for the creation of any rights in supposedly mineral land, except by the issuance of patents, and in that regard congress has provided that a patent can follow only on a legal location and has said 'but no location of a

mining claim shall be made until the discovery of the vein or lode within the limits of the claim located.' As long as Congress desires to adhere to the policy at present embodied in statute law of disposing of mineral land absolutely, the law quoted above tends fairly well to the development of mineral properties where the ore can be discovered at or near the surface of the ground, but it seems to be ill-calculated for a district where, as is the case notably in some of the copper mining districts, the ore lies at depths of hundreds and sometimes thousands of feet. The expense of actual discovery of the vein or lode within the limits of any particular claim in such cases involves deep exploration, either by drilling or by the sinking of a shaft from the surface, or the extension of a tunnel into the claim. Either of these operations may involve great expense, and it has been repeatedly urged on the department that investors are reluctant to spend the money required without further assurance than the law as it reads at present can give them. On this ground the department has been strenuously pressed to so construe the law as not to require the actual discovery of the lode which is supposed to exist within each claim, but to patent the claims upon evidence of the existence of mineral at or near the surface wholly disconnected with the supposed lodes below and of no value in itself, either present or prospective, it having been further urged that in these cases it was a matter of geological inference that ore bodies did exist far below the surface.

"It is obviously the duty of the department to carry into effect the intention of Congress expressed in statutory form. Congress having said that no lode claim should be patented without discovery of the vein or lode, within the limits of the claim, it would be an evident usurpation of power for this department to patent lode mining claims without proof of actual discovery. The frequently repeated assertions that the recent rulings of the department have overturned interpretations placed upon the law for 30 years seem utterly without foundation, as is pointed out in the recent departmental decisions. On the contrary, had the department decided that it could dispense with actual discovery it would have overturned the practically unanimous holdings both of the courts and of the department ever since the enactment of the lode-mining law. Doubtless in some cases claims have been patented where there was little or no proof of actual discovery, but the patenting of such claims is evidently to be laid to a misapprehension of the facts by employees of the land office, and not to a misconstruction of the law by the department.

Relation of Law to the Prospector

"It seems, however, possible by a change in the law to keep in force the policy of the Government expressed in the mining law of rewarding the actual discoverer of valuable veins, while at the same time giving such protection during the work preliminary to actual discovery as would make it possible for capital to invest, taking no more risk than that inherent in the question whether there is or is not in fact valuable mineral in the place where it is sought.

⁵Rev. Statutes U. S., Sec. 2320.

I suggest that the law should be amended so as to give a prospector, for a term of years, an exclusive right of possession and of prospecting within a limited area of land. In case actual discovery were made within the time given, patent would issue. The prospector should be obliged to perform a reasonable amount of work during the existence of the permit in order to make evident his good faith in attempting to find mineral within the limits of the claim. He should, however, be given the right by proper proceedings, to settle disputed questions of intervening claims, both in case of conflict with other mineral claims and also cases of conflict with agricultural claimants, so that he might at the earliest possible moment know whether or not his title would be absolutely clear upon his making discovery."

Location of Lodes Within Placers

Placer mines are likewise located by discovery and held by annual work and acquired by purchase in fee simple forever. Known veins within placer locations must be declared and paid for separately; otherwise they are excepted from the placer patent and can be located by others in 'lode claims.' All veins on placer ground not known to exist at the time of application for patent belong to the grantee, but without extralateral or apex rights. If an applicant for a placer patent can be shown to have had knowledge of a valuable lode within his lines prior to the making of his patent application, his title as to that vein may be cancelled for fraud at any time upon application of a contesting locator. There is no limit to the time for such contests, and they are still being brought in some cases 20 years after the placer patent was granted.

The law is very defective on this point; for it frequently happens that veins discovered today have a value by reason of improved transportation facilities or metallurgical processes, although these same veins were of no value whatever when the placer claim was located and patented. The owner of such a claim is sometimes put to the expense and annoyance of defending such contests repeatedly, since there is no limit to the number of contestants. The law should be amended so as to make it impossible to attack a placer patent on such charges after a reasonable term of years.

Multiplicity of Claims Locatable

Another defect in our present law is that permitting a prospector to locate an indefinite number of mining claims and to hold them without actually doing his assessment work. Many promising districts are kept from becoming hives of industry and producers of mineral wealth by the tying up of their territory in this way. The prospector should be restricted in the number of his locations, and real development work should be exacted.

Faulty Provision for Recording Claims

Still another weak point in our present system is in the provision for recording notices of location. It frequently happens that mining claims are located within the boundaries of some railroad or other land grant. The locator files his notice in the office of the local recorder, and the railway company files its

selections with the Commissioner of the Land Department at Washington. Both selections are approved or at least allowed to stand, perhaps for years, each claimant believing his equitable title unclouded until an application is made for patent. Then a contest ensues, bitter feelings are engendered, and much money is needlessly spent because of the imperfect statutory provision for filing notices of location.

Lack of Provisions for Appeal

Still another serious defect in the United States and Alaskan mining and land laws is the lack of any provision for appeals to the courts from the decisions of administrative officers. It is contrary to the general spirit of our institutions and an anomaly in constitutional government to take away from any citizen property rights to which he considers himself justly entitled under the law, by the mere fiat of an appointed government official who is here today and gone tomorrow. To place in the hands of such officers the final dicta in matters involving property valued at hundreds of thousands of dollars, and to provide no method of appeal to any duly constituted nonpolitical judicial tribunal, is not only to subject the said officials to great and unnecessary tests of moral courage and fidelity, but to require in them the qualifications of superior judges and an experience in the interpretation of the law which many of them cannot be expected to possess. Serious injustice may be done without any remedy at law to the defeated applicant. In the interests of justice, provision should be made for appeals in important cases, and perhaps in all cases, from decisions of the commissioners of the General Land Office, or of the Secretary of the Interior, to some court of competent standing and jurisdiction, whose decisions could and would be accepted by the public and the interested parties as justified by the law and the evidence.

Extralateral Rights

The crowning absurdity of our present mining law is what is known as the apex provision, which permits the owner of the outcrop of a vein to follow it on its downward course into the earth and beneath the surface of property owned by another. This is the law that has made us famous among miners the world over. Not that the practice originated here, for it was tried by the medieval Germans and abandoned, as is said by an authority on Prussian mining law because "interminable lawsuits were inherent in the system," and it was in force in British Columbia for a brief period and likewise abolished; but it has been held here for half a century or more, and although our reputation for progress and right thinking is fairly high, the miner is burdened with this pernicious principle. Opinions without number could be quoted against it and but seldom one in its favor.

Hoover says:⁶ "Lest the Americans think that the apex law was a sin original to themselves, we may mention that it was made use of in Europe a few centuries before Agricola."

George Otis Smith, director of the United States

⁶Hoover's 'Agricola,' p. 83, footnote.

Geological Survey, says:⁷ "The law of the apex has proved more productive of expensive litigation than of economical mining."

A. Montgomery, state mining engineer of Western Australia, who is certainly well qualified to express an opinion, says, in a letter to your committee: "The extralateral right principle obtaining in portions of the United States is a standing marvel to the rest of the world, and that it could be seriously proposed to perpetuate it outside of cases in which it has already been unfortunately granted, seems incredible to most outside engineers with whom I have come in contact."

Many others have expressed themselves to us in a similar vein, and a synopsis of their views accompanies this report. From the replies thus received in answer to letters sent out by the committee one is convinced that the sentiment of mining men is overwhelmingly opposed to it in principle, and that the majority, although not so large, is in favor of its repeal at as early a date as possible.

Miscellaneous Defects

There are many other shortcomings in our present law. There are no adequate and proper provisions for the location and operation of oil wells, phosphate deposits, rare earths, haloids, and many other mineral substances. Our coal land laws are imperfect; the petroleum and natural gas resources should be safeguarded; assurance should be given as to the titles already granted, and the prospector should be again encouraged to go upon the public domain and discover additional treasures for the benefit of himself and the nation at large.

Recommendations

This committee has not felt called upon to make any attempt to draft a new code of mining laws, nor does it feel competent to do so. Such a task might engage the attention of a commission of business men, mining engineers, and attorneys, all selected because of their peculiar qualifications and experience in such matters. Indeed there is ample material to occupy the time of such a commission for at least one year in working out a harmonious scheme by which all interests should be properly subserved and the best results obtained. The committee gathered together a library on the subject of mining laws and have investigated the statutes of many countries, and it has seemed best at this time simply to call for an expression of opinion from members of the Society on certain elementary principles. In this way it will be possible for us to arrive at a correct conception as to the framework on which may later be built a complete structure. The committee begs to submit for the consideration of the Society the following recommendations, in the form of a series of resolutions:

1. The mining law should be revised, not piecemeal, but thoroughly, so as to coördinate and harmonize its various provisions.

2. Mining claims should be locatable regardless of a 'discovery' and held only so long as the specified development work is performed.

3. Placer locations should be limited to deposits

of loose material above solid bedrock. The locator should have a preference right to locate also any lodes developed on his placer ground.

4. A statute of limitations should establish a reasonable term of years beyond which placer patents shall be immune from attack on the ground of fraud.

5. Provision should be made for the location and working of petroleum, phosphates, rare earths, haloids, and other mineral substances not specifically mentioned in the present law.

6. Full privilege of appeal to some competent court of law should be provided for in all cases of contests between rival claimants, or between a locator and the Government.

7. Notices of mining locations should be so recorded as to give the fullest possible notice to the world and to all concerned.

8. The apex law should be abolished.

9. Existing titles should be reaffirmed and fully recognized and no effort should be made to create retroactive legislation.

10. For the purpose of giving the fullest consideration to the needs of every branch of the mining industry in every part of the country, it is desirable that a government commission be created by act of Congress, whose duty it shall be to investigate by every proper means the questions and interests here referred to, and to make recommendations as a basis for the proposed mining law revision.

Unremunerative Rand Mines

Of the fifty-three mines which declared outputs to the Chamber of Mines in respect of the June, 1913, operations, twenty have not declared dividends for the first half of the current year. Of these the Lancaster merely recorded a small final clean-up, while the Spes Bona is a privately owned concern. The eighteen others had a capital in issue of over fifteen millions sterling. The name of the New Kleinfontein might also be added to the list. This concern, although it did not declare any output for the month on account of the strike, is under normal circumstances a regular producer of gold, the capital in issue being £970,000. Those who are loud in their denunciation of the mining companies as mere dividend-earning machines for foreign capitalists would do well to take the figures to heart. At most of these mines the margin of profit is very small, while the grade of ore is such as to admit of little possibility of improvement. In the event of further serious depletion of native labor complements the majority of the mines noted would have to close down immediately, and it is certain that a number of them would not resume operations. The effect of the application of closure at these mines would inevitably react on the workers themselves. The obvious consequences would be so appalling that it is difficult even at this time to imagine that the labor leaders will urge the continuation of a fight which must inevitably throw hundreds of white workers permanently out of employment as well as destroy confidence in the mineral industry of the Rand.—*South African Mining Journal*.

Waste Heat Boilers in Reverberatory Furnace Flues

By S. SEVERIN SORESEN.

As there are probably few of those who are interested who are also in a position to make comparisons of actual results between two leading types of boilers when used to recover heat from the flue gases of metallurgical smelting furnaces, the following notes may be useful.

Stirling and the Babcock & Wilcox Boilers

The types here compared are the Stirling and the Babcock & Wilcox. The former are very widely

The illustrations show the settings of the two types of boilers in elevation. Inserts A-A and B-B show the arrangement of their tubes by cross-sections on planes parallel to the flow of the gases. As far as constriction of the passage and cutting down of draft goes there is a little in favor of the Stirling type. When it is remembered that they were originally introduced in coal fired plants where draft is possibly both more essential and more sensitive, one reason for the favor they have enjoyed is explained.

FLUES AND BOILER SETTING, STIRLING BOILER, STEPTOE VALLEY S. & M. CO., M'GILL, NEVADA.

used for this special purpose in copper smelters because of their large flue gas area and small obstruction to draft. They are specified as class 'S' No. 19 and are 400 nominal boiler horsepower each. There are no baffles used in setting, the gases only taking one curved pass through the tubes before leaving.

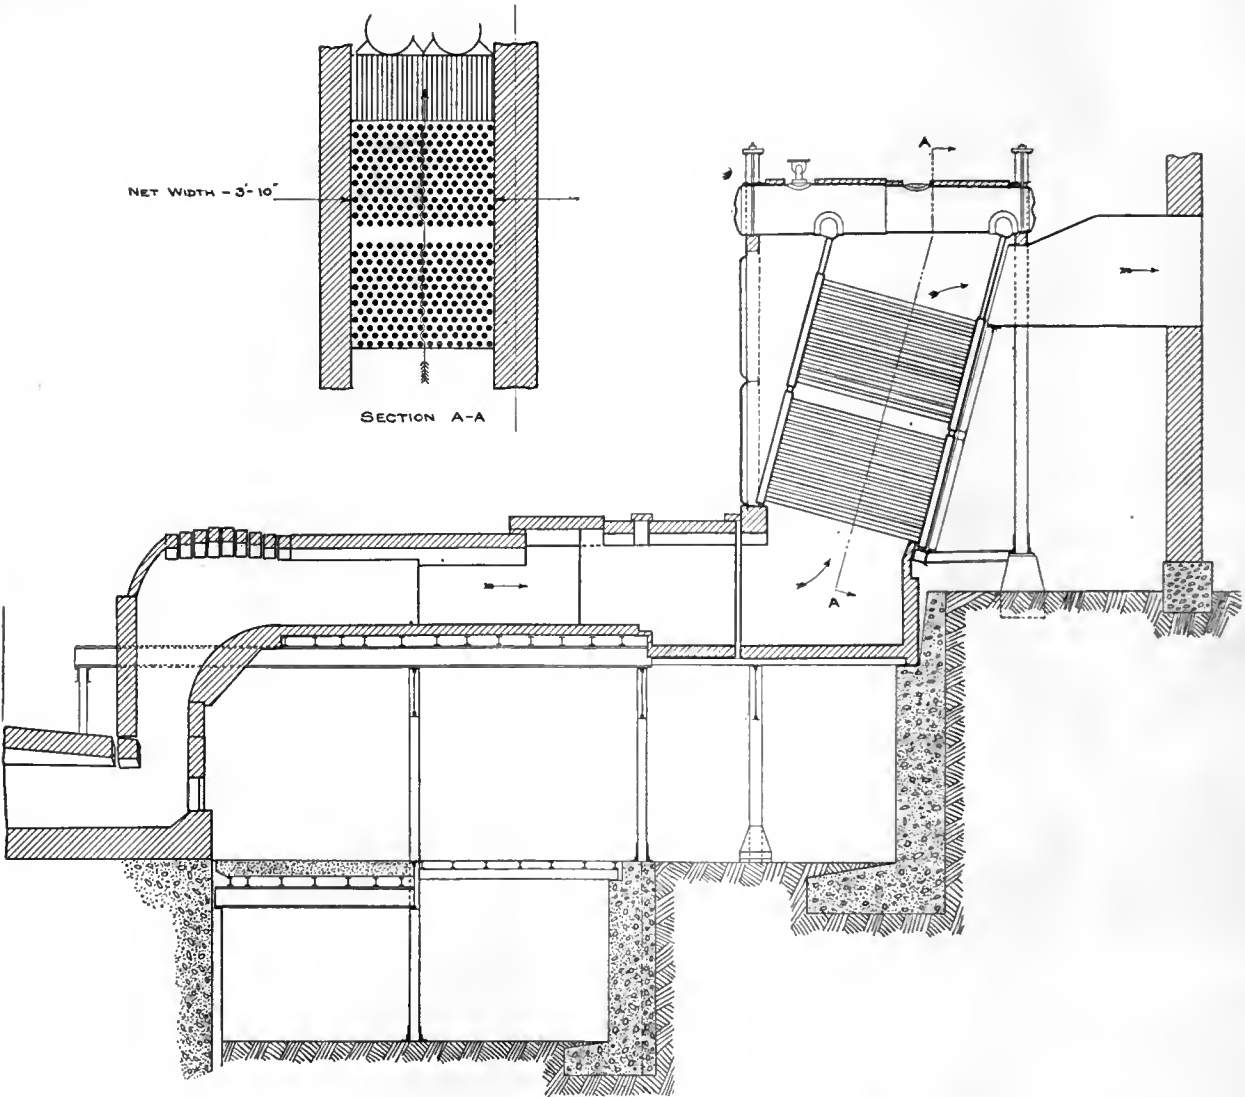

The Babcock & Wilcox are a specially designed pattern for this particular installation, described by them as $\frac{14-26}{2-36}$ —10—D, each having 4054 square feet of heating surface. No baffles are used in them either but their rows of tubes are staggered in respect to the flow of the gases, which is not the case with the Stirlings. The latter have straight open passages between rows of tubes. This is rendered necessary in order to provide means of getting their bent tubes in and out for repairs.

It will be noted that the Babcock & Wilcox tubes lie flatter than the average of the Stirling bent tubes. The latter are $3\frac{1}{4}$ in. diameter and the former 4 inch.

In the early days of this plant I was in favor of the Stirlings because they were so much more quickly accessible for cleaning, having only four manholes to remove against 732 hand-holes each of which had a gasket to be removed and renewed. It thus took longer and cost more in direct charges for cleanings and repairs. In addition to the direct labor and material charges there was the extra time lost in the case of the Babcock & Wilcox boilers, which took longer than the Stirlings to clean. This extra time meant a loss when the cleaning was not done within the time required for repairs by its smelting furnace. So it looked like a walk-over victory for the Stirling

type. For a long time this conclusion held undisputed sway, for in the absence of data it was based on the assumption of equal efficiencies of the two types. It was only after separate meters for measuring the feed water to each battery of boilers were obtained and comparisons of evaporative performances were made that it was seen that the Babcock & Wilcox were giving a higher evaporative duty. At first I suspected the figures. But having changed meters and checked results in various ways the truth was borne in on me that the money was being put on the wrong horse. For the higher evaporation obtained from the Babcock & Wilcox boilers far

more than compensates for the extra cost and extra time lost in cleaning and repairing. In proof of this conclusion I append the figures on which it is based. They speak for themselves. I may add that the meters are calibrated every month at various rates by gauging in a measured tank, allowance being made for temperature differences. From the meter readings a deduction is made for blow-downs which are made and automatically recorded twice every 8-hour shift.

	Babcock & Wilcox.	Stirling.
Period covered in comparison, year....	1912	1912
Number of boiler repairs.....	11	23
Average cost of repair and cleaning per repair, opening, cleaning, closing, testing	94.54	54.75

Average boiler horsepower	520	375

Total loss and cost per 100 days.....	2,683.39	1,612.69
Net recovery in 100 days.....	25,024.61	20,172.31
Balance in favor of battery Babcock & Wilcox type, per annum.....	17,710.90	

Other figures point to the same conclusion. For, with the same assumptions and the same methods in

testing, checking and figuring, the pounds of water evaporated from and at 212° F. per pound of oil burned in the smelting furnaces was 3.315 for the Stirling boilers as against 7.91 for the Babcock & Wilcox type. To show that this was not due to deferred combustion favoring the boiler duty at the expense of the furnace smelting through faulty firing it is only necessary to state that for the same period the net oil per ton solid charge for the furnace with the Babcock & Wilcox boilers was only 77% that of the others with the Stirling. It is true the former burned 5% more oil gross per ton solid charge than the others. This may be due to inferiority of the furnace. But it is evident from the above figures

that it more than compensated for that extravagance by its greater net efficiency.

From an examination of the two settings as shown in the sectional elevation in the illustrations it is evident that apart from the staggered as opposed to the straight line setting of the tubes the Stirlings lose by reason of the larger percentage of comparatively ineffective tube lengths. This might be improved both in front and at the back where structural conditions and levels permit. And on the other hand the Babcock & Wilcox records for cost of cleaning and repairing could be improved were the hand hole joints of the metal to metal type instead of being made up with fabric gaskets.

The Electrolysis of Cyanide Solutions

By EDWARD F. KERN.

*The experiments upon which this article is based were conducted by E. H. Koenig and S. E. Woodworth in the Metallurgical Laboratory of the School of Mines of Columbia University. The work was undertaken with the idea of determining the validity of some of the conflicting statements which were found in reviewing the literature on the electrolysis of cyanide solutions.

The electrolysis of cyanide solutions which are used for the treatment of gold and silver has caused much speculation, not only on account of the application of electrolysis as a means of recovering the gold and silver from leaching solutions, but also as a means of regeneration of the cyanide. Two of the main items of expense of the modern cyanide process are the consumption of cyanide and the cost of recovering the gold and silver in a fairly pure state.

Electrometallurgists and electrochemists, having in mind the reduction in cost of treatment of gold and silver ores, have developed a number of processes in which electrolysis has been applied for the recovery of metals from leaching solutions and for the regeneration of the cyanide, which during the treatment has been converted into cyanide compounds whose solutions do not dissolve gold and silver.

Conclusions from the Literature on the Subject

The conclusions, which may be drawn by making a digest of the literature on the electrolysis of cyanide solutions, are as follows: 1. Electrolysis has, under favorable conditions, been utilized as a means of precipitating and recovering gold and silver from cyanide leach solutions by electrolyzing the solution with suitable electrodes and with a current density of 0.01 to 0.6 ampere per square foot (0.11 to 6.5 amp. per square meter). The metal was deposited as a dense film when the current density was properly regulated with regard to the composition, the concentration, and the circulation of the solution. The deposit formed is pulverulent and non-adherent if the solution is dilute, the circulation sluggish, and the current density high. 2. Iron anodes dissolve in

cyanide electrolytes, causing consumption of cyanide and contamination of the solution by precipitates of iron compounds. 3. Carbon and graphite anodes are satisfactory in cyanide electrolytes when used at low current density, but they disintegrate at high current density, causing fouling of the solution. 4. Peroxidized lead anodes are not dissolved during electrolysis of cyanide solutions, and the consumption of cyanide by their use is less than when metallic iron anodes are employed. 5. Fused iron oxide anodes are permanent in cyanide electrolytes, and the cyanide consumption by their use is small. 6. Oxygen, supplied to cyanide leaching solutions either by additions of chemicals or by electrolysis, is beneficial for the treatment of certain refractory ores, in that the extraction is thereby accomplished more rapidly and more efficiently. Electrolysis is claimed to be a cheaper and more efficient method of supplying oxygen to cyanide leaching solutions than by the addition of chemical oxidizers. 7. Regeneration of cyanide work solutions, which contain cyanogen compounds, is possible by electrolysis. There is controversy as to whether alternating current can be used for this purpose. 8. Electrolysis of solutions containing sulphocyanide and cyanimide by means of direct current at high current density (50 amperes per square foot, 540 amperes per square meter) produced solutions of cyanide. Fused iron oxide anodes were found to be the most satisfactory for this purpose. 9. Electrolysis of solutions containing only cyanide produces cyanates, which will not dissolve gold and silver. 10. Telluride gold ores were effectively treated by use of solutions which contained an halogen-cyanide compound, which was generated by electrolysis of solutions containing an halide salt and cyanogen compounds, employing direct current at high current density for producing the active halogen-cyanide compound.

Experiments.

The object in view, when the experiments were undertaken, was to determine: (1) which kind of anodes are the most permanent, and which kind give the highest efficiency as regards the regeneration of cyanide solutions; (2) whether the electrolysis of

*Abstract of paper presented at the twenty-fourth general meeting of the American Electrochemical Society, at Denver, Colo., September 9-11, 1913.

cyanide leaching solutions is beneficial in increasing the extraction of gold and silver from ores, and in reducing the cyanide consumption; (3) whether high or low current density produces the greatest amount of active solvents in cyanide leaching solutions, the active solvents being those which are active in dissolving gold and silver; (4) whether a relative difference in current density at the anode and the cathode affects the consumption of cyanide, and what effect this relative difference in current density has upon the production of active solvents in cyanide solutions; (5) what effect the alkalinity of cyanide leaching solutions has upon the results of electrolysis; (6) whether electrolysis of cyanide leaching solutions is beneficial in reducing the time required for the efficient treatment of gold and silver ores; and (7) what current density at the anode and at the cathode is most suitable for the regeneration of cyanide leaching solutions which contain ferrocyanide and sulphocyanide.

Conclusions.

A summary of the results of the experiments on the electrolysis of cyanide solutions is as follows:

1. The electrolysis of cyanide solutions by direct current and by means of insoluble anodes is accompanied by progressive consumption of cyanide, which is the result of oxidation of the cyanide to oxy-cyanide compounds.

2. Anodes of metallic iron, nickel, and lead are dissolved during the electrolysis of cyanide solutions; these metals on entering the solution are immediately precipitated, the lead as hydroxide, and the iron and nickel as a mixture of hydroxide and cyanogen compounds. The consumption of cyanide by means of these anodes was relatively greater the lower the current density, as at high current density oxygen was simultaneously liberated, and consequently less metal was dissolved. The consumption of cyanide was less in case of the lead anodes than with either the iron or the nickel.

3. Peroxidized lead and 'passive' iron anodes were found to be more permanent than metallic anodes of either iron, nickel or lead. There was no apparent corrosion of either the peroxidized lead or the passive iron anodes so long as they kept continuously in use, but exposure to the atmosphere for several days destroyed their permanency, due to spontaneous oxidation. The passive iron anodes were found to be more satisfactory than peroxidized lead anodes for electrolyzing cyanide solutions, in that the cyanide consumption was much less and the voltage was slightly less in most cases.

4. Electrolysis of cyanide solutions which were used for leaching a special refractory gold and silver ore containing sulphide minerals was found not to be beneficial either in reducing the cyanide consumption or increasing the percentage of extraction.

5. Low current density at both the anode and the cathode gave less consumption of cyanide, and in several cases seemed to have produced a slight amount of active solvents, but not enough to compensate for the loss of cyanide which resulted by the electrolysis.

6. The cyanide consumption during electrolysis of cyanide solutions was greater when the current

density at the cathode was run higher than at the anode, which suggested that the loss of cyanide is the result of oxidation, with the formation of oxy-cyanogen compounds. The lower the current density at the anode and the higher it is at the cathode, relatively greater is the cyanide consumption.

7. When cyanide solutions containing sulphocyanides or ferrocyanides are electrolyzed, the cyanide consumption was much less than that which occurred in pure cyanide solutions, which indicates that sulphocyanide and ferrocyanide act as protective agents during the electrolysis of cyanide solutions.

8. The increased alkalinity of cyanide solutions reduced the cyanide consumption during electrolysis, due to increasing the conductivity of the solution. The higher the voltage the greater the cyanide consumption, and vice versa.

9. The electrolysis of cyanide leaching solutions had no apparent effect upon reducing the time required for treating a refractory ore nor in increasing the percentage of extraction.

10. Peroxidized lead anodes and passive iron anodes are corroded in cyanide electrolytes which contain sulphocyanide, if the electrolysis is conducted at high current density. No apparent corrosion occurred when a low current density (below 3 amperes per square foot, or 32 amperes per square meter) was used.

11. Passive iron anodes are more satisfactory than peroxidized lead anodes for the electrolysis of cyanide solutions which contain either sulphocyanides or ferrocyanides, in that by their use the cyanide consumption is very much less and the voltage slightly less. The lower the current density the smaller the consumption.

12. The regeneration of cyanide solutions which contain sulphocyanide and ferrocyanide does not occur by electrolysis with direct current, whether the conditions of electrolysis be made oxidizing or reducing by varying the relative current densities at the anode and the cathode.

The suggestions which were stimulated by the foregoing experiments will form the basis of a series of future experiments, which it is hoped will contribute something more to the knowledge of what occurs during the electrolysis of cyanide solutions.

Electric smelting of tin ore has been tried in Cornwall by the Grondal-Kjellin company of London. The results were favorable, according to the *Revue Industrielle*, pure ores giving metal of 98% purity, while Bolivian ores containing 49.5% of tin and about 15% of iron yielded metal of 92% to 97% purity, which could be further refined to 99.75% or more by blowing air through the molten mass. The energy consumed amounted to 1700-kw. hours per ton on the average. By working with two furnaces, one to treat the rich slag and the other to produce the metal, the company hopes to reduce this consumption to 1400-kw. hours, giving an efficiency of 55%. There is a saving of 25% of labor. It is stated that at mines where hydro-electric power is available, the process will be commercially practicable and economical.

Coal output of India in 1912 was 14,044,360 tons.

California Oil Production for 1913

By J. H. G. WOLF

The accompanying graph shows briefly the status and the late trend of the state's crude petroleum business. With the expansion in area of the known oilfields, the production has increased, with a corresponding increase of consumption. The shipments, which are the basis for defining consumption, include all movements of oil from the fields, as well as the wastage and losses, though probably do not account for the whole of the evaporation and shrink-

been under some restraint, owing to low prices to the producer and other causes, and that the bringing in of occasional heavy-flowing wells is still characteristic of the Midway field, it appears that the production of the fields as a whole has been brought under normal control. The surplus or stock in trade for the conduct of the business is practically constant at 48,000,000 bbl., or a six months supply. The yield for August was greater than for July, owing to the bringing in of an uncontrolled flowing well of 20,000 bbl. in the Midway. September may show some further increase from this cause. With the August yield, California's production is at the

CHART SHOWING PRODUCTION AND STOCKS OF CALIFORNIA OIL.

age losses of the oil in storage, which are known to be heavy.

The features of particular importance are:

1. That the accumulation of oil in storage, or the surplus on hand, has failed to increase sensibly in quantity above 48,000,000 bbl. since about January 1, 1913.

2. That the production in a single month passed 8,000,000 bbl. in July 1913, and the rate of increase in the 24 previous months was practically constant at 54,000 bbl. per month, or 1800 bbl. per day.

3. That the consumption in a single month passed 7,800,000 bbl., in July 1913. The rate of increase in consumption in the 24 previous months was practically constant at 100,000 bbl. per month, or 3290 bbl. per day, or exceeding the gain in production by 46,000 bbl. per month.

While it cannot be denied that the output has

rate of 100,000,000 bbl. annually, as compared with the 125,000,000 bbl. produced annually by the remainder of the oilfields of the United States.

An index of the stability of the business in this state can be seen in the uniformity of the rate of increase in both production and consumption. The exploitation of new oilfields in any part of the world is attended usually by violent fluctuations in the output. This is particularly true in districts where the oil is in light and non-important measures, and which are opened and exhausted in a comparatively few years. Such a condition does not exist here.

All the prominent oil-producing fields of California have been under development for twelve years, and none has been exhausted. The gain and yield has been a remarkably uniform one, and the market has expanded correspondingly. It would seem that he who founds an industry upon the expectation of

obtaining a steady and reliable supply of crude petroleum in this state can do so with the reasonable assurance that the supply will not fail him in his generation. In a situation where suitable steaming coal is scarce, as it is on the western coast of America, the market for crude petroleum as liquid fuel is sure to be a broad and an expanding one, and with the steady decline of the Eastern fields which produce the good grades of refining oils, the incentive to prospect more widely in this state, and for years to come, will not be lacking. Of late the proportion of the output that is above 21°B., and classed locally as refining oil, has been brought to above 40%; practically all the 'flush' production of today is from flowing wells of oil above 24°B. It is said that 1½% only of the state's production is above 21° Baumé.

The data on the number of wells completed, active, and idle confirm the statement that the output is under restraint. The number of active producing wells on June 30, 1912 (omitting the 537 wells of the Los Angeles City and the Summerland wells, which for practical purposes can be considered as spent wells) was 5091, whereas on June 30, 1913, it was 5422, or a gain of 331 wells, or 6.5%. If the assumption that in oil production it requires new drilling to the extent of 10% per year to maintain a constant output in the statement of a normal condition, then a gain of 650,000 bbl. in output in one year with but 6.5% added to the number of wells producing, shows unmistakably that the fields are capable of still greater expansion, which is a gratifying situation for the industry, even though it may make hard times for the individual producer for the time being.

Sampling Coal Mines

In taking a sample of coal for analysis a geologist of the U. S. Geol. Survey is instructed to make every endeavor to procure fresh unweathered material. He is supposed to face up the bed in the mine or prospect until fresh material is available, and then to obtain his sample by making a uniform cut across the bed from roof to floor, including all such benches and partings as an experienced and careful miner would include in commercial coal and throwing out such impurities as would certainly be excluded in practical operation. He is supposed to cut sufficient coal to give at least 6 pounds per foot of coal bed sampled. The sample is hastily pulverized in the mine until it will pass through a ½-inch mesh, and then is quartered down until 4 pounds remain. This is placed in a galvanized-iron can, sealed with adhesive tape or paraffin, and mailed to the laboratory for analysis. The sampling is done on the principle that a coal mine should be sampled as carefully as a gold mine, and that the sample should be even more carefully handled after it has been taken. The object of sealing is to prevent change in the moisture content, so that the coal may reach the laboratory in practically the same condition that it exists in the mine.

The Minerals Separation & De Bavay's Processes Australia Proprietary, Ltd., has declared an interim dividend at the rate of 10% per annum.

Tube-Mill Calculations

The rate of revolution most satisfactory in practice is found to be 200 divided by the square root of D, where D = diameter in inches. Thus, a 4 ft. 1 in. mill should revolve at $200 \div 7$ (square root of 49 is 7) = 29 = the correct number of revolutions per minute (Davidsen).

The correct change of flints is found to be $W = 44 \times N$, where W = weight of flints required and N = the number of cubic feet contained in cylinder of tube-mill; but West Australian wet-grinding practice takes nearly 50% more flints than these figures, and South African practice is even higher.

Ball's investigation shows that most efficient pebble load is about seven-sixteenths of the volume of the tube-mill. The most effectual crushing load is three-fifths of the volume, which corresponds to Rand practice, but this is gained at too great an expense for power.

Ball's tests indicate the most efficient figure to be 30 tons per one ton of pebble charge; output 10 tons of ground sand per ton of pebble charge, or 1½ tons per horsepower (African practice at 90-mesh). El Oro output shows 1.2 tons per horsepower at 150 to 200-mesh. Various observers show that the percentage of moisture should not exceed 38.5 to 39 per cent.

Nothing has yet been published which would prove that it is economical to feed particles coarser than 10 to 14 mesh. Three-mesh has been much used in South Africa, but the investigations of the introducers of the tube-mill are not in favor of such coarse feed.

For wet crushing, large pebbles of 3 to 4 inches in diameter are employed, but some of the most accurate observers prefer a rather smaller pebble than this, as in dry crushing.

In testing efficiencies and outputs of tube-mills, samples obtained during the first hour after an adjustment should be regarded as abnormal.

The value of the gold and silver bullion production in Salvador, Central America, in 1912 amounted to \$1,396,730, as compared with \$1,525,998 for the previous year. The Butters Salvador Mines Co. continued to be the most important producer. A new company, known as the Monte Mayor Gold & Silver Mining Co., started operations during the year. The Comaraean Gold Mining Co., at one time a large producer and at present not running at full capacity, intends to install new equipment soon. The other mines now in active operation are Los Encuentros and El Tobanco. Practically all the bullion and ore are shipped to the United States.

The Spassky and Atbasar copper properties, in Siberia, are to be operated by one company, although they are 300 miles apart. The ore reserves in the Atbasar are 517,909 tons of 10.25% copper, and a smelter is to be erected. The Spassky produces over 400 tons of copper monthly, while the company owns a coal mine with large quantities of good coal. The capital of the Spassky Copper Co. is to be increased to £1,250,000.

Russian Platinum

Owing to the steady advance in the price of platinum which has been taking place for a number of years, and the new uses which are being found for the metal, the platinum industry of the Urals, which is the most important producing district of the world, is experiencing an awakening both as to methods and scope of operation. An imperial law was passed some time ago whereby the exportation of crude platinum, after a date to be fixed by the Minister of Trade and Industry, would be prohibited. The object of such a measure was evidently that the government might exercise, in part, a control of the industry. The reasons for the government exercising this limited control appear more sentimental than material, in that the small plant that will be necessary for handling the entire output will add but a few thousand rubles to the income of the Russian workmen, and the possible lack of efficiency in refining might well counterbalance the capital which will be kept in the country by this measure. However, with a general supervision exercised by the government and advances being made to the producers from the Imperial Bank, it is expected that the violent fluctuations of the market will be materially decreased. In that the consumption is almost wholly without the country and is largely controlled by syndicated interests, it is reasonable to suppose that the government may find it difficult to exert a control of the industry. Whether it will ever suit the convenience of the foreign syndicate to run the price down again will depend upon the firmness with which the government proceeds with its new policy of holding the platinum industry both as a producing and manufacturing industry in the country itself.

Expansion of Mining Operations

At the present time the high price of platinum is attracting labor from the goldfields of Russia and every piece of available ground is being worked according to the means of the operator. The tendency toward the industry coming into the hands of companies capable of operating on a large scale, and the business is gradually passing into the hands of the large operators. Among these companies may be mentioned the Ovsyankin company, which is a purely Russian organization controlling 109 placers in the Orenburg government. Counsellor Ratkoff-Rashnoff has formed a company with a capital of 10,000,000 rubles, known as the Lower Tagil Platinum and Mining Company, which will operate in the Perm government. Another company has been formed to work platinum deposits in the Lower Tagil district belonging to the Demidoff successors and Prince San Donato. The passing of the control of the platinum fields into the hands of the larger operators is the natural sequence, in that the deposits have become of lower grade and it has become necessary to handle large quantities of material, requiring more expen-

sive equipment and larger capital to work them.

The illustration presents a type of the mill which is gradually becoming extinct. It is from such plants that the bulk of the world's output has been produced in the past. On the right of the picture is shown the 'stirrer' and trommel into which the gravel is dumped and screened, from which it passes to the tables, which are housed in the low shed in the centre of the illustration. In this particular mill there are three tables. The tailing is removed through the revolving cylinder, shown at the left of the illustration. This cylinder is fitted with an archimedean screw which acts as an elevator and dumps and stacks the tailing. The platinum is recovered in the form of small nuggets, scales, and rounded or irregular grains. The specific gravity of this concentrate is from 14 to 19 and the percentage of metal varies from 70 to 85. The method of work-

PLATINUM MILL IN THE URALS.

ing the platinum alluvial deposits was described in the *Mining and Scientific Press* of June 22, 1912.

The scope of the industry in the Perm government may be had from a recent report of the Perm Government Gold and Platinum Council. It is stated in this report that the average annual production of platinum from 1903 to 1912 amounted to 330 poods and 29 funts (191,254 oz.) Just at the present time the market at Ekaterinburg is reported as weaker. The price which has obtained for a long time of 9 rubles 90 kopeks (\$5.04) per zolotnik (0.13715 Troy oz.) has declined to 9 rubles 40 kopeks (\$4.80). As a result little if any business is being done at the price named and the stock of platinum has increased somewhat. At the present time the output is being consumed largely in the manufacture of laboratory equipment, the sulphuric acid industry, photography, dentistry, electrical apparatus, jewelry, and in the manufacture of lamps.

Gold production of British Guiana in July was valued at \$739,780, and 2558 carats of diamonds \$13,983 were won. July output of gold in West Africa was 32,345 oz., Rhodesia £249,302, and Queensland £107,050. In August the Transvaal produced 728,096 oz., Western Australia 110,169 oz., Victoria £175,100, New South Wales £156,348, and New Zealand £156,348.

Tin-concentrate output of Nigeria in August was 390 tons from 31 companies.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Solution Control in Cyanidation

The Editor:

Sir—A. W. Allens' article in your issue of September 20 calls for a protest, in as much as it implies that cyanide operators in general have been working in the dark as regards free cyanide content of working solutions. I admit that such conditions do exist, but they are by no means general. Most working solutions permit of the simple determination of free cyanide by direct titration with silver nitrate regardless of the alkalinity, a method, I believe, in general use. This method depends on the presence of zinc, which acts as an indicator, and in addition the solution must be perfectly clear, as well as the flask in which the titration is made. The end point is indicated by a very delicate opalescence best seen in strong reflected light.

The above method will indicate regeneration of free cyanide by addition of lime under certain conditions, and will also indicate decrease in free cyanide during precipitation, in contradistinction of Mr. Allens' experiences but in accord with the principles of chemistry.

Owing to complexity of working solutions there is room for argument as to what reactions occur under certain conditions, as the chemistry of the cyanide process is anything but an exact science, but it is sufficiently well understood for its intelligent application, so that the well informed operator can usually determine free cyanide with more certainty and almost as simply as one whom I knew to determine alkalinity by feeling with his fingers.

I am inclined to believe that Mr. Allen overrates the evils of zinc in solution. Never in twelve years' operations have I thrown away a ton of solution on account of fouling with zinc, nor have I experienced any difficulty with either solution or precipitation of the precious metals on this account. I refer to zinc entering the solution through precipitation by this element. Such troubles are usually due to insufficient free cyanide, which has been allowed to fall below normal on account of some new condition interfering with standard titrations.

Referring to Mr. Allens' article, page 449, he says: "Routine titrations for cyanide strength had been made regularly and showed no material alteration * * *." Farther on he adds: "The solution was analyzed and was found to contain a high zinc content and also a considerable amount of copper." It is quite evident that free cyanide must have been very low. On the addition of more cyanide to solution entering zinc-boxes "the outgoing solution showed an immediate drop."

I cannot accept Mr. Allens' statement in regard to function of hydrogen in precipitation. The liberation of hydrogen is sometimes incidental to and not the cause of precipitation. Pure zinc dissolves very

slowly in a solution of pure cyanide. It however dissolves quite readily in a solution of caustic alkali, and the action often seen in zinc-boxes is due more to alkali than to cyanide. It appears to me that the solutions in question were saturated with zinc to the extent of having all of the cyanide combined, and in this sense only. Free cyanide is the most essential condition for good precipitation. I have seen violent action in boxes, due to caustic alkali and poor precipitation resulting; also very good precipitation without any visible liberation of hydrogen.

JAMES S. COLBATH.

Los Angeles, September 30, 1913.

Prospecting by the Government

The Editor:

Sir—Mr. Albert Burch's recent suggestion for government aided prospecting was read by me with much interest, and I must say with as much trepidation as interest, for Mr. Burch's commanding position in the mining world gives to his conclusions a force that makes such socialistic suggestions the more to be feared. To Mr. Burch's invitation for criticism I was glad to see that the first response—that of Mr. R. P. McLaughlin—took the individualistic standpoint.

Mr. Burch's argument in brief is that the easy mines have been found, and that prospecting, through a continually lessening likelihood of reward, seems in danger of being abandoned as an occupation unless stimulated by the certainty of a salary, and this he would have the government pay.

Theoretically Mr. Burch's assumption of lessening likelihood of reward seems to be true: for by just the number of mines discovered in the last forty years there are so many deposits eliminated from the possibility of discovery. But this is offset in a great measure by the constantly increasing factors which redound to the prospector's advantage. Among them, security from Indian attacks, greater and quicker facilities for transportation, supplies comparatively near at hand, perfection of metallurgical processes which make refractory and low-grade ores—valueless in the past—of great value now, readily obtainable geological reports eliminating at once vast areas which have no possibility of bearing precious minerals, and the unquestionably greater ease with which capital can be obtained for the development or purchase of a promising prospect.

When Scheffelin packed his burros and started across Arizona on the trip which was to end in the discovery of Tombstone he, like Theseus who faced the whole world armed only with his club, trusted to his valor. The factors for failure confronting him were greater, I think, than those confronting the prospector of today. He faced the very great danger of death from Indians; he was cut off from the possibility of supplies; and he traversed an uncharted desert where now every water-hole is mapped and known. He also crossed areas of country whose mineral possibilities, or lack of possibilities, he himself had to determine, instead of being able to go through a process of elimination by consulting the geological reports which now are to be had by anyone for the asking.

Yet in spite of all these obstacles Scheffelin succeeded. He was only one out of many men of his time to do so, however. The great majority of his contemporaries did not succeed. It is inherent in the nature of the game then as now that no matter how many are called but few are chosen. But there were then, and there are now, and always will be, men whose psychology is such that they will bet their lives on a big reward but find it impossible to play them for the smaller, if more certain, gains of plodding industry.

That heretofore prospected regions even though mined in for years still offer chances for the careful or lucky prospector is seen from the comparatively recent discoveries of Tonopah and Goldfield in sight of the old camps of Montezuma and Candelaria. And there are numerous such instances.

The prospector of the future must be a more painstaking and a more scientifically trained man. He must rake the region he prospects with a fine-toothed comb instead of running over it. But at bottom he will still be the man who prefers the great gamble to the drudgery of detail. A few will achieve glittering success, while the majority will eke out a living one way or another, which is what the majority in every pursuit has always done and always will do whether aided by government or not.

If unaided I believe a keener and more efficient man will result. But supposing that Mr. Burch's suggestion is carried into effect and every western state sees its government prospectors take the field, who will profit by it? Undoubtedly a large number of men will become pensioners and sure of a livelihood whether they honestly try, or fortunately succeed, or not, and another bureaucracy of politicians will have been installed to administer this function of government and deal out the plums.

The ultimate and great reward will go to the capitalists, then as now, who have the means to develop and equip the properties. It will not result even in so democratizing mining that all capitalists will have a chance at the government paid for discoveries, but only a small group of capitalists—those who know the mining game. That is as it is now.

Mr. McLaughlin has, to my mind, clearly and completely defined the kind of work that should be undertaken by the federal government: "that which is so large or upon which returns will be so long delayed that private enterprise can not well embark; or work which so intimately affects the common welfare that private enterprise can not be entrusted to do it."

It is not the function of a government like ours to subsidize or bolster up an industry in its time of depression. And if it is asked to extend a paternal hand to one wailing child it must be equally considerate of all others who complain.

A few years ago a considerable number of citizens were crying "we must do something for silver." Tomorrow it is the prospector who must be assisted; and the day after the cowboy, and grain grower, the horse breeder, and all through the list until it may be there would be no limit to those looking for assistance.

Before giving our support to government aided

prospecting let us pause long enough to carefully consider what is being proposed. It is well to get clearly in our minds who and what government is in this country, since it is becoming so common to call upon it for and expect its assistance. This government is not an omnipotent entity with unlimited means to do. It is, to quote a well known economist, merely "all of us." And to ask the government to assist an industry or pension a class it is but demanding to know "what shall all of us do for some of us." This is not the fundamental of Anglo-Saxon genius; it is not that which has made this country great.

MARSHALL BOND.

Seattle, Wash., Sept. 27.

Mining Experts and 'Practical' Men

The Editor: .

Sir—It seems that one should always be prepared for surprises in mining. New modes of occurrence of the various metals are continually described, and the wisest old prospector will shake his head and say: "You never can tell nowadays; you find valuable metals most anywhere." In the course of my travels through Arizona, I met with a rather pathetic case, which I think illustrates this point. An old Comstock miner had located a group of claims and for a number of years had quite religiously done the required assessment work. I was induced to visit his ground, as I was given to understand there were some very good copper showings. Upon arriving at the property, I found the old prospector a very entertaining and cordial fellow, and after a little visit started with him over the property. I could see at the outset that it meant some pretty stiff climbing, and I had some misgivings as to the ability of my companion to hold out. Later in the day I was quite disabused of this opinion, and, indeed, I was more than surprised to see the agility and ease with which this man of 65 could get over the ground. A wonderful commentary on the healthfulness of outdoor life. But, to go back to the point: I had walked some distance, and as yet had seen no favorable outcrop, and was beginning to get a little anxious, though I said nothing. Finally, my companion stopped and, picking up some rock, said: "There, don't you think that looks pretty good for copper?" To say that I was surprised is putting it mildly. I did not know how to answer. To be sure, the rock was green, but I did not suppose anyone would call it copper. If it had been anyone else I would have laughed outright and considered it a joke, but instead I looked wise and deliberately taking out my glass, examined the rock closely. I found it to be a dioritic type, containing considerable chlorite. "You do not expect to find copper in this rock, do you?" I said. "Well," he answered, "I sent a specimen away to a university, and they told me it contained copper." I do not know what kind of an analysis they could have given the old man, but evidently it was so involved in technicalities that it led him to believe that this rock should contain disseminated copper. It only goes to show that a little expert opinion couched in technical language is often a dangerous thing. Just a plain, straightforward statement would have given

no misunderstanding of the rock's composition.

I found the old gentleman had driven a 530-ft. adit, almost unaided. The only indication of mineralization was the occurrence in a few seams and small fissures, of primary chalcopyrite. I found certain places where, for a considerable distance, the whole rock would average about 0.5% copper. However, there was no evidence of leaching or secondary enrichment. In other words, there was absolutely nothing to warrant exploitation. The peculiar thing about this experience was that I found some adjoining ground (to which he took me last, and which he did not consider important) that contained some excellent surface showings. The rock was soft and well leached, and in certain places I found rich masses of copper carbonates and oxides. As you will imagine, I could not understand why the work had not been done in this locality. I was decidedly reluctant to criticize, but I made quite plain my opinion of the situation, and I hope it did some good.

Another experience of quite a different sort illustrates how people will take liberties with nature in exploiting properties. My attention was called to certain clay deposits in Texas, which were said to be rich in copper. The matter was put up in such a way that it seemed worthy of investigation, so accordingly I made a trip to the locality. I found a region occupied by red sandstones and red and blue clay, interstratified in certain places with gypsum and salt. A number of shallow pits had been dug, none of them deeper than 15 ft., and in most of these I could find concretions of copper. In some instances the surface leaching had given a perceptible copper color to the banks, the whole constituting a rather interesting occurrence of copper, but decidedly discouraging from a commercial standpoint.

With no attending circumstances this might be passed off as one of those useless but entertaining side trips which frequently find their way into the itinerary, but the locality had been 'wildly' exploited by a Dr. ———, who (as he told the local people) had had years of experience in mining in Colorado. He led them to believe that they had here a wonderful deposit of copper which only needed capital for development. He promised them big profits if they would only back his plans. In consequence the neighborhood was much excited. In support of his position he had written a very elaborate report, which had gained a wide local circulation and evidently made a deep impression. In fact, I was reminded a number of times of the "scientific standing" of the doctor. I was really very glad to obtain a copy of this report, as it has the advantage over so many of being decidedly entertaining and amusing. There are no tedious or involved sentences to wade through. I take the liberty to give a few excerpts:

"This clay formation, running in depth from 3 to 50 ft., carries from 3½% to 66% of copper, with a uniform amount of from \$4 to \$5 in gold and silver. It is self-fluxing, being easily run in a blacksmith's forge, as the many tests have proved made here in the shop of Mr. P., who was very accommodating in the matter, being willing to interrupt his business for the sake of science and the general enlighten-

ment of the people, for which we are very thankful. The copper in the clay goes into solutions in 1 in 100% bath, going easily. The clay contains small flakes of chalcocite all through. When air touches it it turns characteristically blue and green. The chalcocite is heavy, and concentrates well with small amounts of water. The best plan would be to crush the low-grade clay in an ordinary clay crusher, concentrate and leach the rest. Experimentally, this is working satisfactorily. * * * The immense area of the field, nature being so lavish in her gifts, and the uniformity of deposit, will justify a ten-ton smelter plant to commence with. * * * The sulphide chalcocite seems the first mineral formed from the copper solution, and the azurite next, or, rather, the azurite is first step of decomposition of the chalcocite. Over 150 distinct occurrences have so far been examined, and I have been able to draw some very keen inferences. Some of the clay gives averages of from 3.5 to 30% copper, by actual smelter tests. * * * There is no doubt but that what is already exposed would run a smelter the size we propose to build, for many months, and I predict a brilliant future for all those who take advantage in time. Another matter of easy solution would be the building of the long contemplated dam across Cottonwood, with the slag and gang from the smelter, and reduction plants, not only building the dam without any expense, but furnishing a dump for the waste material from the plant."

Evidently these experiences teach a moral, but I hardly think it necessary for me to point it. Perhaps these occurrences will help to justify the position of the much abused and criticised expert and consulting engineer. I hope, Mr. Prospector and Mr. Practical Superintendent, that you will concede that there is a legitimate place for us in the general scheme of things.

FRED B. ELY.

Salt Lake City, Sept. 13.

Mineral Production of Northern Russia

In the Murman district of northern Russia are considerable mineral deposits, particularly on the coast line, but few mining men have done any exploration there. Gold placers have been found on the Rimbach peninsula, and gold-bearing veins on the River Titovka; but Russians have evidently not bothered with them. An engineer named Popovitch did some prospecting at Murman in the lead deposits, but these are now abandoned. Coal has been found and there are said to be large deposits of manganese.

Gold production of the mines at Kolar, India, during August, was as follows:

	Tons.	Value.
Balaghat	3,600	\$ 25,200
Champion Reef	18,575	200,000
Mysore	25,767	345,000
Nundydroog	7,500	120,000
Ooregum	12,892	144,000

The Colorado State Geological Survey at Denver has for sale at low prices interesting reports, bulletins, and topographic geologic maps of various districts of the state.

Special Correspondence

LONDON

COPPER IN CENTRAL AFRICA, AND THE BWANA M'KUBWA MINES.

The development of copper deposits in Central Africa has provided much scope for speculation on the London Stock Exchange. The enterprise of Robert William, in connection with the Katanga copper ores is already well known to your readers, as several American engineers have been on the spot and have published their impressions. Another deposit not far south, just over the border in Northern Rhodesia, has attracted nearly as much attention in England. This is the Bwana M'Kubwa, a property owned by a company belonging to Edmund Davis' group. Mr. Davis is at present the leading 'promoter' in London. You never know where he will break out next, and you do not always know that he is at the bottom of some of his promotions. It is not surprising, therefore, that the chief attention in connection with Bwana M'Kubwa has been centred on Stock Exchange operations and not on the development of the deposit and the study of the metallurgical problem. Shareholders and the public were kept in the dark, and a technical journalist like myself could never elicit any information or induce an answer to specific questions, if a visit of inquiry was made to the office. S. J. Speak, of the firm of Hooper, Speak & Co., has recently made an examination, and his report has been published. This report contains the first intelligible account of the ore deposit, but unfortunately it leaves us 'no forader', as the Yorkshireman says, as regards the method of treatment of the ore. I quote briefly some of the facts to be extracted from Mr. Speak's report.

The mine is 491 miles by rail north of the Victoria Falls. At present the nearest port is Beira, 1448 miles away. The railway connection is circuitous, and economic conditions would be improved if a connecting railway could be built from Rhodesia Broken Hill to join the Lomagundi railway at the Eldorado mine and thus give a more direct access to Salisbury and the Beira railway. A stony ridge or *kopje*, 2400 ft. long, rising from a level plain, marks the outcrop. The deposit consists of a central rich ore-body dipping nearly vertically, 1800 ft. long at the 100-ft. level and averaging 4 ft. thick, and orebodies on each side of lower grade and measuring 30 to 60 ft. thick. Five vertical shafts have been commenced in the hanging wall of the central orebody; one of them was sunk to 528 ft. when excessive water prevented further exploration at depth. The 100 and 250-ft. levels are about 1800 ft. long, the 350-ft. level 357 ft. long, and the 450-ft. level 95 ft. long. Cross-cuts have been driven into the hanging wall and foot-wall at intervals. The central orebody is friable and porous, and consists largely of silica and carbonate of copper. Its specific gravity in place is only 1.25, and this unusually low figure accounts for previous errors in the estimates of tonnage. Below the 350-ft. level it changes abruptly into silicious dolomite, and the copper content diminishes, occurring then partly as carbonate and partly as bornite and chalcocite. The amount of rich ore is estimated at approximately 50,000 tons, averaging 12% copper. The carbonate is not evenly distributed, but occurs as small bands up to 4 in. thick. The hanging wall consists of quartzite and the average thickness is 35 ft. assaying 4% copper. There is no true foot-wall. The orebody merges into 4 to 10 ft. of decomposed rock carrying little copper, and beyond this is quartzite averaging 60 ft. thick and 4% copper. These two quartzite orebodies are extensive, and 800,000 tons is proved above the No. 2 level. The copper minerals in the quartzite are two-thirds bornite and chalcocite, and the other third carbonate. Mr. Speak is of opinion that the central orebody was originally a bed of dolomite, and that the copper was introduced from the surrounding quartzite by surface waters, the acid of which removed most of the lime and magnesia. An examination of the quartzite without the microscope indicates that the quartzites were sedimentary rocks, probably dolomitic sandstone, which were silicified at the time their copper content was introduced.

Very little iron is present in the ore. No granite or other igneous rock has as yet been discovered in the neighborhood. The surface of the country is so thickly covered with soil that geological study is difficult.

The report is a satisfactory one from the engineer's point of view, but the part dealing with the metallurgical problem is not so convincing. Up to the present, the only work done has been to produce a concentrate on jigs and tables from the carbonate ore and to leach this by the Siemens-Halske process, which involves dissolution in sulphuric acid and the precipitation of copper electrolytically. In practice, a concentrate averaging 37% copper was obtained, and this concentrate contained about 40% of the copper in the ore. The leaching process was supposed to be a success in London on a small lot of ore, but it has not been put into action at the mine. Mr. Speak says that the quartzite ore presents a difficulty in water-concentration and talks of flotation processes. He is unable to provide the directors with their chief requirement, namely, a process that will give immediate profits. The board has decided to send Thomas Huntington, one of their number, to the mine to see if he can evolve a suitable treatment. Mr. Huntington is known for his work in conjunction with Ferdinand Heberlein in connec-

MAP OF BELGIAN CONGO, WEST AFRICA, SHOWING MINES AND TRANSPORTATION LINES.

tion with the sintering of lead ores. He is an American and has spent most of his active life in Italy. At present he is an adviser to the Metallurgische Gesellschaft. For myself I should recommend the directors to secure the services of an engineer acquainted with old Arizona practice and with the concentration of disseminated copper ores.

NEW YORK

THE AJO COPPER PROPERTY IN ARIZONA.—MINING IN ONTARIO.—STEWART AND OHIO MINES.—LAKE SUPERIOR STRIKE SITUATION.

The most important news of the week was the announcement that the Calumet & Arizona had taken up its option on the New Cornelia property at Ajo, Arizona. All sorts of statements have been made regarding the property, and as the management usually neither confirmed nor denied them, there was ample scope for rumor. The property was under option by the General Development Co. some time ago, but after exploration by diamond-drilling the options were allowed to lapse. In 1911 the Calumet & Arizona company became interested, and has done much more diamond drilling. It is reported that 29,000,000 tons of ore, ranging from 1.7 to 2.2% copper, has been proved, but no official statement has yet appeared. The property is about 40 miles south of Gila, on the Southern Pacific railway, and surveys will be made for a branch line, but it is much more probable that the El Paso & Southwestern will be extended from Tucson 80 miles west to Ajo. The El Paso & Southwestern, which is owned by the Phelps-Dodge interests, now has its western terminus at

Tucson, and it can readily be imagined that not much through freight from and to Pacific Coast points now gets routed over the line. With a western terminus at San Diego, or some similar point in southern California, the road would be in a much better position. But to return to the Ajo property, it is also of interest because it is proposed to extract the copper from the ore by hydrometallurgical processes, and Stuart Croasdale, with a corps of assistants, has been at work developing a satisfactory process. The original ideas, which have been widely discussed, have evidently been considerably modified in the course of experimental work. The ore occurs at the surface and will be mined by steam-shovels in the way that is now becoming common practice. The ore for 50 to 75 ft. in depth is oxidized and well adapted to leaching. At greater depth it is succeeded by sulphide ore, and the method of treatment for that will be solved later.

Ontario is making a better showing each year in its returns of mineral output. The total for the first half of 1913 was \$18,598,000, an increase of 20% over the first half of 1912. Silver alone showed a slight falling off, while gold was responsible for one-half of the increase. Nickel production amounted to 12,104 tons, valued at \$2,514,414. A new producer in a new district is the Alexo mine, near Porcupine, which is shipping to the Mond smelter at Coniston. The big new nickel company is temporarily held up to wait more auspicious money markets before attempting to finance its operations. The iron industry of the province is showing a gratifying growth, having quadrupled in the past decade. In this connection, it may be remarked that T. J. Drummond has resigned the presidency of the Lake Superior corporation and was succeeded by J. F. Taylor, of Sault Ste. Marie. In reporting on the operations of the Algoma Steel Corporation, its most important subsidiary, Mr. Taylor announced that over \$26,000,000 has been spent in extensions and improvements in the past four years. The rail mills have been increased to 1200 tons daily capacity, the blast-furnace plant has been enlarged, coke-ovens have been built, and new open-hearth furnaces as well. The Company has an exceptionally good power-plant.

Much has been made over the loss of control which F. Augustus Heinze suffered at the meeting of the Stewart Mining Co., held in Kellogg, on September 29. Mr. Beaudry is the superintendent of the mine, and is regarded as Mr. Heinze's representative. However, the board represents the John W. McKinnon interests, and as McKinnon and Heinze are friendly, the latter is only removed from the active headship and not from practical control. John W. McKinnon is vice-president of the Assets Realization Co., which was formed to clean-up the wreck of the United Copper Co. Now that he is out of the control of Ohio Copper, Mr. Heinze is practically divorced from the mining field, but he is still supposed to have large land holdings in British Columbia. The management of the Ohio Copper Co. is struggling with the problem of how to make the mine pay. The ore only runs about 1% copper, so that even if the present poor recovery is improved by the flotation experiments, there is still not much margin to work on. Much has been said about the charge of 15c. per ton for transportation of the ore to the mill through the Mascot adit. In proportion to the cost of mining, this is undoubtedly high, but the company which owns the adit protests that it cannot meet its operating costs at a less figure. Under the circumstances, the natural thing to do would be to merge the two companies, since neither can make any money unless the other operates.

Some well known names have been figuring in print recently. A suit is pending in the Supreme Court of New York against Will S. Tevis, involving a payment of \$150,000 made on promissory notes to Charles W. French, in connection with surveys made for a railway from Bakersfield to the California seacoast in order to transport iron ore from mines which it was hoped to develop into big producers. Will S. Tevis, who is prominent in the Bay Cities Water Co. and a large group of affiliated Pacific Coast enterprises, is the son of Lloyd Tevis, who was an associate of J. B. Haggin, Clarence Mackay, and the group of men who were the leading figures in mining in the

'70s. The Homestake mine, in South Dakota, is still owned by the Tevis and Hearst estates. J. B. Haggin is the only one of the group still alive, and when it was reported recently that he was seriously ill at his Kentucky farm, there was great regret. Fortunately, the report proved untrue. Although over 90 years of age, Mr. Haggin is still vigorous and directs his Peruvian enterprises with keen insight.

The Lake Superior strike situation is apparently making progress toward settlement. All but two of the mines are taking out some ore, and the Calumet & Hecla is said to have 1200 men at work. However, most of the companies were short of trammers before the strike was called, and not much output can be hoped for while the strike is on. The companies absolutely refuse to have any dealings with the Western Federation, and the only possible conclusion of the difficulty involves non-recognition. When the strike was first called, the best miners largely emigrated to Butte and the iron mines, but they are reported to be coming back, so that a better grade of labor is becoming available. The strike leader on the South Range is reported to have left, and local business people are optimistic. But not much copper can be expected from the Lake country during October, and with the Washoe smelter shut down for a week, the October output promises to be small. If business generally improves, now that the tariff is finally settled, and buying of copper for domestic consumption is resumed in much volume, there can be no doubt that a sharp rise in the price of copper will result.

ST. LOUIS, MISSOURI

CONSOLIDATION OF DOE RUN AND ST. JOSEPH.—ENORMOUS CAPACITY OF NEW CONCERN.—LITIGATION SETTLED.—ST. FRANCIS LEAD COMPANY.

Announcement of the agreed plan of consolidation of the St. Joseph Lead Co. and the Doe Run Lead Co. was made October 4. Negotiations looking toward such a union of the two companies and settlement of other outstanding problems have been under way for months. The plan now put before the stockholders was formulated by a committee consisting of John F. Shepley, F. N. B. Close, C. M. Chapin, C. H. Crane, M. Kotany, E. C. Smith, and M. F. Watts, acting on the advice of J. W. Kendrick as railroad expert, and J. R. Finlay as mining engineer. Consolidation is to be effected by exchange of \$5,000,000 new stock in the St. Joseph company for the entire outstanding \$6,500,000 of Doe Run stock. As the St. Joseph company has issued \$10,000,000 in shares to its existing stockholders, this practically results in consolidation on the basis of the Doe Run owners taking one-third of the amalgamated properties. In fixing this ratio, Mr. Finlay considers that the St. Joseph Lead Co. has 6444 acres of land of the first class, that is, lands either known to contain ore or geologically so favorably situated as to carry the presumption of containing ore; and 2810 acres of the second class, that is, lands which may carry ore, but in which its occurrence is doubtful and rather improbable. The Doe Run Lead Co. has 3103 acres of first-class and 1337 acres of second-class lands, he finds, so that the St. Joseph Lead Co. has a little more than twice as much as the Doe Run of each class. He also finds that the amount of ore in sight in the lands of the St. Joseph Lead Co. may be estimated at 11,200,000 tons; that of the Doe Run Lead Co. at 8,250,000 tons. Promising and partly developed lead lands should add 11,075,000 tons to the estimate of the St. Joseph and 4,450,000 tons to the estimate of the Doe Run company, bringing the grand total for comparison up to 22,275,000 for the St. Joseph and 12,700,000 tons for the Doe Run company. The new concern will, it is evident, at once become the largest lead-mining company in existence, with an annual capacity of 70,000 to 80,000 tons of pig lead. Mr. Finlay has already been engaged as consulting engineer and will be in charge of operations. It is understood that \$1,000,000 per year of the earnings is to be devoted to extinguishment of the floating debts which led to reorganization of the companies, and that, as part of the settlement, Robert Holmes' suits against the companies and

their officers are to be dropped. Other minor points are covered by the agreement, but the essential point is that these magnificent properties are to be managed hereafter as one unit and that new men join in the management. The St. Joseph properties have not been previously valued, but Mr. Finlay's appraisal of the Doe Run is said to check closely with that made 18 months ago by Philip N. Moore and C. P. Perrin. The Doe Run, while it has less reserve land than the St. Joe, has excellent earning capacity. Additions to new mills just about ready to operate give a crushing capacity of 900,000 to 1,000,000 tons. It may be noted for comparison that the Homestake and Treadwell groups each crush about 1,500,000 tons per year. The new St. Joseph company will be prepared to handle more than 2,000,000 tons per year. Costs have not been made public, but are, presumably, about \$1 per ton, while the average grade is perhaps a little above 3 per cent.

Another of the local lead companies is threatened with litigation. S. F. Beals has applied for a receiver for the St. Francis Lead Co., the Potosi Lead Barytes & Mercantile Co., and the Potosi Miners Co., alleging juggling of stock to the disadvantage of minor shareholders. The St. Francis Lead Co. is a new concern, which, after exchange of stock in the practically bankrupt concerns that had preceded it, purchased the Jake Day tract between Flat River and Leadwood. The Company made one or two payments and then was unable to go ahead. It borrowed money from the St. Louis Smelting & Refining Co. to make one payment and so got into debt. A shaft has been sunk, a run of ore found, and about 300 tons per day, said to contain 5 or 6% lead, is being shipped to the St. Louis mill, where the ore is being treated on contract. If the ore holds out, it should be possible to complete payments, extinguish the debt, and pay dividends; but if the Company must waste money in litigation, the prospect is not hopeful. Fortunately, it is not anticipated that the action brought by Mr. Beals will prove serious.

PLATTEVILLE, WISCONSIN.

SUMMARY OF THE DISTRICT'S OPERATIONS.—ZINC ORE PRICES AND PRODUCTION.—MINES AND EQUIPMENT.

September, usually depended upon to produce record-breaking results in the Wisconsin zinc-lead field, this year fell below a normal output, although conditions generally were favorable to a large yield of mine product. Only large operating concerns, notably the New Jersey Zinc Co., Vinegar Hill Mining Co., Wisconsin Zinc Co., and Frontier & Cleveland Mining Co. did especially well. They were responsible mainly for the yield reported. Prospecting has reached a low point all over the field, which augurs disastrously for the industry as a whole, because the average zinc mine is shortlived, and unless new ground is opened for development and production, the area available for ore diminishes.

The level of ore prices was fairly well maintained throughout the month, the average for standard grades being close to \$46 per ton, basis of 60% ore. Mifflin reported sales of 55% ore at \$42 per ton; Benton, Galena, and Cuba, sales of 45% ore at \$32 per ton; Platteville, Cuba, and Galena, roasted ores at \$46 per ton; with low grades, 30 and 35% zinc ore, \$16 and \$21 per ton, respectively. Lead ore was in better demand, quotations being made freely at \$58 per ton, but shipments for the entire month were light. Shipments of sulphur ore also fell below the production reported in August, the Wilkinson mine delivering the bulk of the production shown in the table following. Production of carbonate of zinc ore received impetus by the New Jersey Zinc Co. coming into the market late in the month and bidding the ore up lively, \$21 per ton being reported on choice grades. As this commodity is mined exclusively in the upper horizons, in the dry, where pumping is obviated and little blasting is called for, the profit is greater than on the other ores. A heavy tonnage is sure to be produced this winter from the northern camps, where there is a good deal of this ore.

Sales of zinc ore during September were distributed among the following buying concerns: Mineral Point Zinc

Co., 4212 tons; Grasselli Chemical Co., Cleveland, 1398 tons; Empire Roasters, Platteville, 946 tons; National Separating Co., Cuba, 877 tons; Matthiessen & Hegeler Zinc Co., 686 tons; Illinois Zinc Co., Peru, 777 tons; American Zinc Co., 384 tons; Linden Zinc Co., 275 tons; and Joplin Separating Works, Galena, 119 tons; a total of 9674 tons. The Mineral Point Zinc Co. set the pace in bids all the month and secured almost half of the total production.

Lead shipments were made by H. Lewis, Highland, 50,000 lb.; Ross mine, Linden, 59,630 lb.; Kennedy mine, Hazel Green, 60,000 lb.; Federal mine, Day Siding, 82,000 lb.; Fox mine, Benton, 53,600 lb.; Calvert, Benton, 50,000 lb.; East End, Platteville, 60,000 lb.; Wilkinson, Benton, 81,000 lb.; Vinegar Hill, Galena, 82,000 lb.; and Northwestern, Buncombe, 64,700 lb.; a total of 642,930 lb. Shipments of sulphur ores were about evenly divided between the Grasselli Chemical Co., East Chicago, Indiana, and General Chemical Co., Hegewisch, Illinois; the former securing 2,249,640 lb. and the latter 1,948,260 lb. The Wilkinson mine at Benton was the chief contributor, with the National Separating Co. and the Linden Zinc Co. offering the remainder. Gross production of zinc concentrate from mines during the month aggregated 17,394,640 lb., and refined ores net to smelters, 12,409,440 lb. The Mineral Point Zinc Co. delivered 32 cars of roasted zinc ore to its smelters at DePue, Illinois. Less than half a million pounds of carbonate of zinc ore was shipped, although another million pounds remained in bins on a portion of which bids had been accepted.

Deliveries from the various districts were made in September as follows:

Name.	Zinc, pounds.	Lead, pounds.	Sulphur, pounds.
Benton	3,552,000	184,600	3,032,300
Platteville	2,614,000	60,000
Livingston	2,536,000
Hazel Green	2,532,000	142,000
Cuba	1,748,000	744,760
Shullsburg	1,736,000
Linden	1,552,000	59,630	345,780
Galena	1,470,000	146,700
Highland	496,000
Harker	296,000
Rewey	228,000
Mineral Point (local).....	224,000
Montfort	184,000
Dodgeville	180,000
Mineral Point Zinc Co.....	2,311,300*
Total	21,559,300	642,930	4,222,840

*Roasted ore.

The more important developments transpiring in the field in September are as follows: At Highland the New Jersey Zinc Co. remodeled its central power and milling plant and got up steam ready for double-shift service. The Mineral Point & Northern railway, feeding the northern mining camps, spent \$65,000 in track improvement, steel bridges, and concrete culverts. The Welgle mine, at Linden, became a new and steady producer; the Gribble Mining Co. developed a new zinc orebody showing a 'facing' 90 ft. wide and flat sheets a foot thick; the Mineral Point installed new rollers and engines furnishing electric power for its mines; Mifflin finished three new shafts on new ore deposits and was in the market for heavy equipment. The Klar-Piquette mine, at Platteville, paying 325% annual dividends during the past three years, and absent from the shipping list for three months, again began regular weekly deliveries; Cuba developed the Midway and Little Dick allotments, the latter taking over the mine and equipment of the Board of Trade Mining Co. Benton has three new producers, the Martin at Strawbridge for the Vinegar Hill Mining Co., Longhenry Bros., on the Spenseley, and the DuVall-Piquette by local people. From Hazel Green is reported a new discovery on Scrabble creek, and the completion of a 125-ton power and milling plant on the Lawrence, owned by the Cleveland Mining Co., which also purchased the Square Deal mining allotment of 160 acres.

General Mining News

ALASKA

NOME

Telegrams received in San Francisco from Nome state that, on October 5, a violent storm struck the town, demolishing about 500 houses, the wireless station, telegraph system, power-plant, and houses for two miles adjacent, after which a fire broke out, threatening to destroy the whole town. Damages are estimated at \$1,000,000. Winter is now setting in, and the inhabitants will be considerably

NOME.

inconvenienced. Supplies of fuel and food are being sent by steamer from Seattle.

VALDEZ

The Fidalgo-Alaska Copper Co. resumed operations during the last week in September, under the management of C. W. Harrington; having been shut down since last May. A stope is to be opened from the middle adit to develop a large orebody at a depth of 140 ft. The ore averages 7% copper. A shoot has been cut in another adit 127 ft. below the middle adit. The ore-bins have a capacity of 1200 tons.

ARIZONA

COCHISE COUNTY

The Commonwealth mill at Pearce started work on October 5. A stope 90 ft. wide has been opened on one level of the mine.

GILA COUNTY

Concrete pouring on the ore-bin foundations at the main east and west shafts of the Inspiration Consolidated has been completed. More than half the forms have been peeled off. Steel is being rapidly unloaded, and the steel workers will soon be at work erecting the bins. All form work is completed for the retaining wall at the coarse-crushing plant at the main shafts, and all machinery and tools have been moved to the crusher site. This work will progress rapidly, as the concrete-mixer will be placed between the main east and west shafts in the centre of the face of the wall and the concrete delivered by gravity. This face will be a solid concrete wall about 150 ft. long with a drop of 22 ft. The distributing tower now in use at the bins will not be necessary in pouring concrete for the wall, but it will probably be moved later to help in building some of the machinery foundations. Rapid concrete pouring continues on the retaining walls of the concentrator. Work is still under way on the crusher near the Scorpion shaft, and already work is being done on the foundations for the conveyor belt that will carry the ore from the collar of the shaft to the bin. The belt will have a drop of $1\frac{1}{4}$ in. per foot. Six hundred tons of ore will be handled at this point per day, to supply the 600

ton flotation test mill. About 200 tons of rock is being broken at the rock quarry and crushed daily.

The Old Dominion and Burro Mountain copper mining companies have signed contracts with the Minerals Separation, Ltd., and are to build test plants with a view to developing flow-sheets for flotation plants.

MOHAVE COUNTY

The Telluride Mining Co. has resumed development on its claims on the Tom Reed vein. The Black Eagle claim, in which the Tom Reed company recently opened a 12-ft. vein, mostly of high-grade ore, adjoins the Telluride claims. On the Blue Ridge claim, owned by the Telluride company, the veins form a junction with the Tom Reed vein, and Mr. McDonald, the superintendent, figures that at this point will be found a large and rich orebody. The Telluride main shaft is down 200 ft., and the work of sinking is being continued to the 300-ft. level. The shaft at the Lucknow, on Music mountain, is down 250 ft., and ore is worth \$20 per ton. Drilling is to be commenced at the Bi-metal mines, near Kingman.

YAVAPAI COUNTY

The Consolidated Arizona Smelting Co., at Humboldt, has secured a license from the Minerals Separation, Ltd., for the use of flotation, and is planning a mill. The present capacity of the plant is about 300 tons per day.

YUMA COUNTY

With the coming of cool weather, many companies and private owners of mines in the vicinity of Parker are preparing to resume operations. This is probably the hottest mining district in the world during the summer, and there is little activity during that season. All indications are that the coming winter will be the busiest in the history of this area. The better known properties in this district are the Roberts-Allen-Mavis group, Carnation, Osborne, Eagle, and O'Mara.

CALIFORNIA

BUTTE COUNTY

Three dredges at the Oroville Dredging Co.'s property at Oroville produced \$5870 during the week ended September 6. The Company's dredge at Pato, Colombia, recovered \$7350 from 14,550 cu. yd. during the second week in September.

NEVADA COUNTY

A lease has been secured on the old Blue Banks placer property at Moore's Flat by Coughlan Bros. This mine has been idle for 25 years, but produced a good deal of gold when operated. An old adit, about $1\frac{1}{2}$ miles long, is being reopened, and the Northern Water & Power Co. will probably reconstruct the old ditch which was destroyed three years ago.

PLACER COUNTY

(Special Correspondence.)—The Pacific Gold Dredging Co. has completed a 7-ft. Bucyrus-type dredge on its property near Auburn on the American river. The dredge commenced work on September 30. It is constructed along the latest and most approved lines and will have a capacity of 120,000 cu. yd. per month. A time record was made in the construction of this dredge which has never been equaled in California. The first load of lumber arrived at Auburn on July 17. The dredge was operating just 73 days later. The hull is 105 ft. long, 40 ft. wide, and 8 ft. 4 in. deep. H. C. Perring, who was for five years assistant superintendent of the dredging department of the Yukon Gold Co. at Dawson, was in charge of the construction work, with Oscar Wicks as foreman. The Pacific company is a subsidiary organization of the Yukon Gold Co., which is operating a large fleet of dredges at Dawson, Yukon Territory.

Auburn, October 1.

SISKIYOU COUNTY

(Special Correspondence.)—Several small shipments of specimen ore have been made during the past month to this city from the Homestake mine, in the Salmon River district. The quartz is free milling and comes from a shoot several inches wide. Ore of milling grade accompanies the richer material. The Homestake is chiefly owned by R. S. Taylor, of Yreka. The owners of the Osgood quartz mine, one mile west of Yreka, have purchased a 5-stamp mill and plan to have the plant in action within a few weeks. The sinking of a main shaft is under consideration. Developments have been under way for about three years, and a large reserve of milling ore is stated to be developed. William Beal is superintendent. C. L. Harris, of San Francisco, and T. T. Calvert, of Portland, Oregon, have completed arrangements for the operation of their mill on Badger creek. The mine comprises six claims, and a number of promising shoots have been opened during the four years of development. Shipments of coal from the mines near Ager are finding a ready market in Yreka, Montague, and other towns. The product is stated to be excellent for domestic purposes, and is being used in preference to wood. Several distinct seams of coal are reported in the mine. The new owners are sinking deeper and mining a better grade product than formerly. It is reported that outside capitalists have acquired the mines of the Salmon River Mining Co. Florian Le May and George Tebbe have arranged to resume work on the Sunnyside mine, in the Greenhorn creek district. A long drift will be extended to tap the back channel. The gravel was profitable when last worked.

Yreka, September 28.

TRINITY COUNTY

The auriferous gravels and gold lodes of the Weaver-ville quadrangle are described, respectively, by J. S. Diller and H. G. Ferguson in *Bulletin* 540-A, issued by the U. S. Geological Survey. The district studied embraces part of Shasta and Trinity counties and has an area of 26 by 34 miles. Redding, 52 miles from Weaverville, is the main distributing point. The La Grange and Trinity River Consolidated are the most important hydraulic properties in the Weaverville basin. The outlook for future placer mining in the region is encouraging.

Lode mining began in the quadrangle in 1852, and the total output of gold to the end of 1911 was about \$15,000,000. In that year there were 49 producing mines in the Shasta portion and 24 in the Trinity portion of the area, producing 38,193 and 14,411 oz. of gold, respectively. The principal gold deposits are fissure veins, as a rule narrow with steep dips. They are most numerous in slate, while another type exists which cuts the quartz-diorite and alaskite-porphry, especially near Whiskeytown. Basic dikes occur near them.

TUOLUMNE COUNTY

Development work at the old North Star and Black Warrior mines on Moccasin creek is being conducted uninterruptedly by the Fayalense Mining & Milling Co. The famous Eureka and Dead Horse group of mines, which of late years has been operated in a desultory way and frequently levied upon by miners for their wages, was sold recently at sheriff's sale to satisfy two judgments aggregating \$697. The sale price was \$1298, which sum included the cost. The property was bid in by the judgment holders. Besides the Eureka and Dead Horse, the Lady Washington, Golden West, Grizzly, and New Albany mines were included in the sale.

COLORADO

CLEAR CREEK COUNTY

J. W. Ballantine, engineer for the Edison milling process, has ten or twelve men at work installing the equipment at the Burleigh mill at Silver Plume.

GUNNISON COUNTY

J. L. McGruder, who has been experimenting for several years for a cheap method of reducing the complex zinc-lead ores of the Crested Butte district, has completed a small experimental plant in which he made a preliminary

test last week with satisfactory results. The plant consists of a furnace in which the crude ore is placed and subjected to sufficient heat to volatilize the lead and zinc contained therein, and the fumes are carried off into condensers.

LAKE COUNTY (LEADVILLE)

The district enters the last three months of the year in first-class physical condition, and the outlook for a brisk winter campaign is exceedingly bright. Several causes lead to this. The unwatering of the mines of Fryer hill now seems to be assured, as it is learned that fully 75% of the owners of ground have signed, and it is said the others will also help. It is understood that when the others come in there will be no difficulty in getting the necessary capital to carry the project to a successful issue. The unwatering of the upper Carbonate hill mines also looks encouraging, and those interested state that they expect to have the matter definitely settled within a few weeks.

The new company that has taken hold of the properties of the Big Four Mining Co., on Breece hill, intends to push development work 300 ft. below the present depth of the shaft, 750 ft. A large tonnage of ore continues to be sent from the Yak tunnel. The Western Mining Co. is shipping 400 tons of ore per day, which includes a fair tonnage of zinc carbonate ore. At Iron Hill, the Iron Silver, Louisville, and Belgian are making regular shipments; also from the Penn, Garbutt, and Little Jonny properties on Breece hill. Snow has fallen in the district recently.

LAS ANIMAS COUNTY

A battle was fought between coal-mine strike sympathizers and mine guards at the tent colony at Ludlow in which one guard was shot through the leg, two horses killed from under mine guards, and many houses riddled with bullets, on October 8.

OURAY COUNTY

Shipments during September from the Ouray mines were as follows: Wanakah, 580 tons; Camp Bird, 585; Atlas, 200; Barstow, 21; and Bachelor, 41 tons.

SAN MIGUEL COUNTY

The Weller Mining & Milling Co. is planning to start its mill on October 15 at its new site. The aerial tramway is also nearly completed. The Liberty Bell company is planning to construct a spur line to decrease haulage costs. The Ida Gold Mining Co. is extending the Caribbean tramway about 1500 ft. The Standard Chemical Co. is said to be mining 150 tons of carnotite ore per month in the west end of the county. The Primos Chemical Co., at Vanadium, is operating at full capacity. There is said to be great activity in mining vanadium ores in this district.

TELLER COUNTY (CRIPPLE CREEK)

The reported production of the district during September was as follows:

	Tonnage.	Av. val.	Gross val.
Golden Cycle, Colorado City....	33,000	\$20.00	\$ 660,000
Portland, Colorado City.....	10,500	22.00	231,000
Mills and smelters, Pueblo and			
Denver	3,865	65.00	251,225
Portland, Cripple Creek district.	14,600	2.96	43,216
Stratton's Independence	11,375	2.67	30,271
Colburn-Ajax	5,285	3.25	18,931
Gaylord-Dante	1,200	3.50	4,200
Kavanaugh-Jo Dandy	1,500	2.10	3,150
Rex M. & M. Co.....	700	1.40	980
Wild Horse	900	4.40	3,960
Isabella	925	3.20	2,960
Total	84,390		\$1,249,893

Details of September ore production from the various groups are approximately as follows: Gold Sovereign on Bull hill, 350 to 400 tons of \$10 to \$30 ore; Ajax property, on Battle mountain, 6811 tons, worth \$38,060; El Paso, on Beacon hill, 2600 tons; C. K. & N., on Beacon hill, 400 tons of \$20 ore; Granite property, on Battle mountain, 2250 tons; Cresson Consolidated, 5000 tons; lessees at the

United Gold property, 750 tons; and Vindicator, on Bull hill, 3250 tons, including lessees. Measurements of the flow from the Roosevelt drainage tunnel show 6280 gal. per minute. The report of the Isabella Mines Co. shows that during the past year, exclusive of lessees' work, development covered 3438 ft. Ore sales realized \$181,692; payments to lessees, freight, and transport, \$159,403; net receipts, from ore sales, \$22,288. With other revenue the total was \$26,772. Company expenditure, including mine development, was \$18,490, leaving a profit of \$8490.

IDAHO

BOISE AND CASSIA COUNTIES

Coal and lignite deposits in these counties are described by C. F. Bowen in *Bulletin* 531-H, issued by the U. S. Geological Survey. The coal at Horseshoe Bend, in the first county, is 20 miles north of Boise, on the Payette river. The total area is about 23 square miles. Both igneous and sedimentary rocks occur in the district. At most exposures the beds of coal are less than 14 in. thick, and on account of the unconsolidated character of the inclosing strata, they disintegrate rapidly. No definite statement regarding the extent of the deposits can be made, but in two places they are worthy of development. Samples from the Henry mine show 36 to 40% fixed carbon, 38 to 42% volatile matter, and 15 to 17% ash. The Goose Creek lignite deposits have an area of about 156 square miles in Cassia county, and the mineral occurs associated with the lower division of the Tertiary of the Goose Creek district in two principal beds and a number of small unimportant ones. The lower bed is the most important because of the better quality of the lignite, is from 3 to 5 ft. thick, and has been worked at the Worthington mine principally. The upper bed is from 14 in. to 9 ft. thick, but is dirty and impure. Analyses show from 21 to 32% fixed carbon, 26 to 40% volatile matter, 34% (as received from mine) moisture, and 18 to 27% sulphur.

SHOSHONE COUNTY

The Stewart mine has the third largest payroll of any of the properties operating in the Coeur d'Alene district, between 350 and 400 men being employed in the mine and mill. The adjourned annual meeting of the Stewart Mining Co. was held at Kellogg on September 28, and although not open to the press, it is stated that a compromise had been agreed to between F. A. Heinze and associates and the opposition interests. The directors elected were: F. S. Crosley, William A. Gallagher, A. D. Ormsbee, and Nash Rockwood, all of New York, and William Beaudry, of Kellogg, superintendent of the Stewart mine, who is the only one of the old directors to secure a place on the new board. Organization was affected with Crosley, president; Campbell Carrington, New York, treasurer and assistant secretary; and William M. Bacon, Butte, Montana, was continued in office as general manager. It is said that two of the directors, including Mr. Ormsbee, will immediately resign from the directorate, as they were only representing New York stockholders unable to be present. The next meeting of the board will be held in New York on October 7.

MICHIGAN

HOUGHTON COUNTY

It is estimated that the following daily tonnage of ore is being produced from the copper mines, in spite of the strike:

Mine.	Present output.	Normal.
Calumet & Hecla	3600	9,000
Quincy	600	3,500
Victoria	600	500
Champion	500	3,000
Superior	350	600
Baltic	300	2,800
Trimountain	300	2,200
Osceola	300	3,000
Isle Royale	250	1,800

Total 6800 26,400

The Copper Range Consolidated mills, the Baltic, Cham-

pion, and Trimountain, are being overhauled, advantage being taken of enforced idleness to do this work. The re-grinding plants being installed will save from 1½ to 2 lb. of copper per ton of ore stamped. The annual supply of coal for these properties, 122,000 tons, has been nearly all delivered. The Calumet & Hecla Mining Co. has received the hull for its new dredge to be used in digging the conglomerate sand from Torch lake for the regrinding plant. It will weigh 450 tons when complete, and will handle 10,000 tons per day. The machine was made by the Bucyrus company.

James Pollack, a deputy sheriff, was killed on October 8 by copper mine strike sympathizers at the Isle Royale mine, near Houghton. The State Supreme Court issued an order requiring Judge O'Brien, of the Houghton County Circuit Court, to immediately renew and place in force his injunction of September 20 restraining picketing, which he recently dissolved.

MONTANA

BROADWATER COUNTY

(Special Correspondence.)—The Boston & Idaho Mining Co., operating dredges in Boise basin, Idaho, has a drilling crew at work on Crow creek, near Radersburg, testing the gravels with a view to erecting a dredge. The Ohio mine at Radersburg is shipping about 600 tons per month to the Anaconda smelter.

Radersburg, September 30.

LEWIS AND CLARK COUNTY

(Special Correspondence.)—The Stemwinder property, in the Grass Valley range, is under option, and is being prospected by a shaft. The Rock Rose shaft, in the same district, is being unwatered.

Helena, September 30.

MADISON COUNTY

(Special Correspondence.)—The success of the dredges of the Conrey Placer Co., in which Harvard College people are interested, has led to the investigation of similar ground farther down from Ruby gulch. Options are being secured and drilling will be undertaken. The Missouri Mining Co. has recently purchased the Elling mining property, on North Meadow creek, near McAllister, and is preparing to develop and operate the property.

McAllister, September 30.

NEVADA

ESMERALDA COUNTY

The estimated September production of the Goldfield Consolidated Mines Co. is as follows: Ore treated, 27,965 tons; gross value recovered, \$338,000; operating expenses, \$186,000; net realization, \$152,000.

Active mining operations, with ample financial backing, and with what are regarded locally by the best authorities as excellent prospects for success, are being conducted on a number of properties in the Goldfield district, including the Goldfield Consolidated, Merger Mines, Florence Goldfield, Jumbo Extension, Goldfield Oro, Blue Bull, Booth, Silver Pick Consolidated, Sandstorm-Kendall, C. O. D. Consolidated, Lone Star, Goldfield Vernal, Nevada Eagle, Nancy Donaldson, Diamondfield Black Butte, Goldfield Belmont, Diamondfield Daisy, Great Bend, Crackerjack, Yellow Tiger, and New Jersey Mines Co.'s properties, and within a short time work will be in progress at a number of other properties.

NYE COUNTY

The quarterly statement of the Belmont company shows that receipts from ore and bullion were \$940,521, and net earnings \$543,584. The available cash resources on August 31 were \$1,466,919. The shaft vein is opening in a splendid way, especially on the 1166-ft. level. A raise from the drift under the Murray vein on the 850-ft. level of the Extension has opened the shoot, which contains some good ore. The Jim Butler winze, below No. 6 level, is down 26 ft. in rich sulphide ore. On the 1000-ft. level of the Halifax there is profitable ore in three faces. The winze below the 600-ft. level of the West End is down 30 ft. On the 1170-ft. level of the Merger the orebody has proved

to be wider than expected. There has been a general change of officials at the North Star mine, J. W. Chandler being the new manager. Active development is under way at the 1200-ft. level of the Buckeye-Belmont. During the week ended October 4, the mines at Tonopah produced 11,927 tons of ore valued at \$281,170.

STOREY COUNTY

A new 1000-gal. per minute capacity Starrett pump is being fitted ready for work at the 2500-ft. level of the C. & C. pumping shaft, to lower the water to the 2700-ft. point. Bronze working parts are being substituted in the pump where necessary. There will be two of similar capacity for this work. It is stated that San Diego people have secured control of certain holdings on the Carson river which contain the tailing discharged from old mills crushing Comstock ores years ago. There is estimated to be great quantities of quicksilver and silver in the tailing, and operations are to be started at an early date.

WHITE PINE COUNTY

The Ely Consolidated has shipped its third car of copper and silver ore to Salt Lake, Utah, smelters. Development in the Copper Queen on Lode B has opened 18 in. of 20.83% copper and 32.4 oz. of silver ore. The Morgan group is opening well, and on one drift is 30 in. of 2.73% copper, 15% lead, and 30.28 oz. silver ore.

UTAH

SUMMIT COUNTY

Ore production of the Park City district in September totaled 7701 tons, divided among the different mines as follows: Silver King Coalition, 4004 tons; Daly-Judge, 1404; Daly West, 1338; Ontario Silver Mining Co., 407; creek Jigger, 104; Grasselli Zinc Co., 96; Beggs and Miller, 45; Frank Daley, 34; Thompson-Quincy, 76; American Exploration Co., 166; Summit Leasing Co., 96; and Mines Operating Co., 34 tons.

WASHINGTON

FERRY COUNTY

(Special Correspondence.)—W. R. Foley, of Denver, Colorado, has bonded and leased the Phil Sheridan group of three claims, and the Stemwinder claim, in Sheridan camp, about 14 miles northwest of Republic. A 5 to 6-ft. vein on the Phil Sheridan has been partly developed, and the ore-shoot opened assays about \$75 per ton, mainly in silver. Republic, October 3.

The Republic district is quite active at present. The Imperator-Quilp company, having a bond on the Quilp mine, has leased the workings, and the lessees are shipping their first car of ore. The Knob Hill company is shipping 55 tons per day to the San Poil Consolidated mill. The Ben Hur Leasing Co. is employing 46 men and will soon increase the number. During August the Company shipped about \$24,000 worth of ore to the smelters. In September the Company sunk the main shaft on the Ben Hur mine, from the 500-ft. toward the 600-ft. level; shipped a considerable quantity of ore and broke down about 1500 tons ready for shipment.

Boyle Bros. are operating a diamond-drilling plant on the Lame Foot group of claims and another on the Oversight group for the Granby Consolidated Mining, Power & Smelting Co. (British Columbia), having bonds on these and adjacent mines.

The Hall Creek Mining & Milling Co., owning mines in Meteor camp, in the southeastern part of the county, is installing a power-plant and concentrator to handle 75 tons of ore per day. The power will be developed from Hall creek, which will generate 270 horse-power. At the Surprise, the 700-ft. level is opening in a promising manner. This property has produced a total of \$1,434,000 from above the 700-ft. level.

Plans for the rehabilitation of the North Washington Power & Reduction Co., which has an ore-treatment plant at Republic, are beginning to take definite form. About \$10,000 was subscribed at a recent meeting to pay labor expenses, while \$15,000 will be necessary to overhaul the mill, as estimated by Harry W. Newton, the superintendent.

STEVENS COUNTY

(Special Correspondence.)—Development work has been resumed on the Butte and Washington mine, near Orient. C. H. Walters, the manager, reports that the last sample from the International vein assayed \$7.22 in gold and 2.5 oz. in silver per ton. The sample was taken for 35 ft. across the vein. A shaft has been sunk 25 ft. on a cross-vein on the Audrey mine, on Toulou mountain; the vein is 30 in. wide and is reported to be rich. In the Chewelah district, the Butte-Chewelah Copper Co. has opened rich ore and is installing an engine and compressor to help development. The Copper King mine has completed a raise which connects the lower with the upper levels and gives air circulation sufficient to ventilate all of the stoping ground on the 500-ft. level. The Company will now ship a car-load of ore per week.

Chewelah, October 2.

Electric power is now used at the United Copper mine, and the new concentrating plant will soon be in full operation.

CANADA

BRITISH COLUMBIA

In a report issued by the officers of the British Columbia Copper Co., Ltd., it is estimated that the production for August 1913 was 700,000 lb. of fine copper, 2400 oz. of gold, and about 12,500 oz. of silver. The report for eight months, including August, shows 5,590,624 lb. of fine copper, 16,103 oz. of gold, and 81,023 oz. of silver. During the first half of the year, \$120,000 was spent on examining new properties. Last month a blast was fired on the Mother Lode mine which is said to be one of the greatest in the history of mining. Twenty-five tons of 40% giant powder was used, and there were 4123 holes drilled, each 15 ft. deep. This blast brought down 45,000 tons of ore and was completely successful. This is estimated to be about a year's supply of ore.

ONTARIO

At Porcupine, the concrete work for the additions to the Dome mill is almost finished. The main shaft of the mine is down 425 ft. Early in the current month the

GEOLOGICAL SECTION OF COBALT DEPOSITS.

directors will visit the property. The 10-stamp mill at the Three Nations is crushing from 40 to 45 tons per day, but the tube-mill has not been installed yet. A new tube-mill has been installed at the Porcupine Crown mill, and the stamp-mill will then have a capacity of 100 tons per day. A winze, in the mine, is down 30 ft. below the 400-ft. level, and shows ore for the full width. The south drift on the 300-ft. level has opened the rich shoot in the two upper levels. One hundred and fifty shareholders of the Three Nations Mining Co. visited the property of the Company on October 6 and 7. A new shoot, worth \$12 per ton, has been opened on the 390-ft. level of the McIntyre. During September the mill treated nearly 200 tons of ore per day.

Ore shipments from nine Cobalt mines during the week ended September 26 totaled 434 tons, and the Nipissing sent 118,321 oz. of silver to London. On October 20 this company will pay a dividend of \$450,000, making a total of \$10,890,000 to date. At the Cobalt Lake No. 6 shaft, No. 2 cross-cut has opened a 2-in. vein of cobalt and silver assaying from 1000 to 1500 oz. per ton. It is evidently parallel to No. 2 vein. A cross-cut is being driven

toward the north end of the lake on the 225-ft. level from No. 4 shaft.

As the Kerr Lake, Crown Reserve, and Cobalt Comet (Drummond) mines are dependent for their water-supply on Kerr lake, which is now being drained, a pumping plant has been installed on Giroux lake to supply them with water for all purposes. This plant consists of two motor-driven turbine pumps, each with a capacity of 500 gal. per minute, taking water from a well sunk in rock at the lakeside, and connected to it by a blasted-out passage. The water is pumped through an 8-in. pipe against 125-ft. head to a 46,000-gal. receiving tank, whence it is piped to the different mines.

MEXICO

SONORA

During September 350 cars of ore, concentrate, and bullion, valued at \$3,305,100, were exported from this state through the 'port' of Agua Prieta. The Nacozari mine shipped 11,985 tons, and El Tigre 72 bars of bullion and 40 cans of precipitate.

The Moctezuma-Arizpe Development Co. is installing oil-engines and a new air-compressor at the mill, which is about 18 miles southeast of Cananea.

Mineral Production of California

The following is advance data from the 1912 annual statistical report of the State Mining Bureau:

Substance.	Amount.	Value.
Asbestos, tons	90	\$ 2,700
Asphalt, tons	250,000	2,500,000

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

C. S. HERZIG has gone to Butte.
HOWARD D. SMITH has gone to London.
F. W. BRADLEY has returned from Alaska.
H. V. WINCHELL has gone to Cripple Creek.
THOMAS CHARLTON has gone to Northern Nigeria.
C. H. MONRO has returned from British Columbia.
F. C. ALSDORF has opened an office at San Francisco.
F. G. COTTBRELL has returned from Butte and the East.
A. R. CANNING has returned to England from West Africa.
W. F. STEVENS, recently of Arequipa, Peru, is in London.
ALLEN BARCLAY has gone to Burma on a professional visit.
P. D. BURTT has returned from Shushana and southwestern Alaska.
W. A. PRICHARD has gone to Colombia, to examine a placer property.
J. G. McMILLAN has been appointed mining inspector for Northern Ontario.
SEELEY W. MUDD was in San Francisco over Sunday, returning from Denver.
CHARLES C. SELBIE has returned from Korea and is now at Pasadena, California.
C. M. EYE is superintendent for the Imperial Reduction Co. at Ogilby, California.
WARREN A. LESTER, of Las Vegas, Nevada, is in San Francisco on mining business.
J. A. HOLMES has left Valdez for Seattle. He will be in San Francisco about October 16.
RALPH S. G. STOKES is making examinations in the Stewart district of British Columbia.
W. B. TUCKER, recently with the Calera Mining Co. of Chihuahua, has returned to San Francisco.
E. Z. BURNS of the firm of Simonds and Burns, New York City, is in Colorado on professional business.
E. J. WAGOR has been appointed superintendent of the melting and refining departments of the San Francisco mint.
CHARLES A. BANKS, manager of the Jewel-Denoro Mines at Greenwood, B. C., is examining properties in the Province of Quebec.
C. K. LEITH and G. P. CROSBY were in New York last week to testify in the dissolution suit against the U. S. Steel Corporation.
FREDERICK G. CLAPP has returned to Pittsburgh and will devote the next few months to the preparation of reports on foreign oil and gas fields.
HALL MACLAY CROSMAN, until recently with the American Smelting & Refining Co. at Charcas, San Luis Potosi, Mexico, is at New Rochelle, New York.
R. T. MISHLER, of the Tigre Mining Co., and JAMES W. MALCOLMSON have completed an examination of the Little Charlie mine at Mogollon, New Mexico.
D. C. JACKLING, C. M. McNEIL, CHARLES HAYDEN, and K. H. BARBIT are making a tour of inspection of the properties of which Mr. Jackling is the general manager.
JOHN M. BOUTWELL, consulting geologist for Phelps, Dodge & Co., having finished his report of the property of the Detroit Copper M. Co., has left Santa Barbara for Globe, where he will make an examination of the property of the Old Dominion Copper M. & S. Company.
Among the geologists composing the excursion party to Alaska are H. ARLT, A. SCHENCK, L. DE BUGGENOM, F. VON GROTE, J. MOREL, H. HAUSEN, J. McLEISH, E. MAIER, E. DE MARGERIE, E. S. MOORE, W. K. TEISSEYRE, A. W. C. WILSON, F. BASCOM, H. RIES, JAMES M. WORDIE, B. R. MURRAY, AUGUSTINE BAKER, PAUL ZOUBE, E. STOLLEY, T. F. WOLFF, C. KIDO, F. R. VAN HORNE, E. ROMER, and H. LUCK.

EASTERN METAL MARKETS.

(By wire from New York.)

NEW YORK, October 9.—The copper market is easier, with no demand. The London market closed steady with spot at £73 2s.6d. and futures at £73. A slight decline is to be noted in the price of copper, the average wholesale quotations of the New York market declining to 16.27. Despite the recent report of the Copper Producers' Association, very little support is being given to the copper stocks. The weak feature of the report was in the domestic demand, which shows a decrease of 6,800,000 lb., and the total deliveries both domestic and foreign showed a decrease of almost 7,000,000 lb. Lead and spelter are weak. Their sale is being pressed.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

Date.	Average week ending

The falling off in American supplies, so far this year, is reflected in the total amount of the imports of silver bullion from the United States, Canada, and Mexico for the first eight months of the year. The figures are given below, together with those for the corresponding periods in 1912 and 1911.

	1911.	1912.	1913.
Ounces	86,098,660	78,187,081	74,071,113
It is worthy of note that the total imports from Australia and New Zealand for the same periods were:			
	1911.	1912.	1913.
Ounces	422,875	547,006	1,215,335

Recent figures from Japan, relating to the silver movement in that country, show to what extent the metal is being parted with. Exports of 7,133,304 yen are offset by imports of 1,163,755 yen, leaving net exports of 5,959,549 yen. The net exports of 1911 were 1,369,126 yen, and for 1910 were 2,430,268 yen. Japan's production of silver is usually somewhat less than 5,000,000 yen, according to Pixley & Abell's circular.

COPPER

Quotations on copper as published in this column represent average wholesale transactions on the New York market and refer to electrolytic copper. Lake copper commands normally from 1-5 to 1-4c. per lb. more. Prices are in cents per pound.

On the whole the market was dull last week. Week before last the market weakened and sales in small lots were made at about 16½c., while the producers' figure declined from 17 to 16¼c. per pound. On Monday, September 29, there were sales of small lots around 16½c., and the market was unchanged. On Tuesday, light sales at 16½c. were made for December delivery by the large sellers. This was

reflected the next day in higher prices asked by the small dealers. On Thursday a fair amount of copper was sold to European buyers, and the producers exhibited more optimism. No sales of importance were recorded on Friday, and the week closed with both sides awaiting the report of the Copper Producers' Association on Wednesday. Exports of copper for the week ended October 2 totaled 10,174 tons. Foreign fortnightly statistics were reported on October 2 and revealed a further shrinkage in the stocks and visible supply of the metal abroad. Stocks decreased 1513 tons, and the visible supply in England and France and afloat on October 1 was 22,553 tons, a falling off of 3488 tons in the fortnight. The visible supply at Rotterdam, Hamburg, and Bremen on October 1 was 5295 tons, a decrease of 631 tons. Rotterdam stocks decreased 400 tons, Hamburg fell off 261 tons, and at Bremen a small increase was noted. The total of exports of copper from the United States during September was 77,000,000 lb., as compared with 51,144,000 lb. last September.

QUICKSILVER

The primary market for quicksilver is San Francisco, California, being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

TIN

New York prices control in the American market for tin, since the metal is almost entirely imported. San Francisco quotations average about 5c. per lb. higher. Below are given average monthly New York quotations, in cents per pound:

COPPER PRODUCERS' ASSOCIATION REPORT

The Copper Producers' Association statement, October 8, shows a decreased surplus. The details are as follows:

Pounds.

Stock of marketable copper of all kinds on hand at all points in the United States, September 1, 1913	38,314,137
Production of marketable copper in the United States from all domestic and foreign sources during September	131,401,229
Deliveries for consumption, September	66,836,897
Deliveries for export, September	73,685,275
Stock of marketable copper of all kinds on hand and at all points in the U. S., October 1....	29,793,094

Recent changes in surplus have been as follows, in pounds:

	Increase.	Decrease.
September 1912	16,364,213	
October	13,679,380	
November	9,419,095

Company Reports

TROITZK GOLDFIELDS, LIMITED

The Company was registered in 1906 to acquire from the Siberian Proprietary Mines, Ltd., the Preobragensk and Alexendrosk, Andreyevsky, and Vwarensky gold mines in the northwest part of the Kotchkar goldfields, province of Orenburg, southeast European Russia, and 49 miles south-southeast of Bishkil station on the main Siberian railway. The property is held on perpetual lease from the Russian Government and was taken over as a going concern, having been worked by former owners for several years, and equipped with milling, cyaniding, and a chlorination plant. The capital is £625,000 in 124,993 priority, and 500,007 ordinary shares of £1 each; 105,488 priority and all the ordinary shares are issued and fully paid. The report for the year ended January 13, 1913, states that the trial run of the mill and cyanide plant extensions commenced in July, and by August the installation was running normally. The new slime plant also came into operation in July, and during the few months the plants were in operation 23,793 tons of ore was milled, with the following results:

Ore milled, tons.....	23,793
Gold by amalgamation, ounces.....	4,662
Cyanide plant operation:	
Sand leached, tons.....	11,755
Slime filtered, tons.....	9,205
Concentrate produced, tons.....	150
Gold from cyanidation, ounces.....	1,486
Total extraction, per cent.....	82.95
Value of yield.....	R.*246,135
Total expenditure	252,983

*1 ruble = 51.5 cents.

There is an increase of R. 1.032 per ton in operating costs as compared with the previous year, chiefly due to the abnormally high cost of cyaniding. The value of the ore milled is 1.8 dwt. per ton less than that milled during 1911, due to the larger amount of waste broken, and to a faulted zone met with at the 680-ft. level. The ore reserves were estimated at 26,270 tons of a value of 7 dwt. (R. 14) per ton, besides which there was 1,199 tons of broken ore at surface, produced by mining operations during the year. In addition there is 1,950 tons of ore as pillars and arches, not available until the 500-ft. level is abandoned. The output from all sources was valued at £26,000, against which the total expenditure in Russia amounted to £26,608, thereby showing a working loss of £599. The net result for the year is a loss of £14,028.

THE OFFIN RIVER GOLD ESTATES.

The company was registered in 1900 to adopt an agreement with the Offin Syndicate Ltd. and to acquire a property of about 40 sq. miles, including the right to dredge the river Offin and its tributaries, in the Gold Coast Colony. Additional property has since been acquired, making 100 sq. miles now held and 158 miles of river. Four dredges are at work. The Offin Rubber Plantations Ltd. has been formed to develop a portion of the property for the cultivation of rubber. During 1910 an exclusive property license was acquired over 2½ sq. miles of tin-mining property, about 20 miles southeast of Naraguta, in Northern Nigeria. A mining lease has been secured over 720 acres, of which 81 acres have been proved and are estimated to contain 1,717 tons black tin. An exclusive prospecting license over 3¼ sq. miles situated to the northwest of the before mentioned property has been acquired and an application has been made for two square miles adjoining. Tin concentrate is recovered by means of calabashing. The capital is £300,000, in 45,000 7% preference and 252,920 ordinary shares of £1 each; 30,000 preference and 252,920 ordinary shares are issued and fully paid. The active profit for 1912 was £3,888. One dredge was laid up for the year, and the operations of the other three machines seriously hampered by light rains and the consequent low state of the river, yet the value of the gold output was only £1,156 15s 3d less than in 1911. The expenditure on the Nigerian tin properties amounted to

£4,709, but tin concentrate was recovered to the amount of £1,854. The proceeds of the bullion recovered by the dredges was £22,184.

ABBONTIAKOON MINES, LIMITED.

The company was registered in 1909 and is an amalgamation of the Abbontiakoon Mines Ltd. and Abbontiakoon Block 1 Ltd. The property consists of leases for 99 years from December 1880, of the mining, surface, timber, and rubber rights over the Abbontiakoon concession, near the town of Saskeva, Nassaw district, Gold Coast Colony. It is connected with Secondee, a distance of 40 miles, by the Gold Coast government railway. Ball-mills and cyanide plant were erected but were subsequently dismantled and a new mill of 25 stamps (1,680 lb. each), two tube-mills and sand and slime plant have been erected, with a capacity of 11,000 tons monthly. The capital is £625,457 in 1,250,915 shares, 221,285 shares are under option at par, leaving 127,800 shares in reserve. There is a loan of £140,000 from the Fanti Consolidated Mines Limited, and the Gold Coast Amalgamated Mines Ltd., \$55,000 have been repaid since the beginning of this year, leaving £85,000 outstanding. The mine has been running in a normal condition since October. Surface construction work was completed in June, and the mill started regular crushing in July. Since that date 46,415 tons of ore has been crushed and £78,841 worth of gold produced, giving a profit of £8,432 or 3s 7.59d per ton. The average working costs from July until December were 30s 4.07d per ton. It was necessary to recruit raw natives from Nigeria and the northern territories, but given a sufficient supply of native labor so that 11,000 tons of ore could be crushed monthly, there should be no difficulty in reducing working costs to 25s per ton. The total ore developed during the year was 24,958 tons. The cost of 21,555 tons exposed during the December quarter was 1s 2.52d per ton. At December 31 629,942 tons, of 10 dwt. gold content, and 309,012 tons, of 3.5 dwt., was developed or exposed, calculated over a minimum stoping width of 48 inches. The total receipts for the year were £79,440, leaving a debit balance for the year of £2,462.

CENTRAL ZINC COMPANY, LIMITED.

The company was registered in 1906 to acquire zinc distilling works in England, and has entered into a contract with the Sulphide Corporation, Ltd., whereby the latter undertake to supply from the Central mine, Broken Hill, N. S. W., for 10 years from January, 1907, zincblende up to 50,000 tons per annum. Smelting works have been erected at Seaton Carew, near the mouth of the Tees river, Durham, capable of treating 40,000 tons per year. The capital is £150,000 in 150,000 shares of £1 each; all the shares are issued and fully paid. The report for the year ending March 31, 1913, states that operations were not resumed for a month at the beginning of that period, on account of the then-existing coal strike. The influence of the strike, in the increased price of coal, was felt for a long period. The year closed with the best results yet achieved in the history of the company, however. The roasting plant proved ample for all purposes and 7,608.54 dry tons of ore was roasted. The number of retorts made totalled 11,952, together with 25,076 condensers. The distilling furnaces handled 8,972.55 tons of ore, producing 3,066.14 tons of spelter, 23.42 tons blue powder, and 41.51 tons metallic lead. The argentiferous lead residue totalled 6,270.82 tons. The concentrating plant treated 6,270.82 tons of residue yielding 3,229.64 tons of concentrate. The total expenditure for the year was £35,071. The profit for the year was £9,146, of which £2,788 is due to the Sulphide Corporation, Ltd., as their share under arrangement for joint account working, leaving a balance of £6,368, which is applied in reductions in the amount of expenditure to be written off, as per balance-sheet of March 31, 1912.

THE production of lead ores in 1912 increased about 500,000 tons compared with 1911. The yield of lead concentrates from the Central States (mainly from Missouri) was 256,838 short tons. Idaho, the largest producer in the Western States, contributed 176,704 tons.

Book Reviews

THE DAWSON NEWS. Discovery Day Edition, August 17, 1913. P. 74. Ill. The Dawson News Publishing Co., Dawson, Yukon Territory.

This is an interesting publication covering the discovery of gold in 1896 by Robert Henderson, the gold output to date approximating \$175,000,000, work of the Yukon Gold Co., dredging and hydraulic work, gold quartz and copper mines in the territory, climate, transportation, wild animals, and other details concerning a generally little known country.

FUR-FARMING IN CANADA. By J. Walter Jones. Commission on Conservation, Canada, publication. P. 166. Ill., maps, index. The Mortimer Co., Ltd., Ottawa, 1913.

The ruthless slaughter of fur-bearing animals in the world in past years and at present, which amounts to from 400 sea-otters to 71,500,000 rabbits per annum, with no provision made for keeping up the supply of the more valuable animals, has reduced the supply to a low point. The raising of these animals and their regular killing for furs is a comparatively new industry in Canada, and is a move in the right direction. The book under review is full of interest as to the habits and value of certain animals now being raised on these farms.

ENGINEERING AS A PROFESSION. By A. P. M. Fleming and R. W. Bailey. P. 286. John Long, Ltd., London. For sale by the *Mining and Scientific Press*. Price, \$1.

In this book the attempt is made to give a concise view of the scope of training necessary for an engineer and of the opportunities for advancement. Mr. Bailey's experience as principal of the Technical Institute at Crewe gives weight to what is said as to the training of engineers. The bulk of the book, filled with matter relating to the cost of training methods, of obtaining appointments, and schedules of civil service examination, is based almost entirely upon conditions in Great Britain and is therefore of little direct use elsewhere.

INTRODUCTION TO THE STUDY OF IGNEOUS ROCKS. By G. J. Finlay. P. 228, index, Ill., tables. McGraw-Hill Book Co., New York, 1913. For sale by the *Mining and Scientific Press*. Price, \$2.

This is an excellent little book of pocket size, with flexible backs, and contains in convenient form the essential facts necessary to determination of igneous rocks likely to be met by mining engineers. The different chapters cover 'Qualitative Classification of Igneous Rocks,' 'Determination of Igneous Rocks in Hand Specimens,' 'Movement of Light in Crystals,' 'Identification of the Essential Minerals of Igneous Rocks,' 'Description of the Accessory Minerals of Igneous Rocks,' 'Igneous Type Rocks,' 'Varietal Rocks Related to Type Rocks,' 'Method of Describing Rocks,' 'Outline of the Quantitative Classification.' Mr. Finlay is a competent petrographer, has made an excellent selection from the material available, and has written a highly useful book.

THE GEOLOGY OF KALGOORLIE. By C. O. G. Larcombe. P. 315. Ill., maps, plans, index. Australasian Institute of Mining Engineers. Melbourne, Victoria, 1913. For sale by the *Mining and Scientific Press*. Price, \$4.

This valuable work has been printed and in circulation among members of the Australasian Institute of Mining Engineers since 1911 and is now for sale to the public. The volume is the outcome of three years' study, and has been written, not only as a scientific exposition of the geology and occurrence of the ore deposits of Kalgoorlie, but, at the request of various mining people, with the object of initiating those interested into some of the more important places connected with the mining geology of the district. In this respect the work must of necessity differ from a purely technical monograph. When first published we commented on Mr. Larcombe's work, and we have made short extracts since from time to time, so there is no

need here to cover the same ground again. The book is well arranged, excellently illustrated, and the printing and binding is also good. It bids fair to become a standard text-book of reference on the geology of this important district.

CYANIDE PRACTICE, 1910 to 1913. Edited by M. W. von Bernewitz. P. 732. Ill., index. San Francisco, 1913. Published and for sale by the *Mining and Scientific Press*. Price, \$3.

This book forms the third in the series of reprints from the MINING AND SCIENTIFIC PRESS of articles on cyanidation that was begun by T. A. Rickard in 1907, and it is of the same general character as the preceding volumes, 'Recent Cyanide Practice,' and 'More Recent Cyanide Practice.' The name is indicative of the scope of the work, and the volume consists of a wide variety of individual papers on cyanidation, all having in common the trait of centring interest on practice. Collectively they afford an unexampled picture of the state of the art at the beginning of the year, and individually they throw light upon nearly every phase of the work of the present-day cyanidationist. The book brings together and preserves in permanent form the experience and observations of nearly 200 men engaged in the actual operation of cyanide mills in the United States, Canada, Mexico, Central America, Korea, Australia, South Africa, and, indeed, wherever potassium cyanide is used to dissolve gold. The list of authors includes E. M. Hamilton, A. W. Allen, S. J. Truscott, H. Stadler, F. C. Brown, Noel Cunningham, W. P. Lass, J. W. Hutchinson, A. J. Yeager, A. Grothe, E. L. Oliver, W. J. Sharwood, W. A. Caldecott, Philip Argall, F. C. Landguth, A. E. Drucker, Alfred James, and many others too numerous to mention, who are widely known for their excellent work. A not unimportant portion of the book was written by its editor, who from extended operating experience in New Zealand and Australia, supplemented by wide reading and study in the United States, has brought to the task of compiling this volume especial competence as well as enthusiasm. Mr. von Bernewitz has arranged the abundant material under the following heads: Historical; Chemistry of Cyanidation; Special Problems; Crushing; Concentration and Treatment of Concentrates; Roasting; Agitation; Decantation; Filtration; Precipitation and Clean-up; Disposal of Residue; Measurement and Estimation of Tonnages; Recent Cyanide Practice by Districts; Description of Notable Mills; Review of Progress by Years.

The book is a sifted compendium of facts that will promptly take rank as one of the indispensable handbooks of the cyaniders.

PREVENTION OF ACCIDENTS. General rules issued by the Safety Department of the Copper Queen Consolidated Mining Co., Bisbee, Arizona. P. 23. This department of the well known copper mining company was formed to try and reduce the number of serious and minor accidents occurring at the mines and smelters, which, besides injuring employees and incapacitating them from work, is a source of worry and expense to everybody concerned. The prevention of accidents by all possible means is a personal duty which everyone owes not only to himself, but also to his fellow workmen. This little pamphlet deals with 87 different subjects, and should be secured by miners and millmen alike.

MINING MAP OF SONORA, MEXICO. Compiled by S. M. Greenidge, Douglas, Arizona. Size, 36¾ by 49¼ inches. Scale, one inch to 11.8 miles. For sale by the *Mining and Scientific Press*. Price, in folder for pocket use or on rollers, \$2.

Sonora is one of the most important mining states in Mexico, and the map under review has been executed with care, to show every mining centre of the state. While this state is somewhat disturbed at present, there is sure to be a large return of mining men when affairs are settled, necessitating the use of a reliable map.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

APPLICATION for patent should, when possible, be made in the spring rather than fall, since, in case examination of the claim becomes necessary, delay may ensue by reason of the impossibility of making examinations at high altitudes in the winter.

THE QUESTION as to real or personal property in respect to mining equipment is often the subject of great difference of opinion when it comes to deciding the question of ownership. A track laid in an adit in a more or less permanent manner is a fixture and passes with the real property, regardless of change of ownership, unless some special provision in the lease gave the lessee the right to remove the equipment. A mine-car is personal property and may be recovered by its owner at any time prior to the lapse of the three-year period of limitation.

ROTARY ROASTING FURNACES give satisfaction in treating zinc and other ores and in calcining cement-making materials. In Mexico there are two 4 ft. 8 in. by 40-ft. furnaces roasting zinc ores, and the Power & Mining Machinery Co. has made one 10 by 150 ft. The lining is usually of fire brick, 4 in. thick for small machines, and up to 12 in. for the firing zone of the larger ones. They are mounted on rollers, and inclined from $\frac{3}{4}$ to $\frac{1}{4}$ in. per foot. Speed varies from 1 to $\frac{1}{2}$ r.p.m., fuel consumption ranges from 250 to 750 lb. per ton of ore being roasted, and, according to size, the machines could handle from 36 to 600 tons per day.

DISCOVERY is a prerequisite to the patenting of mineral land in the United States, and the Supreme Court has said: "While the statute does not prescribe what is necessary to constitute a discovery under the mining laws of the United States, it is essential that it give reasonable evidence of the fact either that there is a vein or lode carrying precious minerals, or if it be claimed as placer ground, that it is valuable for such mining, and where there is not enough in what the locator claims to have seen to justify a prudent person in the expenditure of money and labor in exploitation, this court will not overthrow a finding of the lower court that there was no discovery. It is the policy of the Government to favor the development of mines of gold and silver and other minerals, and every facility is afforded for that purpose, but it exacts a faithful compliance with the conditions required. There must be a discovery of mineral and a sufficient exploration of the ground to show this fact beyond question. If the lands contain gold or other valuable deposits in loose earth, sand or gravel, which can be secured with profit, that fact will satisfy the demand of the Government as to the character of the land as placer ground."

ELECTRICITY was used in the Butte district, Montana, prior to 1902, only for lighting, tramping of ore on the surface, and electrolytic refining of copper, according to John Gillie. It is now used for every purpose. The Anaconda Copper Mining Co. operates 10 main hoisting engines and 10 auxiliary hoists by compressed air, which is generated by six 7500 cu. ft. of free air each per minute air-compressors, driven by 1200-hp. synchronous motors. The air in rock-drilling operations is used at 85 lb. pressure, and for the large operations is usually furnished from three or four central plants, the smaller mines using individual machines. A total of 13,455 e.hp. is used for this purpose, and the voltage used is from 440 to 2200 volts. In draining the mines, electrically driven pumps are generally used, and a total of 4780 e.hp. is required. The large pumps are quintuplex vertical-plunger type, with a capacity of 600 gal. against a head of 1200 ft. The smaller units are of various types. Centrifugal pumps are not used on account of the acid nature of the mine waters. The mines of the Butte district are warm, due

to the oxidizing of the sulphide minerals, and forced ventilation is largely resorted to. Twenty-five hundred electric horse-power is used for driving ventilating fans. In addition to fans and blowers, compressed air is used after blasting to clear the mines of powder gases and foul air. Underground, the stations, main cross-cuts, and drifts are electrically lighted, as well as the surface plants and property. A total of about 1300 hp. is used for this purpose. Electric locomotives are being introduced in all tramping, both underground and surface, and this work requires 1860 e.hp. At Butte, Anaconda, and Great Falls, all the Butte ores are treated. In these ore-reducing plants, 24,177 hp. is used in driving concentrators and blowing engines, and in operating cranes, shops, and the different power machinery in connection therewith.

IN MANY REGIONS the settling of ground above extensive mine workings is of common occurrence and leads to serious damage to property on the surface, not only immediately above the mines, but often at considerable distances away, according to Ernest Howe. The force of gravity, exerted vertically downward, that tends to overcome equilibrium in a partly supported mass of rock or earth may be resolved into two components, one of which is in the direction of least resistance to movement; the angle that this component makes with the vertical has been called the 'angle of pull.' The surface area subject to disturbance depends upon the various angles of pull of the unstable ground, and a determination of these angles may sometimes be a matter of considerable importance. In a study made some years ago in the mountains of southwest Colorado, the causes that were believed to have been responsible for the numerous landslides were summarized as follows: Internal causes: (1) physical condition of the rocks: cohesion, jointing, presence of soft or incompetent layers; (2) structural conditions: folding, faulting; and (3) topographic conditions: oversteep hill-sides or cliffs. External causes: (1) earthquakes; (2) readjustment of stresses within the mountains; (3) saturation of the ground by water; and (4) frost. Probably the commonest of the external causes of landslides is saturation of the ground by water.

THE ore reserves of the Central Mining & Investment Co.'s properties, as calculated at the close of the financial year, are summarized as follows:

	Tons.	Value per ton.
1. Ore blocked out and available for stoping	32,512,087	31.3s.
(This represents an average of 3.20 years' supply for the mills.)		
2. Ore in sight which will be rendered available for stoping by current development operations	3,290,168	25.2s.
(This represents an average of 0.32 year's supply for the mills.)		
Total	35,802,255	30.8s.
This represents an average of 3.52 years' supply for the mills on measured ore reserves alone.		
3. Ore contained in shaft, safety, and boundary pillars is given in a subjoined detailed statement for each company.		

In addition to these reserves, a further supply amounting on the average to about 15% of the total output, is obtained from development rock and reclamation work. Close attention has been given on the mines of the group during the year to mining as little waste rock as possible, to confining the stope widths as nearly as is practicable to the actual widths of the profitable orebodies. This enables the proper inclusion in profitable reserves of bodies of ore which with less careful mining would remain below the profit limit.

The average rate of sorting for 1912 was 14.08% of the total tons mined. The ore reserves in classes 1 and 2 therefore represent 30,761,298 milling tons of a calculated gold content of 35.2s. per ton.

Production Statistics

SMELTER AND REFINERY PRODUCTS IN 1912.

The value of the metals produced from domestic ores, foreign ores, matte, and unrefined bullion smelted or refined in the United States in 1912, according to a report by J. P. Dunlop of the U. S. Geol. Survey, was \$995,798,618, compared with \$787,727,776 in 1911. The figures are approximate, as the value given for aluminum is that for consumption and includes the imported metal in addition to the production from domestic ores.

The quantity and value of the metals are given for both domestic and foreign sources, but it is necessary to add the value of the secondary metals recovered in 1912 in order to show the vast extent of the refinery and smelting industry in the United States. As the value of these secondary metals, which is exclusive of gold, silver, platinum, iron, and aluminum, amounted to over \$77,000,000 in 1912, it is reasonable to assume that the total value of the metals derived from foreign and domestic sources by the smelters and refineries in the United States amounted to over \$1,100,000,000. A portion of the increased value in 1912 was due to the much higher average prices for silver, copper, and zinc, but the production of all metals other than gold and antimonial lead increased in 1912.

The extremes in output are shown by the fact that 1.3 tons of platinum, 188.1 tons of gold, and 4,471.4 tons of silver were recovered from domestic and foreign ores and from foreign matte and unrefined bullion, while the production of pig iron, the largest output of pig recorded in the United States, amounted to 33,802,685 short tons. The yields of refined copper, 734,052 tons, and of spelter, 338,806 tons, were also the largest ever made. The consumption of aluminum in 1912 was 32,803 short tons, an increase of nearly 10,000 tons over that of 1911. Pig iron production increased over 7,750,000 short tons in quantity and over \$93,000,000 in value. Of the pig iron about 4 per cent was smelted from foreign ores. The quantity of spiegeleisen, ferro-manganese and other ferro-alloys marketed in 1912 amounted to 368,126 short tons, of which 39% was derived from foreign ores.

The gold from domestic ores amounted to \$93,451,500 and that from foreign ores, matte, and bullion to \$19,964,010. The value of the silver in 1912 from domestic sources was \$39,197,500 and that from foreign sources \$40,989,817, a total of \$80,187,317, or nearly \$11,000,000 more than in 1911. The output of nickel and of platinum, valued at \$17,936,800 and \$1,732,221, respectively, was derived almost wholly from foreign ores, matte, and bullion. The small yield of tin was derived from foreign ore, as the domestic ore, which came entirely from Alaska, was shipped to Great Britain for smelting. The value of the copper from all sources amounted to \$242,237,160, an increase of over \$63,000,000. The production of copper from domestic ores increased over 65,000 tons, while that from foreign ores and matte declined 48,000 tons. The lead from all sources was 6,000 tons less in quantity and \$540,000 less in value in 1912 than in 1911, the decline being due almost entirely to a lower smelter recovery from foreign ores, matte, and bullion. There was an increase of over 62,000 tons of spelter made from domestic ores, while that from foreign ores was about the same in 1912 as in 1911. The total value of the spelter increased from \$32,663,964 in 1911 to \$46,755,228 in 1912.

The largest increase was that of iron ores, which amounted to 46,023,540 short tons in 1911 and 63,859,728 short tons in 1912, an increase of over 38%. Most of the ore shipped was hematite ore from the Lake Superior region. Brown ore furnished only about 3% and magnetite less than 4% of the ore shipments. Manganese ores of high grade came mainly from Virginia and the rich manganiferous iron ores mainly from Arkansas and Virginia, while all the chromlum ore shipped in 1912 was mined in California. The figures for aluminum ore given in the table represent the domestic output of bauxite, mainly from Arkansas, Alabama, and Georgia. The figures given for gold ore include silicious, pyritic, and other alloys in which the predominant value is gold.

The following table shows the production of crude metallic ores supplied from domestic mines to gold and silver mills, concentrating plants, and smelters in 1911 and 1912, in short tons:

Ores.	1911.	1912.
Iron	46,023,540	63,859,728
Manganese	2,752	1,864
Manganiferous iron	3,006	3,247
Chromium	134	225
Tungsten	16,500	34,000
Titanium	6,900
Aluminum	174,292	179,040
Gold	9,884,684	9,736,203
Silver	739,200	848,574
Quicksilver	138,525	155,694
Tin	42,200	3,000
Vanadium and uranium	8,468	18,000
Copper:		
Western States	18,207,566	23,431,301
Central States	10,978,827	11,411,941
Eastern States	801,842	830,089
Total	29,988,235	35,673,331
Copper-lead	6,923	14,614
Lead:		
Western States	2,157,817	2,388,598
Central States	3,794,712	4,064,366
Total	5,952,529	6,452,964
Zinc and zinc-lead:		
Western States	1,356,781	1,344,222
Central States	10,629,269	11,899,185
Eastern States	413,332	497,832
Total	12,399,382	13,741,239
Grand total, tons.....	105,380,370	130,728,622

The table conveys in a striking manner the prominence of the mining industry in the United States. The total quantity of crude metallic ore from domestic mines in 1912 increased over 25,000,000 short tons compared with that of 1911. The output of nearly every kind of ore increased and all parts of the country shared in the prosperous conditions.

The production of silver ore given is mainly that of silver-gold ores in which the value of the silver exceeds that of the gold. Pure silver ore is rare in the United States. Of the 1912 production, Nevada (mainly Tonopah) is credited with 476,725 short tons, Colorado with 158,429 tons, New Mexico with 110,127 tons, Utah with 81,234 tons, and Texas with 20,375 tons. The Colorado output is largely iron-manganese-silver ore used as flux in lead furnaces.

No quicksilver ores were imported and of the domestic ore treated 130,926 tons was the output of California mines.

The production of copper ores increased 5,700,000 tons in 1912. The increases from the Lake Superior mines and from Tennessee, while substantial, were relatively small compared with the largely increased tonnage of copper ores treated in the Western States, amounting to over 5,200,000 tons. New Mexico, Arizona, and Nevada contributed the bulk of this increase, which consisted mainly of concentrating ores. The quantity of copper concentrate produced in 1911 was 2,202,590 tons; in 1912 it was 2,734,065 tons. The average content of copper in crude ore concentrated in 1912 was 1.26 per cent.

The production of zinc concentrate in the Central States amounted to 424,337 short tons in 1912, which came mainly from ores mined in Missouri, Wisconsin, Kansas, and Oklahoma. New Jersey was the largest producer of zinc ores in the Eastern States, and Colorado, Nevada, Utah, Montana, and New Mexico in the Western States.

The Survey report entitled 'The Production of Metals and Metallic Ores' is now in press. When issued, copies may be obtained upon application to the Director of the United States Geological Survey, Washington, D. C.

The report shows a general increase in production and expansion of the industry with special regard to the copper, lead, and zinc.

EDITORIAL

COAL MINING in Western Canada is showing a healthy growth, the shipments from the mines during a recent week being given as 69,000 tons, as compared with 59,000 for the same period last year.

THE decision of the Supreme Court of the State of Michigan, reinstating the injunction against the Western Federation of Miners and others, which prohibits picketing with its attendant disorder, comes as a timely relief to that district.

IF President Huerta's recent *coup d'etat* is to stand as a precedent for future Mexican executives, the relations between the executive and legislative branches of that government will never be other than harmonious. However, the element of personal risk that will be connected with the office of deputy, and the duties of this body, which will consist solely of putting the legislative O. K. on the dieta of the President, will not tend to make this a much sought after office.

RESULTS attained under the operation of the British Workmen's Compensation and Employers' Liability Acts during 1912 are of much interest to operators in this country. The general terms of these laws are too well known to need repetition. During the past year 424,406 cases of injury and 3599 death cases were compensated; the statistics covering 7,500,000 employes engaged in 136,279 industries. Two-thirds of the employes are factory workers, and the average annual charge for compensation there amounted to only \$1.25 per person employed. In mines the charge was \$5.35, the average for all industries being \$2.10. A most gratifying feature of the law is the small number of claims taken into the courts, only 5858 having been settled judicially, and of these, 76 per cent were awarded in favor of the workman.

THE colliery disaster at Cardiff, Wales, marks another of those seemingly unavoidable tragedies of mining which have marred the history of the industry since its beginning and which with each recurrence causes us to pause and consider whether the humane side of the industry is keeping pace with the technical. It is to be regretted that accidents and the loss of life have been and always will be associated with mining; but it only remains within the power of the operator to reduce such hazards to the minimum by fostering the 'safety first' movement and making use of every available means for the protection of life in the conduct of mining operations. To our Welsh friends, we ex-

tend our deepest sympathy and will hope that this calamity may be a stimulus to the work which is being done for the humanitarian side of mining.

THE adventures of a mine promoter, whose unavailing efforts to discover valuable mineral deposits were finally crowned with success through selling the mine water as mineral water, not long ago formed the subject of an amusing short story. The fiction is recalled by the suit of the Archipelago Islands, Ltd., to recover the value of 1000 shares of the United States Cobalt Company, which it had traded with a wine broker for an equivalent value in champagne. The perfidious broker sold the shares but failed to deliver the champagne, hence the suit. The incident not inaptly characterizes the effervescent quality of some kinds of mining finance.

Mining Law Revision Again

In reprinting this week the article opposing revision of the mining law from the *Bisbee Daily Review*, we give our readers the strongest and best statement we have seen on behalf of those who would let well enough alone in this case. We are confident that our contemporary under-estimates the amount of demand for change that comes from the mining people. Aside from other opportunities for judging, we have served on several occasions upon the resolutions committee of the American Mining Congress, and we speak from positive knowledge when we say that there is more than a vague unrest among mining men. There is indeed a fixed idea that the safeguards enumerated by the writer in the *Review* have not served to meet the needs of the situation and that some change is imperative. It is impracticable at this time to take up and discuss seriatim the points raised in the article, but as to one or two we wish to speak in some detail.

In practice it is not true that the mining law secures exclusive occupancy to a placer claimant prior to discovery, and this fact is the basis of great dissatisfaction in the oilfields. Under the United States mining law a mere locator of placer ground is unknown to its officers and prior to discovery has no rights. There is in fact no legal reason why the withdrawal act should not have been retroactive as regards locators. The state courts protect such a one merely as an incident to preservation of the peace. He is not permitted to fence the land claimed, because it is public land, and unless it be fenced it is difficult to prove trespass and so get the protection of the state courts. If without act of violence another can gain access to the land and first complete discovery, the title belongs to this second man and the first claimant loses everything, regardless of the fact that he may have been the first, by geological surveys or other means, to have determined the probable presence of oil, and regardless of his good faith and possibly heavy expenditure. The result of all this is the system of plowed furrows and shot-gun guards that anyone traveling through a new oilfield on public land must have seen. No one familiar with the fact may deny that among oilmen there is extreme dissatisfaction with the law. This is just one instance; others may be easily cited.

Another cause of great dissatisfaction is that while the people of the community may, it is true, reduce the size of claims in a district, they are not permitted to enlarge them, and under existing conditions the maximum claim is too small for many purposes. Out of this has grown a system of dummy and power of attorney locations and a whole tissue of fraud. The miner is naturally honest and straightforward. He wants to get away from this system. It is probably true that as a whole the miners are not asking for a leasing system, but it is also true, if we correctly judge current opinion, that the miners will consent to a modified leasing system, if thereby the area needed for economic operation may be honestly claimed and taken, and other defects in the law may be cured. At the same time he is but a poor judge of Eastern opinion, and in the end the majority must at least consent to any new law, who sees probability of getting changes in the mining law, without introduction of leasing, at least to some extent and to apply to some of the minerals mined.

Government Control of Strikes

New Zealand, through her Arbitration Court, has always held a unique position in the settlement of labor disputes, and up to last year adequate means were available through this court for the adjustment of these difficulties. However, after a great amount of hair-splitting it was decided that a strike is not a strike when it is a conference, and the five and six months conferences of last year resulted in a complete suspension of operations at Waihi and Reefton during these periods. The Government is about to undertake the solution of the conference difficulties whereby such conferences or strikes with their attending hardships to both labor and operator may be avoided. Surely this is a most laudable purpose for the government to undertake, and if the enactment of a law, equitable to both operator and miner, can rectify existing conditions, it might well serve as a pattern to be emulated by other nations. The bill, which is about to be presented to the New Zealand parliament provides *inter alia*, for a board representing both employer and employees, which will investigate all labor grievances and make such recommendations as seem advisable for settlement. If an agreement cannot be reached a vote will be taken and a bare majority will suffice to decide the issue submitted. Another provision in the bill is that if a union has voluntarily or penally had its privileges cancelled and a new union has been formed, the new union may not include in its membership any who have taken part in an unlawful strike. By this law all differences will be adjudicated by this commission and every worker and employee who, being bound by an award of the court, shall take part in a strike will be liable to a penalty up to £10 and a union which promotes it to a penalty up to £1000, and anyone who aids in a strike, even by contributing to strike funds, will be penalized. The stand being taken by the government against lawlessness and mob violence would indicate that this element in the conduct of strikes must be obliterated and a speedy, peaceful, and sane means substituted.

Revision of the Mining Law—A Protest

*With a profound appreciation of the study given by the committee on mining law of the Mining and Metallurgical Society of America to the question of revision of the present mining statutes of the United States, the writer is by no means prepared to admit that a revision of these statutes is necessary or even expedient. Further, the writer is very much disinclined to attach any weight whatever in this matter to opinions of mining congresses, recommendations of Directors of Geological Survey, of Secretaries of the Interior, and such. Mining congresses' opinions are influenced altogether by interested suggestions from without the mining industry. A properly conducted U. S. Geological Survey has nothing to do with the practical side of mining, its proper function being the conduct of accurate surveys of the surface structure of the country, that is to say of the topography and geology, and the publication of general maps of the surveys including the mining districts. The principal qualification of Secretaries of the Interior is that they shall have absolutely no practical acquaintance with mining. Why then should the opinions of these organizations and persons be considered seriously on this subject? The fact is that their opinions in the matter should not be considered at all.

Relation of New Laws to the Present Laws

It is a mistake to assume that "in many parts of the country the general inadequacy and many absurdities of our present system have become so irksome as to create a widespread demand for an entire new law." There is, indeed, a general feeling that something is wrong, and consequent on this that something should be done about it. But when investigations are carried beyond these two general conclusions, very little is found that is concrete and definite in statement as to what is wrong, and many loose-jointed ideas of the cure for the assumed wrong are put forward. The demand for an entirely new law is quite understandable under the circumstances. It is the easy political first-aid device of the politically shiftless proposed for any industrial ill. An entirely new law is popularly assumed entirely to obliterate the old law by putting it out of sight, and thus to save the effort required to understand the cause of the trouble from it. As a fact, the new law does nothing of the kind. The old law is not obliterated. The entirely new law ultimately appears in its true relation as an addition to the old, thus making more laws where less have been hoped for. Suppose, then, before academically discussing the comparative merits of so-called new entire mining laws proposed, that the existing United States mining statutes be reconsidered in search of what is wrong about them or through them.

The present mining statutes of the United States make an unconditional grant to citizens, or to persons who have declared their intention of becoming citizens, of the valuable minerals which may be found by them in unappropriated public land. The grant

is free. You find valuable minerals in the public land. You take possession of them as personal property. They forthwith become yours absolutely. There is no tax to pay. There is no paper to be signed. No claim of right to the possession of the land has to be made by locating it. This unconditional grant of valuable minerals free to the taker from unappropriated public land—that is from public land to which there is no claim—has been part of the statute law for 47 years. Do miners want this unconditional grant of free minerals withdrawn from them now? Are miners asking that they be compelled by law to pay for the valuable minerals which the law gives them free now? Well hardly. Then who are they that ask that all valuable minerals be sold by the United States to miners hereafter through leases under a leasing law? Why, the people who will be the collectors and spenders of the lease rent money—call it graft money for the sake of clarity.

Exclusive Occupancy of Public Land

The present United States statutes grant a conditional right of exclusive occupancy of public land for purposes of exploration for minerals. The right itself is free like the minerals when found. There is no fee or charge of any kind imposed by the United States statutes. There is no regulation for the occupancy of the land or of exploration in it which is provided for by the statutes. The conditional feature of the grant of exclusive occupancy of public land for mining purpose is that the law of such exclusive occupancy shall be the rules, customs, and regulations of miners which they themselves create for definite territories in the public land described as mining districts, with these limitations of authority that the miners could not make lawful any rules, customs, and regulations, under which (1) exclusive occupancy could be had of any land for exploration for minerals in rock in place without a precedent discovery of the lode or vein of the rock in place which might contain the valuable mineral, or could be had of a greater extent of land in a single claim than 1500 ft. along the supposed strike of the ledge or vein together with no more than 300 ft., and no less than 25 ft., width on each side of the lode line, making parallel end lines; (2) under which exclusive occupancy for exploration for minerals outside of veins or lodes of rock in place, as the statute expresses it, "of claims usually termed placers," could be had for more than 20 acres in a single claim by a single person, or for more than 160 acres in a single claim by eight persons, conforming in boundary to subdivisions of the public land survey where practicable; and (3) under which exclusive occupancy could be maintained by less than \$100 expenditure in labor and improvements annually on each claim or for its benefit. The United States statutes also enlarge the grant of free occupancy of the public land by grants of free timber from unappropriated public land for use in exploration and recovery of minerals, and free rights of way over the public land for mining ditches and waterways.

*From the *Bisbee Daily Review*.

Efficiency of the Present Laws

The writer confesses inability to understand how these provisions of the present mining statutes by themselves are inadequate or absurd. They confer the real law-making power over mining of the public land on the people interested locally in the mining. Within the limits set by the statutes the people have power to make the rules, customs, and regulations of the free occupancy of the public land for exploration for minerals, what they please. The courts enforce the rules, customs, and regulations when created by the people interested. If the people of a mining district or locality consider that lode claims in that locality or district should not be more than 1000 ft. along the vein and not more than 100 ft. wide on each side of it, they can adopt rules and regulations fixing these maximum dimensions for the location of claims in the district thereafter, and thereby make them the law of the district which the courts will enforce. If the people in the mining territory consider that 20 acres is too much to be embraced in a single placer claim occupancy, they may make rules and regulations limiting the extent of the claims to 10 acres, to 250 ft. sq., or to any other dimensions they elect as most likely to provide for the best interests of people in that district. The people may make rules and regulations for their district requiring \$200 value of work on each claim annually or requiring a still larger sum, or requiring continuous work, and the rules and regulations they made would be the law of assessment work for all mining claims in the district beginning with the next succeeding January 1, whether claims were located before or after the adoption of the rules and regulations. If the people consider that it is to their best interests that lode claims in their district should not have extralateral rights, they may make rules and regulations of lode mining claims which limit them to their side boundary lines. Such rules and regulations would not affect the extralateral rights attached to claims located prior to the adoption of the rules and regulations. These would be vested and existing rights which would be recognized. But locations made subsequent would not carry extralateral rights, and that is all the substantial difference which would be made by a change in the present United States statutes.

Rules and Regulations v. Custom

What has happened, however, is that the people have permitted a miners' custom to take the place of their miners' rules and regulations. It has become the very general custom of miners in all the mining districts to initiate exclusive occupancy of the land and to maintain it under the express limitations made in the statute. Locations of mining claims are made in extent up to the maximum permitted by the statutes and are held by performance of the minimum value of annual work, \$100, named in the statutes. It has been very generally forgotten that the acceptance of these respectively maximum and minimum statutory limits for location and holding of mining claims are mining customs, and that they have force as law because they are the mining custom of the people of the several districts, and not because they are mandatory requirements by reason

of being made so by express statutory provision. It will suggest itself at once in confirmation of this statement that it is the fact that for many years up to a maximum of 18 years before there were United States mining statutes, there were many different district rules and regulations, all of which were law, and that in some of the older districts the rules and regulations were already beginning to be replaced by mining customs. The enactment of the statutes did not destroy the force of the district rules and regulations, or the mining customs where they were within the limits made by the statutes. The statutes neither enlarged or cut down the extent of claims existing when they were enacted. They did not reduce the requirement of annual work where it was more by the rules and regulations than the \$100 minimum named in the statute, but increased it to \$100 where rules and regulations or custom exacted less. It would be difficult to find among the thousands of mining districts any in which the rules and regulations were regularly amended to conform to the provisions of the statutes. The miners' rules and regulations gradually faded away into the miners' customs and the latter, developing on the line of least economic resistance, became identical in requirements with the United States statutes.

Right of the People to Make Rules

A custom can always be changed. The lawful right of the people of a mining district to change their mining customs by substituting mining rules and regulations which suit their circumstances better, is still theirs. No amendment of the United States statutes has been made taking this vital law-making right away from the people. And, in this connection, it should not be overlooked that it is the people—all the people—of a mining district, who make its rules and regulations, and not the lesser number who are the claim owners. The people of a mining district have the power to make rules and regulations for assessment work which will compel claim owners to work their claims or abandon them to new owners who will work them. It is impossible for claim owners to 'hog' possession of mining ground without doing any work on it, if the people want to prevent them from doing it.

What is there really wrong in the conditions of occupancy of public land for exploration of minerals under the provisions of the existing statutes, which has suggested the need of their revision as the means of righting the wrong? If the people of the mining districts have the full legislative power to make the mining law of occupancy of the public land between themselves, what seems best for themselves what more can be wanted by them and why? The answers to these questions develop the real trouble of the mining industry on the public land. Considering the matter historically, it will be found that, prior to the middle nineties, while questions growing out of extralateral rights and the amount of annual assessment work were more or less disturbing locally in the mining districts and among people interested in the mining industry, there was no outside interference with the law of occupancy of the public land for purposes of exploration for minerals. The free mining in the public land was let alone by people not

engaged or directly interested in it. None of the particular questions concerning mining in the public land which are now subjects of general political discussion were mentioned during the nearly fifty years of mining which preceded the middle nineties. They came afterward and from the outside.

Rent of Mineral Land

The proposition that rent should be paid the federal government for the exclusive occupancy of public land for purposes of exploration for minerals comes from outside the people of the mining industry. But why should the federal government collect rent from miners more than from farmers who settle on the public land to homestead it into a free fee title? Why should there be discrimination? And why should anybody pay rent at all to the federal government? The people are sovereign and as sovereign own the soil of the public land. The federal government is simply the general agent of all of the people. The idea of all of the people paying rent to themselves is absurd. If paid only by miners to the agent of all the people as compensation for the agent's services to all the people, the rent unquestionably becomes an unequal and unlawful tax. Calling the money which would be paid by some other name does not change its essential nature as rent for occupancy of public land, whether the occupancy be by miners or by farmers. It is, no matter how named, a federal tax which is both unfair as between fellow citizens and unconstitutional under our mode of government.

In one of the disguises of another name which the rent-payment proposition has taken, it is proposed that instead of a minimum requirement of \$100 annual assessment work to hold exclusive occupancy of a mining claim, that the \$100 shall be paid to the federal government as a license fee for the occupancy, on the ground that the \$100 annual assessment work is usually wasted in digging a hole in the ground, or in other ways, producing nothing in return for the expenditure. The conclusive answer to this is that the \$100 expended in the assessment work, no matter what it does to the claim or for the claim owner, contributes to support a free working man and to maintain a population in the district where the claim is situated, while \$100 rent paid the federal government only contributes to support one more politician in idleness in some great centre of population and pleasure.

Discovery Rights

Another trouble with occupancy of the public land for purposes of exploration for free minerals has been a supposed requirement of the statutes that a discovery of the mineral was requisite to make an exclusive occupancy for purchase or exploration for minerals lawful. As a fact, the United States statutes make no such requirement. The requirement made by the statutes is that the discovery of the 'ledge' or vein of quartz, that is to say, of the lode, must be made before a claim is made by location to exclusive occupancy of public land for exploration for minerals in a lode. The reasons for this requirement is very plain. Such occupancies are granted extralateral rights for the lode, and the width of

the land occupied is measured from the line of the lode. Obviously without the lode being discovered there is nothing to measure width from, and nothing to which to attach extralateral rights. The requirement of the statute that there shall be a lode discovered before location does not mean that mineral shall be discovered in the lode before a lawful location could be initiated. Lodes are located on the assumption that exploration in them will discover mineral even where there is none in sight. On the other hand, the mineral from a lode is frequently found in the 'float' or loose surface rock and earth without the lode itself being found, yet, while the mineral is certainly lode mineral, no lode location can be lawfully made. There is no requirement in the statutes that there shall be a precedent discovery to make a lawful claim of occupancy of public land as placer. The location of a placer claim is primarily made to obtain an exclusive occupancy before spending time and money in exploring in the land to make a discovery of the mineral. This condition of placer location was well understood by the old miners and was everywhere recognized by the rules and regulations which they made for locating placer claims. It is invariably the custom now when a new mining district is developed for locations of claims of exclusive occupancy to be made first, exploration in them to discover the mineral coming afterward.

Exclusive Occupancy Under Miners' Rules

The statutes not only in express terms confirm and recognize the practice or custom of the miners in this matter of establishing an exclusive occupancy of the public land under miners' rules and regulations before they undertook to explore and make discovery of the minerals, but the provisions of the statutes themselves relate to locations of claims of exclusive occupancy of public land for mining purposes, and do not relate to the making of discoveries of minerals. The statutory provisions are consistent without extending them by implication of anything not expressed in direct words. The statutes grant free minerals to the finder, and grant free occupancy for the purpose of finding the minerals. It is only occasionally that the minerals are discovered without digging into the surface of the earth to find them. The proposition that the free minerals must be discovered before there can be a right to free exclusive occupancy has no basis in public interest—in fact, it is the other way. The requirement of prior discovery before a right of occupancy can be initiated works out practically to limit and discourage exploration by making its reward uncertain. The proposition that a discovery of minerals was a necessary precedent to a lawful mining claim did not originate with miners' rules and regulations, nor from courts deciding controversies between rival claims of miners. Some recent decisions of the courts where the good faith of the mining location was questioned have indicated that a discovery of the mineral was necessary to make a location lawful, but the great mass of court decisions, where the good faith of the location was not in issue, are in line with the letter of the statutes in confirming rights of exclusive occupancy for purposes of exploration without there being a precedent discovery of the mineral.

The Rand Banket and Its Gold Content—II

By C. B. HORWOOD

Today the quartzites and conglomerates of the Witwatersrand beds form an almost impervious mass,⁴¹ owing to the action of dynamic metamorphism and the deposition of secondary silica and, to a less extent of pyrite and other secondary products in the interstices of the original sandstones and conglomerates. Pressure exerted in a north and south direction has bent and folded the beds into their present position. The main structural features of the district indicate that this pressure was due to the intrusion of enormous masses of Ventersdorp diabase, accompanied by considerable fracturing, faulting, and consequent intrusions of diabase dikes.⁴² Thus, deep-seated communications were established; and solutions, ascending from great depth through fractures and along lines of weakness marked by the intrusion of dikes, would at the time have encountered the beds in a sufficiently pervious condition to penetrate them. The conglomerate beds naturally formed lines of least resistance to the passage of solutions; and thus some of them became channels of maximum circulation. Along the Crown Reef dike, the evidence indicates that the mineralizing solutions, which deposited the iron bi-sulphide and gold, ascended along the line of fracture and weakness produced by the intrusion of the dike, and spread out laterally near the surface, choosing one or more of the conglomerates as offering the easiest channels.⁴³ Combined with their lateral motion they would also have had a downward component due to gravity. As previously mentioned, the Main Reef Leader here immediately overlies a band of shale. The latter is fine and close-grained, with laminae parallel to the dip of the conglomerate. It thus forms an almost impervious layer; and so it is an easy matter to understand how mineralizing solutions would have become concentrated above this layer, and have precipitated some of their contents along its junction with the overlying and more porous conglomerate, especially as here the rate of flow would have been lessened owing to the fact that the downward component of motion would have been checked. (This explains why a thin film of pyrite or of gold is frequently found on the upper surface of the foot-wall of a rich leader, when this

foot-wall consists of shale, or is talcose, or has suffered much sericitization.) If this actually happened, one would expect to find the majority of the pyrite 'pebbles' along a definite horizon⁴⁴ at or near the immediate contact of the conglomerate with the underlying shale, and if there were any above this, that they would be less in number. This is how they actually did occur; and no pyrite 'pebbles' were found below this shale band. Also, one would expect to find that here this blanket layer was rich in gold; and it was, as this stope was one of the richest places in the mine;⁴⁵ and nearly all the gold was contained in that narrow band of conglomerate in which the pyrite 'pebbles' occurred.

Association of Pyrite 'Pebbles' with Dike Intrusion

Thus the association of pyrite 'pebbles' with dike intrusion and rich ore⁴⁶ was one of the most notable features of this occurrence at the Crown Reef mine.

As a result of examining numerous slides of the pyrite from this occurrence, the writer found that while some of the 'pebbles' certainly have replaced real quartz pebbles, others have replaced the quartzite matrix of the blanket. Fig. 5 and 6 are microphotographs of sections cut through pyrite pseudo-

⁴⁴The flint nodules in the chalk beds of England usually occur along horizons coinciding with the bedding-planes of the chalk, these having formed the easiest channels for the circulation of the silicious solutions. But it is only fair to remark that, probably, in some cases the explanation is also partly due to certain layers in the chalk having originally contained more silicious organisms, such as sponge spicules. In the case under discussion the horizon was fixed by the presence of an underlying, almost impervious, band of shale. There is distinct evidence all along the Rand of secondary enrichment, both in and below the oxidized zone, due to the action of meteoric waters. As there is, however, in this case at this depth no evidence of such secondary gold and sulphide enrichment, the latter is evidently entirely due to the causes above explained. (For treatises on the subject of secondary enrichment, the reader is especially referred to 'The Secondary Enrichment of Ore Deposits,' by S. F. Emmons, and 'The Formation of Bonanzas in the Upper Portion of Gold-Veins,' by T. A. Rickard, both in 'The Genesis of Ore Deposits,' 2nd Ed. (1902), published by the Am. Inst. Min. Engineers.)

⁴⁵For the last nine months of 1905, the value of this stope averaged 22.8 dwt. over about 21.25 in. of reef, or 12.4 dwt. over a stoping width of about 39 in., and for the first six months of 1906 it averaged 20 dwt. over 22.5 in. of reef, or 10.7 dwt. over a stoping width of about 42 in. These values were nearly all obtained in the narrow band of Main Reef Leader conglomerate in which the pyrite 'pebbles' occurred; for example, during the first six months of 1906 the Main Reef Leader averaged 41.6 dwt. over 9 in., while that portion of the underlying Main Reef which was stoped, and which was separated from the Main Reef Leader by a narrow, almost impervious, band of shale, only averaged 5.4 dwt. over 13.4 in., the two together thus averaging 20 dwt. over 22.3 in. of reef. The average stope assay for the period was 10.7 dwt. over 42 inches.

⁴⁶Rand ore, or, in other words, the auriferous conglomerate of the Rand, is relatively poor compared with the ore of other goldfields; but this is compensated by the comparative uniformity of its yield over big areas. Speaking generally, assays of 8 dwt. and upward, over say 36 in., would on the Rand be considered good.

⁴¹ This is evident from the fact that while the original shallow outcrop mines of the Rand are wet, the deep-level mines are dry and dusty, the dryness increasing with depth.

⁴²C. B. Horwood (1905, *loc. cit.*, p. 35; and (1910) *loc. cit.*, p. 76; and 'Notes and Analyses of Typical Transvaal Rocks,' by C. B. Horwood, *Trans. Geol. Soc. So. Af.*, Vol. XIII (1910), pp. 42 and 43.

⁴³The fact that some of the conglomerate beds contain gold in sufficient quantity while others contain little or none seems to be considered by many a serious difficulty in explaining the genesis of the Rand gold. Apparently, they forget that, although often far more difficult to explain, it is quite usual to find poor or barren, quartz, veins in the neighborhood of, and often parallel to, rich ones. So that this is merely a still further analogy between the Rand bankets and ordinary gold-quartz veins.

morphs after quartz pebbles. (As the slides were photographed by transmitted light, the pyrite comes out black in the photographs.) In the former, the large 'pebble', extending from the centre to the top of the photograph, is composed of iron pyrite; and in the slide the mosaic crystalline structure, so char-

FIG. 5. SLIDE 63.

acteristic of the quartz pebbles of the Rand banket, has not been obliterated, but is clearly discernible with a 2-in. objective. The retention of this original structure by the replacing of material is clear evidence that it has replaced one of the quartz pebbles of the banket.⁴⁷ The 'pebble' has a smooth and well defined outline, with the exception of that portion extending from about one-third of the way up the left side to the small slit at the top. This latter portion, stretching inward for about $\frac{1}{4}$ in.

the matrix of the conglomerate. The outlines of the quartz granules of which the latter was composed can readily be distinguished under the microscope. The white portion, marked A, stretching between the lower end of the pyrite 'pebble' and the partly formed one below it, consists of secondary fibrous quartz, the fibres radiating outward from the circumference. Fig. 6 is also of a pyrite 'pebble' formed by the replacement of a quartz pebble.⁴⁸ Again, in this slide, the outline of the individual crystals composing the original quartz pebble have not been obliterated and can be distinctly seen with a low-power objective. Numerous particles of unreplaced quartz are enclosed in the pyrite. The white streaks running through the 'pebble' consist of secondary quartz, with a tendency to fibrous structure, which has been introduced along cracks evidently produced after the pyrite was formed. Fig. 7, 8, and 9 are micro-photographs showing pyritic replacements of the matrix. The first of these shows, not a formed pyrite 'pebble', but merely a mass, or agglomerate, of pyrite, which, from its structure, distribution, shape, and tendency to form crystalline outlines,⁴⁹ has apparently replaced the small quartz granules and interstitial matter of the matrix. In one place this mass of pyrite is seen embaying and eating into a rounded quartz pebble, the pyrite apparently replacing matrix and pebble indiscriminately. The white portions seen in the photograph, running through the pyrite, consist of secondary fibrous silica, the length of the fibres being at right angles to its walls; that is, at right angles to the cracks or fissures, or to the bounding edges of the pyrite. As in the case just cited, it undoubtedly fills cracks made in the pyrite 'pebble' after its formation. These cracks, as we shall see later, were due to contraction. The direction of

FIG. 6. SLIDE 59.

FIG. 7. SLIDE 58.

as measured on the photograph, consists of pyrite that has evidently replaced the quartzite matrix, as the granular structure of the latter can be clearly seen under the microscope. The small round pyrite 'pebble', seen about half way up on the right-hand side of Fig. 5, has been formed by replacement of

the tensile stresses so produced is doubtless indi-

⁴⁷The section has been broken in mounting. The pyrite in the two portions should, of course, be continuous in outline.

⁴⁸From macroscopical and microscopical study of the subject, the writer found that pyrite which has partly replaced a pebble metasomatically usually tends to conform to the shape of the latter rather than to assume crystalline outlines; whereas the secondary pyrite, which has replaced a portion of the matrix, is often in the form of either cubes or octahedra.

⁴⁹Lindgren has recently remarked on the fact that in metasomatic replacements the "structure and texture are often faithfully preserved." ('The Nature of Replacement,' by W. Lindgren, *loc. cit.*, p. 535.)

eated by the direction of the fibres of this secondary silicea. Fig. 8 shows three aggregates of pyrite formed by the replacement of the matrix. The outlines of the original quartz granules have not been obliterated, and are distinctly observable in the

masses represent a more advanced stage in the formation of 'pebbles' than that shown in the previous photograph; they are more compact and their edges are better rounded and defined. It will also be observed that, in section, they have assumed a cir-

slide, when examined under a low power.⁵⁰ Secondary fibrous quartz can be seen along the right edge of the central pyritic mass. These three pyritic

⁵⁰The shape and outlines of the original quartz granules of the matrix are particularly well preserved in the case of the centre one of the three pyrite aggregates. They are best examined by reflected light, either under the microscope or with a powerful pocket lens.

cular or oval shape, doubtless due to fairly uniform growth on all sides. It will be noticed that the quartz pebble in the lower right-hand portion of the photograph has its edges embayed, eaten into, fretted, and corroded by pyrite. The top edge of this pebble has been partly dissolved and has been drawn out into wavy streaks; and the portions between the streaks have been filled with secondary

silica and some pyrite. Fig. 9 is a section cut at the contact of the Main Reef Leader with the underlying shale; it shows a well formed oval⁵¹ pyrite 'pebble' with a well defined smooth outline, which one might easily take to be a pseudomorph after a quartz pebble; but when examined in thin section under the microscope, the writer found that outlines of the quartz granules of the matrix could be clearly seen, the original structure having been retained, proving it to be a replacement of the quartzite matrix. The secondary fibrous growth seen around a portion of this pebble appears to be a mixture of chlorite with some quartz and minute specks of pyrite. At A, some unreplaced quartz is seen enclosed in the pyrite 'pebble'. At B, there are some small cubes of pyrite which have replaced a portion of the matrix. Many of the quartz crystals exhibit corroded outlines and slight strain shadows.

Fig. 10 is a photograph of a good typical speci-

FIG. 11. PYRITE 'PEBBLES' SHOWING RADIAL STRUCTURE, IN MAIN REEF LEADER.

men of Main Reef Leader, about 3 in. wide, resting on a shale foot-wall. It is from the Crown Reef mine, from the stope where the 'pebbles' occurred, and was taken about 100 ft. up the stope, away from the dike contact, where its influence was less, and so the pyrite 'pebbles' are small and scarce, only two tiny ones being seen in the plate.

Fig. 11 shows a polished surface of banket resting on a shale foot-wall, and cut through four pyrite 'pebbles'. Two of the latter exhibit a well marked, internal, radiating structure. Only some of the pyrite in this Crown Reef exhibits this structure, but there can be no doubt that the 'pebbles' have all been formed in the same way. It would seem that it is a later superinduced development. It may be a result of molecular rearrangement, due to gradual contraction. It is certainly, in some way, connected with the origin of the 'pebbles' and is in itself a sufficient indication that they were formed in place, and are not rolled pebbles. This subject will be more fully discussed later.

The Du Preez Series

Perhaps the best known example of the occurrence of pyritic 'pebbles' in the banket is that of the

⁵¹That is, the section of the pebble is oval shaped. The pebble itself is in the form of an ellipsoid.

small rounded pellets of pyrite in the Du Preez series at the New Rietfontein Estate mines.⁵² These 'pebbles' vary from about $\frac{1}{8}$ up to $\frac{1}{4}$ inch in diameter; occasionally one nearly half an inch can be found. They are almost entirely confined to one particular member of the conglomerate series, which, owing to the supposed resemblance between these pyrite pellets and ordinary buckshot, is known as the Buckshot Reef. This banket has already been described by the author in another place;⁵³ but, for the purpose of the present paper, a further brief description is necessary. It is a small leader occurring at distances varying from a few inches to more than a foot below the principal gold-carrier or 'pay-reef'⁵⁴ of these mines, and is only present in their western portion. As typically developed, it consists of a single-pebbled layer, with white lustrous rounded ellipsoidal quartz pebbles, of which the largest vary from about an inch to an inch and a half in greatest diameter; and fewer and rather smaller black quartz pebbles. These pebbles all lie with their longer axes parallel to the dip of the bedding. Instead of a single-pebbled 'leader,' it is sometimes from two to four inches thick. Again, it may contain no pebbles at all, or only minute ones, and merely be represented by a line, usually of carbon⁵⁵ accompanied by visible gold. As in the Crown Reef mine, so here the pyritic 'pebbles' occur most abundantly along the immediate foot-wall portion of the conglomerate, and diminish in number upward as the distance from the foot-wall increases. The reason for this is doubtless the same as that advanced in the previous case, for this bed of conglomerate has a greasy talcose foot-wall, the laminae of which are parallel to the bedding-planes, or dip of the banket, and it would therefore present an impervious layer to solutions circulating above it. On a fractured or polished surface of one of these pyrite 'pebbles' a radiate and fibrous structure can often be seen; sometimes a concentric structure is exhibited; and the author has also noticed a stratified appearance. Carbon is asso-

⁵²As already stated, these mines are situated about nine miles east of Johannesburg, and about four miles north of Germiston.

⁵³'The Mode of Occurrence and Genesis of the Carbon in the Rand Bankets,' by C. B. Horwood, *Trans. Geol. Soc. So. Af., Vol. XIII* (1910).

⁵⁴The Pay Reef is also the name by which this lode is known at the Rietfontein mines.

⁵⁵The carbon usually occurs in small black opaque nodular grains, having a somewhat warty dull surface, and ranging in diameter from 1 mm. downward. 'Further Notes on the Auriferous Conglomerates of the Witwatersrand, etc.,' by R. B. Young, *Trans. Geol. Soc. So. Af., Vol. XII* (1909), p. 86.

Vide, also, C. B. Horwood, *loc. cit.* In this paper the present writer showed that the carbon in the bankets is due to magmatic vapors or solutions derived from the neighboring basic dikes before their final solidification; and he proved by numerous analyses that these dikes contain carbon. It was also shown by him that the occurrence of carbon was so closely associated with that of the pyrite and gold as to leave no doubt that there was a genetic relationship between all three of them; and this relationship was still more fully emphasized in a more recent paper entitled 'Iridosmine from the New Rietfontein Mines; Its Occurrence, Analysis, and Genesis,' *Trans. Geol. Soc. So. Af., Vol. XV* (1912).

ciated with this 'reef' and occurs in tiny specks on the surfaces of the pyrite 'buckshot' and also scattered through the matrix. The Buckshot Reef is characterized by high gold contents. At the surface the pyrite pellets weather to a black oxide, and their usual radiate habit is then well marked; sometimes the black oxide has been dissolved, and only the casts and the internal radiating divisional walls of secondary silica are left. On the inside surfaces of these casts, specks of carbon and free gold are often visible. Fig. 12A, 12B, and 13 are from photographs of two typical hand specimens of this 'reef.'⁵⁶ In the case of each of these specimens the surface that showed the 'buckshot' pellets best was ground and polished, in order to obtain a better photograph. On the left-hand and near the top of Fig. 12B, a complete circular section of one of these can be seen, exhibiting radiate structure. To the right of this the pyrite pellets have come out white, owing to the reflection of the light from their polished surfaces, but the annular rings, or partial ones, as the case may be, around some of them, can be detected. These rings, which can be well seen in the hand specimens by the aid of a good magnifying glass, consist of the secondary fibrous silica to which attention has already been directed.

Presence of Gold Around Pyrite Pellets

Fig. 12A is from another photograph, of the same specimen, taken in diffused light, so as to avoid the reflection from the polished pyrite surfaces. In some instances in the hand specimens visible gold can be seen round the circumferences of the pyrite pellets, and specks of carbon occur scattered through this gold ore.

Fig. 14 shows a micro-photograph of a thin section cut from a specimen of the Buckshot 'reef.' The round black spots represent the pyrite 'pebbles', and in this lode their spherical nature and smooth surfaces are particularly characteristic. When examined under the microscope with a 1-in. objective, the quartz pebbles are seen to be embayed in places by pyrite. Numerous minute, sharp, angular fragments of quartz still remain unreplaced here and there in the pebbles. This can be seen in one of the 'pebbles' in the photograph. In some, a radiating structure is apparent under the microscope, the lines radiating outward from the centre of the pebble. They usually have a secondary growth of crystalline fibrous quartz, also radiating outward around portions of the circumferences. Gold is visible in places around the edges of the pebbles. In the particular slide shown in Fig. 14 the process by which these buckshot pebbles were formed in place can be traced. The pyrite replaced some of the quartz of both the coarse and finer particles constituting the matrix of the conglomerate. In some cases not only the dark outlines of the original quartz particles and granules, but also the mosaic structure of the larger quartz particles, the division between individual crystals, and the original dusty-looking lines of inclusions running through the quartz have not been effaced by the

replacement of the original substance by the pyrite, and are still quite distinct under a low-power objective. The quartz and pyrite are sometimes agglomerated as a confused mass—the pyrite having so far only replaced a portion of the small quartz granules of the matrix, as at A in Fig. 14. This constitutes one of the transitional forms of the process of replacement. Eventually all, or nearly all, the associated quartz is replaced, and a compact mass of pyrite results. The spherical shape is doubtless due to fairly even growth around a centre; and the particularly spherical nature of the iron bisulphide pellets in this occurrence suggests that there was no rapid lateral circulation of the precipitating solutions. The more ellipsoidal shape of the Crown Reef pyrite 'pebbles', on the other hand, and the fact that their longer axes are parallel to the bedding, shows that deposition has been greater along the direction of the bedding-plane than at right angles to it, and indicates a fairly strong lateral flow of the solutions through the bedding-planes of the banket.⁵⁷ This subject will be discussed more fully later. The central portion of the slide (Fig. 14) is cut through a well rounded quartz pebble of about the same size and shape as the pyrite 'pebbles', which suggests that the latter were pseudomorphs after quartz pebbles. Some of them evidently are, as the structure of the original quartz pebbles is, in some instances, still sufficiently discernible under the microscope, but probably the majority represent replacements of the matrix. Secondary pyrite can be seen in the central portion of this particular quartz pebble and also in the irregularly shaped quartz pebble just below it, and may represent the initial stages of replacement. Posepny has already pointed out that many phenomena in the formation of pseudomorphs are hard to explain, and gives as an example the fact that in some minerals the change commences within the mass and progresses outward; and, as he states, where the original substance was expelled there must have first been access for the liquids that began and executed this effect; such may be furnished by original minute rock-cavities, or by secondary cavities.⁵⁸ In the case under discussion there appear to be no secondary cavities, or cracks, by which the liquids could have entered, unless, which is probable, they worked their way along the junctions between the individual crystals of which the pebble is composed; also, minute cracks may formerly have existed, as under the microscope the quartz shows undulose extinction, indicating that it has been subjected to strain, and the slide exhibits distinct signs of shearing. The numerous small granules of pyrite seen scattered through the slide have mostly been formed by replacement of

⁵⁶They are best seen with the aid of a good magnifying glass.

⁵⁷This is what one would expect in that particular case, as the 'pebbles' occur so close to the soft decomposed face of an almost vertical dike, that is, near to one of the main channels whence the circulating solutions arose; for, presumably, it was up this plane of contact that some of the mineralizing solutions ascended from great depth, and then spread out laterally. The decomposition of this face of the dike is doubtless due to the action of these same solutions.

⁵⁸'The Genesis of Ore Deposits,' by F. Posepny, 2nd Ed. (1902), p. 15 (published by the Amer. Inst. Min. Engineers).

quartz granules of the matrix. There appears to have been a distinct tendency for pyrite to form around the edges of the pyritic masses already formed.⁵⁹ This can be seen at C (Fig. 14) where four small particles of pyrite have been formed at one end of a larger pyritic mass and two small ones at the other end of it.⁶⁰ The frequent growth of secondary fibrous quartz around the edges of the pyrite 'pebbles', as at B, suggests that the pyrite

described a slide of blanket from these mines, the section exhibiting an irregular fragment of such striped slate, which has been completely pseudo-morphed by pyrite and in which the banding is perfectly preserved. He describes the material of the pebble as banded slate of the Hospital Hill⁶² type, and expresses his opinion that the banding is due to minute inclusions in the quartz of the original rock that have remained enclosed without

FIG. 12A. BUCKSHOT REEF FROM RIETFONTEIN ESTATE MINES.

FIG. 12B. BUCKSHOT REEF FROM NEW RIETFONTEIN ESTATE MINES.

in such cases now occupies less room than did the quartz it originally replaced.

Angular and Sub-Angular Pebbles

In addition to the 'buckshot', other pyrite 'pebbles' occur at the Rietfontein mines. Angular and sub-angular pebbles of black or dark banded slate, which has been much altered and indurated and is often of cherty appearance, and might perhaps be better described as lydian stone, can frequently be

change of place in the replacing material. The banded appearance of this particular type of slate has, however, been shown, and generally accepted, to be due to variations in texture and relative proportion of quartz grains, such as might be expected

FIG. 13. BUCKSHOT REEF FROM THE NEW RIETFONTEIN ESTATE MINES.

FIG. 14. SECTION OF BUCKSHOT REEF FROM THE NEW RIETFONTEIN ESTATE MINES, SHOWING PYRITE PEBBLES. SLIDE 57.

found in almost all stages of replacement by iron bisulphide. In these cases the pyrite has worked in along the original bedding-planes of the slate, of which the pebbles are composed, and in consequence has often produced a banded appearance, or accentuated such if already present. R. B. Young⁶¹ has

to occur under conditions of sedimentation from currents.⁶³ This so-called slate is more of a quartzite, not only as regards structure, but also in chemical composition, for the proportion of alumina pres-

⁵⁹In an article entitled 'Progress in Chemical Research,' in the *Mining and Scientific Press* for Feb. 15, 1913, the fact was emphasized that crystalline substances have a strong tendency to be deposited on crystals of the same substance if present.

⁶⁰This is best studied by using a magnifying glass.

⁶¹'Notes on the Auriferous Conglomerates of the Witwatersrand,' by R. B. Young, *loc. cit.* (1907), p. 25.

⁶²The Hospital Hill slates form a very well known and conspicuous member of the Lower Witwatersrand beds.

ent is far less than in a true slate.⁶⁴ The writer was at one time assistant general manager of these mines and is therefore well acquainted with the occurrence of these pebbles. He particularly noticed the frequency with which they have been replaced by pyrite, whereas pebbles originally of quartz that have been replaced by pyrite are of much rarer occurrence.

Replacement by Pyrite

A splendid example of a hard black cherty-looking pebble partly replaced by pyrite, which has worked in toward the centre from the outside, was found by the writer in 1907 in the Pay Reef in one of the stopes in the western section of the New Rietfontein mines. The portion of the banket in which it occurred consisted of a good specimen of the Pay Reef, and to avoid injury it was carefully chiseled out of the face of the stope. It contained white rounded quartz pebbles up to about $\frac{7}{8}$ inch in greatest diameter, and a few small buckshot 'pebbles' up to about $\frac{1}{8}$ inch in diameter, which were scattered along, and just above, a sericitic foot-wall. Under a strong magnifying glass the structure of these small 'pebbles' could be seen well. In some of them the process of formation was incomplete; these consisted of heavy rings of pyrite around central cores. The latter were apparently composed of the original banket matrix, which was only partly replaced by pyrite. Presumably, the outer rings of pyrite already formed had effectually closed the pores and prevented the further entry of solutions to the central portions. No free gold or carbon could be discerned. The writer wished to see whether this specimen confirmed his usual practical experience that such 'pebbles', whether wholly or only partly replaced by pyrite, are an indication of good ore. Therefore he had it carefully cut in two by means of a rock-sectioning machine, so as not to run any risk of injuring the portion containing the partly replaced pebble. The larger portion was assayed and found to contain 43 dwt. of fine gold per ton; thus corroborating his former experience. The surface of the smaller portion,⁶⁵ which contained the partly replaced pebble, was ground and polished, and is illustrated in Fig. 15, from which it will be seen that the section of the partly-replaced pebble is oval, or rather pear-shaped, and that it has a smooth outline. The portion replaced by pyrite is white in the figure, owing

to the reflection of the light, when photographed, from the highly polished surface of the pyrite. The outer edge of the pebble has been replaced by iron bisulphide, and from the inside of this layer, or outer shell, little tongue-like growths of iron pyrite can be seen projecting inward toward the centre of the pebble. This transitional form has been preserved in this stage of development owing, doubtless, as in the cases just cited, to the growth of the pyrite from the outside having been so compact, and also sufficiently soon consolidated, to have entirely closed up all pores or channels by which further pyrite solutions might otherwise have penetrated and replaced the central portion of the pebble.

The Crown Reef Mine

At the Crown Reef mine the pyrite 'pebbles' were associated with good ore in the immediate

FIG. 15. THE PAY REEF, NEW RIETFONTEIN MINE. SHOWS BLACK PEBBLE BEING REPLACED BY PYRITE. SLIGHTLY ENLARGED. A, BLACK PEBBLE BEING REPLACED BY PYRITE. THE LIGHT-COLORED OUTER PORTION IS PYRITE. B, GLOBULAR AGGREGATE OF PYRITE.

neighborhood of a well defined, persistent, decomposed diabase dike, the formation of the pyrite being evidently associated with the igneous intrusion. At the Rietfontein mines, where the pellets of pyrites are a characteristic feature and are also associated with good ore, and where other pyrite 'pebbles' are also found likewise associated with good ore, there are strong decomposed diabase dikes, 80 to 120 ft. thick, which occur throughout the entire length of the mines, that is, for a distance of nearly two miles. The occurrence of these pyrite pellets is closely associated with the presence of carbon, and it has already been shown that there is a close relationship between the deposition of the latter and the intrusion of these dikes.⁶⁶

When afterward manager of various gold mines at Randfontein,⁶⁷ the writer continued his investigations of these replacement 'pebbles.' Fig. 16 shows a typical rich specimen of the Randfontein Leader.⁶⁸ The rounded light-colored pebbles consist

⁶⁴For chemical analyses of Hospital Hill slate, see G. Denny, *Jour. Proc. So. Af. Assn. Eng.* (1904), Vol. II, No. 4, also, 'Notes on the Chemical Composition of the original quartzite of the Hospital Hill', J. H. P. Horwood, *Trans. Geol. Soc.* Also, for analyses of division between individual crystalline beds, 'Notes and final dusty-looking lines of inclusion', Horwood, through the quartz have not been effaced by

⁶⁵They are best seen with the aid of a good magnifying glass.

⁶⁶'The Mode of Occurrence and Genesis of the Carbon in the Rand Bankets,' C. B. Horwood, *loc. cit.* (1910).

⁶⁷On the Far West Rand, about 27 miles west of Johannesburg.

⁶⁸This corresponds to the South Reef Leader of the

of light-gray quartz. The big angular pebble on the left is one of those compact and indurated cherty pebbles similar to those already described as occurring at the New Rietfontein. They are frequent in the ore of the Rand, and are occasionally partly replaced by iron pyrite, and they are often found in the Randfontein Leader. Only occasionally do they occur in the West Reef,⁶⁰ and in this

of the Lower Witwatersrand formation; and to be, as already mentioned, really fine-grained quartzites containing a small proportion of aluminous matter, rather than true slate. About one-half of the angular pebble in Fig. 16 has been replaced by iron pyrite, which has evidently worked its way in along the original lines of stratification, still distinctly visible in the pebble. These pebbles, also, are asso-

FIG. 16. RANDFONTEIN LEADER, SHOWING ANGULAR BLACK PEBBLE BEING REPLACED BY PYRITE. THE BROKEN BLACK LINE INDICATES A LINE OF VISIBLE GOLD ALONG THE FOOT-WALL. case also they are sometimes partly replaced by iron pyrite. Numerous sections of such pebbles were examined under the microscope by the writer and found to be similar to sections of the so-called slates

Central Rand. As typically developed, the Randfontein Leader series consists of three thin beds of conglomerate. The uppermost, or hanging wall 'reef,' varies from about 8 up to 18 in. thick, and is usually too poor to work. Some 6 to 18 in. below this, and separated from it by quartzite, is the Middle 'reef.' The thickness of this varies from about 4 to 10 in. It frequently contains a profitable amount of gold and is often mined with the Leader, which is the productive member of this series, and is the lowest of the three 'reefs,' being separated from the Middle one by some 4 to 10 in. of quartzite. It varies from a mere streak up to 4 to 6 in. thick. Perhaps, as most typically developed, it consists of a single line of pebbles, varying in greatest length or diameter up to about $1\frac{1}{4}$ to $1\frac{1}{2}$ in. When a mere streak, its position is often fairly well marked by the contrast in color and texture of the hanging and foot-wall quartzite; the latter is softer, less crystalline, and lighter in color; as a general rule, it is sericitic, and white or light gray in color. A thin streak of gold, accompanied by minute specks of carbon, frequently occurs along the contact of the two quartzites.

⁶⁰The West Reef in the Randfontein mines corresponds to the Main Reef series of the Central Rand. It is separated by about 200 ft. of quartzites and a few intervening conglomerates from the overlying Randfontein Leader series. For a detailed description of the Leader and West reefs, with particulars of the pebbles, etc., occurring in them, see C. B. Horwood, *loc cit.* (1910), pp. 70-75.

ciated with good ore. In this particular specimen, for example, a heavy line of visible gold occurs along the foot-wall.

Fig. 17 is another specimen of Randfontein Leader. It shows two well rounded lustrous black quartz pebbles in different stages of replacement by iron pyrite, which has worked its way from the circumference. The one seen in the centre of the photograph presents an almost perfectly circular section, and around the circumference (with the exception of the top portion) there is a thin ring of pyrite which has replaced the outer portion of the pebble. The one above and a little to the right of this is of oval section; it has a much deeper border of pyrite, which all the way around, has replaced the outer portion of the pebble, the process of replacement in this instance having extended further than in the former case. The crystalline habit of the pyrite and the irregular manner in which the inner margins of the two rings have eaten toward the centres is particularly noticeable. It is perfectly evident that this pyrite was not present originally in the quartz far back in geological time, before it was denuded, transported, worn down into pebbles, and then deposited, with a vast number of others, to constitute those pebble reaches which now form the gold-bearing conglomerates of the Rand. Had it been, it would hardly have formed rings of

well defined pyrite crystals in such a manner that they now are coincident with the circumferences of the pebbles. Clearly these rings of pyrite have been formed by active solutions late in the history of the banket, by means of the simultaneous dissolution and replacement of the quartz of the pebbles.

Pyrite Aggregates

The most striking and characteristic replacement products of the Randfontein mines are small globular aggregates of pyrite and quartz granules.⁷⁰ They vary in size up to about $\frac{5}{8}$ inch in greatest diameter. In these mines the writer has found by experience that they, also, are infallibly accompanied by high gold contents. A good example of one of these globular aggregates is shown in Fig. 18, from a photograph of a specimen illustrating how the

FIG. 17. SPECIMEN SHOWING TWO BLACK PEBBLES IN DIFFERENT STAGES OF REPLACEMENT BY PYRITE. THE PYRITE IS SEEN TO BE PENETRATING FROM THE CIRCUMFERENCE. NATURAL SIZE.

Randfontein Leader sometimes shrinks from a single-pebbled banket into a mere line of visible gold accompanied by minute specks of carbon. In the centre, resting on the foot-wall contact, is one of the small globular aggregates above mentioned. The Leader is represented by this and by the gray quartz pebble to the right. To the left of the former, it is merely represented by the line of contact of foot-wall and hanging wall quartzites,⁷¹ along which gold and carbon are visible. The association of these globular aggregates with good ore is thus demonstrated in this instance by the presence of visible gold, and the latter is accompanied by carbon. Fig. 19 shows another specimen of the Randfontein Leader; it will be noticed that a slide has been cut from it through one of these pyrite aggregates in order to make a section of the latter for examination under the microscope. The pyrite aggregate is seen lying between two light-gray quartz pebbles, and it is embaying the edge of the one on the left. The association of these replacements

with good ore is again demonstrated by this specimen, as it contains visible gold, and the latter is again accompanied by carbon. From the section cut through this aggregate, and from other sections of them as examined under the microscope, the writer found that they consist of an intimate intergrowth of iron pyrite with the quartz granules and secondary quartz of the banket matrix, the pyrite having partly eaten into and replaced them in such a manner that a distinct graphic structure is sometimes developed. This structure seems to be due to the great tendency of the pyrite to form crystalline outlines. Fig. 20 is a micro-photograph of a portion of the slide cut from the specimen illustrated in Fig. 19; it exhibits this semi-graphic structure well, and also the strong tendency of the pyrite to form crystalline boundaries. It shows individual

crystals of secondary pyrite indiscriminately replacing both the granules of the matrix and the interstitial matter between them. As already pointed out in another place,⁷² these granular aggregates of quartz and pyrite evidently represent an intermediate stage in the formation of certain pyrite 'pebbles'; and, from examining sections under the microscope, it is apparent that the complete stages were: (1) The pyrite replaced the interstitial matter between the quartz granules of the banket matrix, and then the quartz granules themselves⁷³ (these two processes doubtless overlapping), until one of these aggregates had been formed; (2) the enclosed quartz and other matter was then replaced by pyrite, provided passages of entry were still open to the solutions, the pores

not having been plugged by the pyrite already deposited; (3) any rough outlines then became toned down and the pyrite aggregate, if not already a spherical body, became so by means of processes hereafter described.

The Randfontein Ore

As in the Crown Reef and Rietfontein occurrences, so also at Randfontein, 'pebbles' and globular aggregates of pyrite are closely associated with good ore and dike intrusions. Thus in the North Randfontein mine, where they are of particularly frequent occurrence, the West Reef is immediately overlain throughout its whole length, that is, for a distance of over 3000 ft., and along its dip for about 2300 ft.,⁷⁴ by an intrusive diabase dike.

This dike is known as the West Reef dike, and since it is probably the only one occurring in the mines of the Rand that has been studied in some detail,⁷⁵ a short description of it may not be out of place here, especially as, later on, this dike will be

⁷⁰The writer has already described the occurrence and origin of these globular aggregates, and pointed out that, in the Randfontein mines, where they occur, they are an infallible indication of good ore. *Loc. cit.*, pp. 73-75.

⁷¹Contrary to the general rule, the foot-wall quartzite is, in this particular instance, darker than the hanging wall quartzite.

⁷²C. B. Horwood, *loc. cit.*, p. 75.

⁷³From several points of attack.

⁷⁴As far as what was then (in 1910) the bottom of the mine.

⁷⁵The Mode of Occurrence and Genesis of the Carbon in the Rand Bankets,' by C. B. Horwood, *Trans. Geol. Soc. So. Af.*, Vol. XIII, pp. 71-72.

again mentioned and it will be shown that these strike-dikes have an intimate and important bearing on the genesis of the gold in the blanket. It is of a dull dark-gray color, and in the lower levels of the mine is fine grained, exceedingly hard, and dense. Numerous minute crystals of pyrite can be seen scattered through it in places, and it is traversed in all directions by cracks, presumably due to contraction on cooling. On both faces of these cracks a thin film, of carbonaceous appearance, which, however, does not always soil the fingers, is sometimes present; or, the cracks are often filled with minute seams of quartz; or sometimes contain films, or minute seams, of pyrite. Along its immediate foot-wall there is usually a thin seam, varying from less than inch up to two or three inches in thickness, or crushed material, or clayey decomposed dike, forming what, in Cornwall, is known as a 'flucan.' The West Reef is rather in actual contact with this or is separated from it by a few inches, varying up to 5 or 6 in., of dense pyritic quartzite, almost black in color and having an average gold content of about 3 dwt. per ton.⁷⁶ Between the reef and dike, and parallel to them, in or along the lower side of the clay selvage, a thin band of vein quartz is often present, varying from about 1/2 to 2 or 3 in. thick, a sufficient evidence of a former water-way for circulating solutions. The walls themselves, and also some of the fracture-planes in

tion of the dip. The hanging wall is less decomposed and is more sharply defined than the foot-wall, apparently having been less subjected to the action of circulating solutions. Sometimes there is a few inches of crushed material along the upper margin

of the dike, and normally it is overlain by a small barren layer of conglomerate. There is no noticeable outcrop of the dike at the surface, and for the first 200 ft. down it is soft and decomposed. A

the dike parallel to the walls, exhibit slickensided surfaces, the striations being approximately at right angles to the strike; that is, they are in the direc-

⁷⁶On the Rand all assays are based on the short ton of 2000 pounds.

section cut from a specimen of the central portion of this dike, in the 15th level cross-cut of the North Randfontein mine, 2090 ft. vertically below the surface, where the dike is fine-grained and dense, was examined under the microscope and found to con-

sist of a plexus of lath-shaped crystals of feldspar in a crypto-crystalline groundmass. The feldspars are turbid through kaolinization; and there are many beautiful examples of cross-shaped interpenetration twins. Numerous minute crystals of iron pyrite are scattered throughout the mass, and a little colorless augite is also present. The assay-value of about the central portion of the dike in the cross-cut on this level, over a width of 3 ft., is approximately 1 dwt. of gold per ton. The average thickness of the dike as obtained from the various cross-cuts in this mine is about 5½ ft., but in places it widens to much more than this. To the north,⁷⁷ in the adjacent Robinson-Randfontein mine, it is only occasionally exposed, and is then poorly developed, having for the most part disappeared into the hanging wall of the 'reef', to again reappear farther north in the next mine. In the North mine it has had a marked influence on the West Reef; both ore and quartzite are blackened, greatly indurated, and exceptionally pyritic. It is particularly noticeable that the upper portion of the banket near the dike contains more gold than the lower portion, while, on the other hand, in the Robinson-Randfontein mine, where the dike is only poorly developed, and is generally absent, the reverse is the case.

Summary

The hand specimens indicate that these 'pebbles' are metasomatic replacements. The microscopic examination of thin sections clearly shows that some of the pyrite 'pebbles' are due to the replacement of original quartzite, and also quartz pebbles; some to the replacement of the quartzitic matrix; and others again to the indiscriminate replacement of both of these.

The fact that in some cases the original structure of the replaced material is still sufficiently retained to be clearly discernible in thin sections under the microscope shows that the interchange has taken place by equal, or approximately equal, volumes: the volume having remained sufficiently near that which it was before the interchange, to preserve, in greater or less degree, the original structure. In such cases the change is usually considered to be molecular; but, if so, it must be governed by some law of multiple proportions, because molecules of different substances vary in size. Thus, if the exchange were molecule for molecule, equal volumes before and after would be the exception and not the rule.

Formation of the 'Pebbles'

Thus the microscopical study of the structure of these 'pebbles' shows that they have been formed in place at a comparatively late stage in the history of the banket by metasomatic processes in every way analogous to the ordinary metasomatic changes with which one is so familiar in normal⁷⁸

⁷⁷At Randfontein the banket strikes north and south, and dips east. The dip in the North-Randfontein mine averages about 72°, and in the Robinson-Randfontein mine about 62 degrees.

⁷⁸The word 'normal' is used advisedly, because the beds or seams of banket are in all important essentials analogous to ordinary gold veins and may be looked upon as

fissure-veins.⁷⁹ Their occurrence shows that they are associated with igneous intrusions in the form of longitudinal diabase dikes; generally also with the presence of carbon; and invariably with ore relatively rich in gold.

(To Be Continued.)

The North Columbia Gold Mining Co., operating a placer property in the Atlin district, British Columbia, reported as follows to the Minister of Mines on its work during 1912. The ground was operated through No. 1 pit, where two lines of pipe are installed, each being 30 in. diam. at the upper end and tapering to 24 in. There are five No. 6 monitors in the pit, each usually with a 7-in. nozzle; and on the dump, a No. 6 and No. 4 machine. Here also is used a 5-ft. flume and block riffles, the average amount of water, including the 'bank-head,' being 4000 miner's inches. A small Sullivan air-compressor was used satisfactorily to operate three hand-stopping drills for drilling the largest boulders, and the large quantity of glacial clay met with in this pit. The clay is in large slabs and must be reduced before going through the sluices. The drills save a great deal of powder. The amount of gravel moved was 310,000 cu. yd., and 16,525 sq. yd. of bedrock stripped. The average depth of banks was 61½ ft. The possible working time was 185 days and actual working time was 154 days. This Company also operates the No. 2 or A. C. pit under lease from the Pine Creek Power Co., Ltd., by means of two main lines of 30 and 28-in. pipe, which taper to 24 in. at the pit. Usually four No. 6 and three No. 4 monitors are kept working in the pit, and one No. 6 and two No. 4 machines are stacking tailing and keeping the tail-race open. A 4½-ft. flume with angle-iron riffles is used. Owing to the flat bedrock, many boulders have to be reduced in size, requiring a heavy consumption of 75% dynamite. There was moved, during the actual running time of 139 out of a possible 178 days, 197,600 cu. yd. of gravel, and 30,805 sq. yd. of bedrock stripped, the average depth of banks being 19¼ ft. Total production was \$72,441, an average value of 36.7c. per cubic yard.

The Pato dredge of the Oroville Dredging Co., Colombia, produced \$13,650 from 18,600 cu. yd. of gravel during the week ended September 9.

Blast-furnaces in South Wales number about 30 and produce about 800,000 tons of pig iron per year, reduced from imported ores.

abnormal quartz veins, the conglomerates having played the part of the fissures and so served as channels in which mineral matter has been deposited from deep-seated circulating solutions. Tin Mining in Tasmania

By PETER G. TAIT

*The northeastern portion of this state has been an important tin-producing centre for over 30 years. It is reached from Launceston by railroad terminating at Branhholm, a distance of 71 miles. The accompanying map shows the situation of the properties mentioned. The Arba Tin Mining Co. is working a 'lead' 400 ft. wide at the bottom and covered by 60 to 80 ft. of overburden. Drilling of 186 holes proved 750,000 cu. yd. averaging 1.9 lb. tin per yard. Two plants are at work, one with a 12-in. Austral Otis pump and a 10-in. gravel pump, and the other with a 12-in. nozzle Thompson pump. The material is sluiced down to the pump, which discharges into a bin about 80 ft. above the bottom, and from here, to lift the sand to the sluice-boxes, a somewhat unusual procedure is adopted, that of haulage by large skips. A double-track haulage line operated from a head-frame on the surface, about 50 ft. high, is equipped with a Jas. Martin & Co. hoist, steam being supplied from a 'jackass' boiler. The depth of the ground now being worked is 139 ft. below surface, and the cost of haulage is 1.5c. per cubic yard. As each part of the ground is exhausted, it is, of course, necessary to erect a new inclined haulage-way and remove the plant. In the last half of 1912, 49,161 cu. yd. of overburden was removed at a cost of 11c. per cubic yard, and 73,440 cu. yd. of drift yielding 0.936 lb. of black tin per cu. yd. at a cost of 13c. per cubic yard. L. B. Mitchell is mine manager.

The Briseis Company

The Briseis Tin & General Mining Co. is working a sub-basaltic river bed, the ancient channel of the Ringarooma river. The so-called northern workings of the Briseis company, which are really south of the present workings in Krushka's flat, are now exhausted, and the ground still to be worked lies under and on the other side of the Ringarooma river. In order to work the northern portion of Krushka's Flat, where the lead has been traced for a distance of 1000 ft., it was necessary to divert the Ringarooma river, and also the main Derby Moorina road. Krushka's flat was originally thought to be too poor to be profitable, and was consequently used as a dumping ground for tailing. Up to the present it has produced 730 tons of tin, an average yield of 3.5 lb. per yard. The official estimate at the end of December gives a total of 800,000 cu. yd. remaining to be extracted, and the yield of tin as 750 tons. These are the main workings at present, and the depth of the ground is about 70 ft., but as work progresses the depth increases. The new road has been completed some time, and the river diversion work is well advanced. This will give several years' work following the lead under the bed of the modern river.

On the Ringarooma hill the difficulty is in the removal of the basaltic overburden. Sluicing is principally adopted, and boulders weighing over half a ton are easily washed down the flumes. A certain

amount of tramming is necessary for the heavier stones. The general manager has considered the question of a more modern system, such as steam-shovels, for doing this work, but, while the actual working costs might be reduced, the capital charges would really make the cost heavier. Up to the end of 1911, the total amount of Ringarooma overburden removed was 1,525,500 cu. yd., at an average cost of 12c. per yard. Tailing from the sluice-boxes is stacked by a 24-in. belt-conveyor, 130 ft. long, working at 33% grade, and stacking 50 yd. per hour. The mine is worked entirely by water-power. To May 1913, the black tin, 74.5% metallic, output has totaled 7075 tons, and dividends on the capital of \$2,880,000 are \$1,440,000. The tin is smelted at the Mt. Bischoff Tin Mining Co.'s plant at Launceston. Lindsay C. Clarke is superintendent.

The Pioneer Tin Mining Co., Ltd., is operating on

SHOWING SITUATION OF TIN PROPERTIES MENTIONED.

one of the tributaries of the main lead, and, as the overburden is not very heavy, the property can be worked much more economically than, for instance, the Briseis mine. Although the ground is comparatively friable, it should be mentioned that in places the cement is 40 ft. thick, and has to be blasted. It varies in depth from 40 to 120 ft., and four plants are installed, two steam, one of 400 and one of 220 hp., and two electric, each of 400 hp., with 16-in. pumps. The smaller steam plant has a 12-in. nozzle pump for utilizing the mine drainage, and a 12-in. gravel pump. In the deeper ground two plants work as one unit. Originally the power was steam only, but the timber areas were being cut out at such a rate that a hydro-electric plant was constructed, and the mean load in 1912 was 482 kw. The cost of electric power at the mine is 0.24c. per unit, against 0.96c. for steam-power. The sluice-boxes are 20 ft. wide and divided down the centre to control the flow and prevent scouring. A swinging belt-conveyor, 500 ft. long with $2\frac{1}{4}$ cu. yd. capacity per minute is being erected to stack the tailing and there will be room for 1,200,000 cu. yd. before any necessity for moving. From 1900 to 1913,

*Abstract from *Mining and Engineering Review*.

there has been handled 5,396,900 cu. yd. of drift, yielding 4526 tons of black tin, equal to 1.878 lb. per cu. yd. at a cost of 13.5c. per yard. The Company's capital is \$960,000, and dividends total \$1,180,000.

The South Mount Cameron company is working terrace ground on top of a ridge about 100 ft. above the Ringarooma, and the problem is to bring water to the ground. For this purpose a power-plant was built on the banks of the river. Water is delivered on the face at a nozzle pressure of 60 lb. by a Mather & Platt pump of 3500-gal. capacity per minute, against a head of 275 ft., driven by an Allen 400-hp. engine. The ground is up to 15 ft. in depth, and of an average value of 1 to 1.5 lb. per yard. In the neighborhood are the deserted Dorset and Ringarooma dredges. The former is now being dismantled and sent to the Philippines for a Melbourne company. The mine manager is H. P. Cecil.

The Clifton Mine

The Clifton tin mine is right at the foot of South Mount Cameron, and within a mile of the post town of that name, on the Bransholme to Gladstone road. It is only two years in May since the plant started to work, and a large area of ground has been treated. The plant consists of a 12-in. gravel pump and 12-in. nozzle pump, driven independently. Both are of Austral Otis Co.'s manufacture. The engine is by W. H. Allen, Son, & Co., and is of 150 hp. capacity, operated at a pressure of 150 lb. The pressure at the nozzle is only 25 to 30 lb. per square inch.

The ground being worked is about ten chains wide, between granite on the one side and a soft pipe-clay formation on the other. There is an overburden of 15 to 20 ft., and the wash is in a comparatively narrow bed of 2 up to 9 ft. The whole ground averages 1.25 to 1.5 lb. per cubic yard. The principal feature of the mine is the water-supply. There is no running stream in the vicinity, and it is therefore necessary to conserve the supply. After floating the barge into its present position, a dam was erected across the cut, and the tailing is run into this pond, from which the clean water is drawn off again as required. By this means it is possible to operate the plant continuously. Mark Ireland is the manager.

The Anchor Mine

The Anchor tin mine, at Lottah, is a large low-grade property, owned by a London company with a nominal capital of \$336,000, of which \$148,800 has been paid up. Two mines are being worked, the Anchor and the Australian mine, formerly owned by the Australian Blue Tier Tin Co. All the work is by open-cuts. At the Anchor the principal faces are known as the Pentridge, Haulage, and Tunnel faces, respectively. At the Pentridge face, the overburden, consisting of decomposed granite, is almost 80 ft. in depth, and necessitates systematic arrangements for its removal. The tin-bearing ore is trammed by gravity to the central crushing station in cars with a capacity of 1.5 tons, and there it passes through one of Hadfield's 'Heelon' gyratory crushers, driven by a Michell pelton. The oversize from this large crusher is further crushed in a No. 4 Gates. From the crushing station to the

mill, 3-ton cars are used, the necessary fall being available to allow the cars to run by gravity. The Australian mine at Blue Tier is about 1500 ft. higher in elevation than the Anchor mine and on the side of a steep hill. Three faces are being worked. The ore from one is trammed to a hopper, and from the two other faces lowered by self-acting trams, the longest being 17 chains, with a drop of 400 ft. All the ore from this mine is transported to the Anchor mill by a Pohlig aerial tramway having a length of 1.75 miles. The towers are up to 40 ft. in height, the longest span being 21 chains, and the capacity 150 tons in eight hours. The tramway is in two stages, a separate crushing station being in use for the Australian mine. The mill consists of two plants, each containing 50 stamps. No. 1 plant is working solely on Anchor ore, as also are 30 head of the No. 2 plant, the remaining 20 head being on the Australian ore. All the plant is driven by water power, and the company has a ditch of 39 miles in length. J. B. Lewis is general manager, his headquarters being in Melbourne.

The following statement gives a summary of the Company's operations during the past year:

Stamps working, average	63
Stamp-duty, tons per day	5.38
Ore treated, tons	104,732
Black tin recovered, tons	188.3
Average tin content, per cent	71.6
Metallic tin per ton of ore, pounds	2.38
Cost of mining, milling, etc., per ton	\$0.84

Gladstone Tinfield

The Gladstone tinfield lies between the Pioneer and the coast, and as water has been rather scarce the Tasmanian Government took over a 12-mile ditch and added 20 miles to it, costing \$134,000 in all. The water now supplies 200 men, as the field is a 'small man's' district. Water is supplied at a price varying according to the market price for tin. When tin is selling at \$576 on the London market, the price per sluice-head is \$1.25 per week for eight hours per day; while it increases 2c. per head for every \$4.80 rise, so that when tin is \$960 per ton, one sluice-head costs \$2.80 per week. On an average, a party of three men purchase two sluice-heads. Payments are made weekly in advance, or, failing this, on a royalty basis. The total expenditure during last year was \$8400. The revenue amounted to \$7700. Tin ore recovered during the last year was royalty scale, 14.9 tons, and fixed scale, 49.9 tons; a total of 64.8 tons black tin.

The Gladstone deposits are for the most part shallow, and do not call for special mention. Recently three pumping plants were put into commission for pumping water from the ditch to the Garfield ridge, a maximum height of 200 ft., but it is only the high price of tin that justifies the payment of a high price for the water, in addition to the cost of pumping.

Pig iron production in the United States during August amounted to 2,545,763 tons, compared with 2,512,431 tons in the same month of 1912. At the beginning of September there were 260 active furnaces.

Vacuum Filtration at the Waihi Mine

By WILLIAM MACDONALD

*This article refers to operations at the Victoria 200-stamp mill of the Waihi Gold Mining Co., situated at Waikino, six miles from the mine. The ore is wet crushed, classified, the sand being leached, and the slime agitated and treated in the plant now described.

As applied to the ores from this Company's property, the vacuum-filter has been an unqualified success, but it might not be applied with equal success to all ores. In a few cases it would not be applicable with any degree of success. In the case

the wash vats to facilitate sluicing out when required. A compressed-air service is provided for all pulp vats for the purpose of keeping the pulp homogeneous and preventing settlement of fine sand on the bottom. The pipes are 3/4-in. diam., spaced about 8 in. apart, and rest on the bottom of the vat. Originally these were laid right across, but difficulty was experienced in clearing the air holes when they were blocked. This was avoided by dividing the air service into two parts, each extending half way across the vats. If a block occurs, the air pressure is concentrated on the particular part affected.

All the vats are fitted with sluicing valves for discharging them if necessary. Each overhead crane

PLAN AND SECTIONS OF FILTER AT THE WAIHI.

of heavy pyritic ores or slimed concentrate, for instance, the capacity of this type of filter would be so low and the difficulty of obtaining a satisfactory wash so accentuated as to put filtration by vacuum out of the question. On the other hand, where the process was suited to an ore, and particularly where an all-sliming policy was considered profitable, a plant similar to the one under review might have a greater capacity and thus work at a reduced cost per ton of slime treated.

The plant at this mill has been in continuous operation since the beginning of 1908, and is in as good working condition today as when erected. Previous to its installation, pressure presses were in vogue, two types of press being used, the Martin and Johnston. The vacuum plant installed was designed to treat 600 tons of slime per day, but is now capable of handling a much larger tonnage.

The filter vats are of 3/16-in. mild-steel plate and rectangular in shape. The pulp vats are 18 ft. 6 in. by 12 ft. 6 in. by 6 ft. deep. The wash vats are 18 ft. 6 in. by 13 ft. by 8 ft. deep at one end and 9 ft. at the other, an inclined bottom being provided to

is operated by a 15-hp. direct-current motor, and is provided with a magnetic brake for exact stoppage. The baskets of filter leaves, of which there are four to each bay, consist of two 8 by 4 by 1/2-in. I-beams, held together with distance pipes and rods. At present 12 filter-leaves are bolted equidistant across the girders. The effective filtering area of each leaf is 124 sq. ft., or 1488 sq. ft. per basket.

There are eight double-acting vacuum-pumps, two of which are held in reserve. The motive power for driving the whole plant is provided by a Crossley suction-gas engine of 200 horse-power.

An analysis of the slime is as follows: silica, 90.80%; iron oxide, 0.82; iron sulphide, 2.48; manganese, 0.43; lime, 0.69; alumina, 2.89; magnesia, 0.15; and moisture, undetermined, etc, 1.74 per cent.

The usual time occupied in a cycle of operations by any basket is as follows:

	Minutes.
Filling	50
Washing	60
Discharging	24
Transferring (three operations)	10
Total time	144

Cloths last from 12 to 15 months, and are treated

*Abstract from Journal of the Chemical, Metallurgical and Mining Society of South Africa.

every three months in a 5% solution of hydrochloric acid. The moisture in the discharged cakes is 30%, and the average amount of gold and silver left in the residue in a soluble form is, approximately, gold 0.048 dwt. and silver 0.022 oz. per ton of dry residue. Total costs of filtering are 9c. per ton of dry slime treated.

Localizing Coal-Dust Explosions

During the 1913 session of the American Mine Safety Association, an exhibition coal-dust explosion test (experiment No. 46) was made at the Bureau of Mines experimental mine, near Bruceetown, Pennsylvania, on the afternoon of September 23, 1913, for the delegates, states mine inspectors, and other mining men. In previous public exhibitions at the experimental mine, preventing or arresting means have been shown only a subordinate feature in the airway, the main points having been to demonstrate to the observers that coal-dust itself would make a violent explosion, and, in addition, in this as one of the series of tests to study the propagation of a coal-dust explosion from point to point through the agency of measuring apparatus. As there are practically no skeptics today in the matter of explosibility of coal-dust, it was decided to use arresting means at either end of the coal-dust loading. It must be clearly understood that the Bureau does not feel that arresting methods are sufficient in themselves, but only useful as secondary safeguards; the important feature is to prevent an explosion from starting; but if it is possible to have the effect of continuous barriers, then an explosion could not be started.

One of these arresting means was a Taffanel stone-dust barrier consisting of ten shelves, which was placed at the end of the coal-dust loading in the main entry. The coal-dust loading extended 800 ft. to the face, thence 50 ft. through a cut through, and out 200 ft. on the parallel air-course. From this point forward for 300 ft. there was a stone-dust zone in which the stone-dust was distributed over the sides and floor after the manner in which it is proposed it should be used continuously in such mine entries where a good watering method cannot be employed. Beyond, or out by both of these arresting zones, was placed additional amounts of coal-dust, so that if the rock-dust did not effectively blanket the flame the propagation of the explosion would be continued, and indicate the ineffectiveness of the devices.

This test was most successful and confirmed conclusions drawn from previous experiments, as follows: (1) It is possible to get a violent explosion in a mine where the surfaces are damp, if there is an ample supply of dry coal-dust present. (2) As a secondary defense, the Taffanel barrier is of great advantage. It is fully recognized that an explosion, such as this, would suffocate all the men in the part of the mine in which it occurred, and hence means to prevent an explosion originating are most important; but if, by any mishap, an explosion should take place in one part of the mine, it would be desirable to have the other parts or other splits defended by such barriers, in order to prevent the

explosion from passing from one section to other sections. (3) A zone treated with sufficient rock-dust will prevent the passage of an ordinary explosion, which is also illustrative of the impossibility of starting an explosion in a well treated zone.

There was one feature of more than passing interest in this explosion, confirming other explosion experiments at the mine, namely, the development of the explosion centre; its passage past cars, and then accumulating in intensity, the back pressure throwing the cars toward the origin of the explosion. The latter effect cannot be considered the result of a wind to fill the vacuum at the face following an explosion, for while this would be influential in throwing light articles, it would be virtually impossible to have caused the hurling through the air of the heavily laden cars.

Mining in Western Australia

The annual report of the Mines Department for 1912 contains the following information: The average value of gold produced per man employed (14,961) on gold mines increased from \$1825 in 1911 to \$1935 in 1912. The average tonnage hoisted per man was 203.64 tons, against 184.94 in 1911. There were 542 men employed at the Collie coal-field who average 544 tons of coal per man, against 539 in 1911. There were 35 fatal and 491 serious accidents in all classes of mines. There were more 'rock outbursts' in the Burbank's Main Lode mine, near Coolgardie. The worst ones happened on No. 6 level, breaking 10-in. timbers and breaking down about 25 tons of ore. In all instances, the outbursts occurred in the lode which is composed of quartz and a somewhat silicified greenstone, the hardness being about six. Under the 'Mining Development Act, 1902,' advances totaling \$212,000 were made to help small miners with their development, drilling, transport, equipment, and subsidies to mills crushing for the general public. The superintendent of state stamp-mills reported that in 35 plants there were 282 stamps available for custom ore, and three 10-stamp mills leased under agreements. There were 1026 lots milled, totaling 56,636 tons of ore, while there was treated 18,600 tons of sand, 8085 tons of slime, and 5330 tons of tin ore. The Government lost altogether \$44,600 on the year's operations; but the indirect benefit to the mining industry is a large one. Since 1898 the state mills have treated 900,416 tons of gold ore, 496,109 tons of sand, 101,068 tons of slime, and 56,883 tons of tin ore, yielding a total of \$19,100,000. There were 2992 useful boilers and 3113 groups of power-driven machinery in all districts, including 121 suction-gas producer plants.

Gold production of Western Australia is showing an improvement, as up to May 31, 1913, it was valued at \$10,699,000 against \$10,593,000 in the same period of 1912.

During August the Elmore vacuum plant at the mines of the Sulitjelma company, Norway, produced 832 tons of copper concentrate.

Use of Miners' Safety Lamps

By JAMES W. PAUL

*Safety lamps that were defective or were not properly cared for have caused a number of accidents in foreign coal mines. Many miners in the coal mines in this country have been burned with the flame of gas (methane) that was lit by opening a safety lamp or by not using the lamp properly. Safety lamps from which the gauze had been removed have been found in the hands of inexperienced or careless men in gaseous mines. And no doubt many mine disasters have been prevented by discovering such ignorant use of safety lamps and warning the men so carelessly inviting injury or

A recent pattern, oil-burning safety lamp, bonneted. *a*, steel hood; *b*, steel bonnet; *c*, iron gauze, outer; *d*, iron gauze; *f*, asbestos washer; *g*, brass ring, middle; *h*, brass standards (five); *i*, glass globe; *j*, cotton wick, flat; *k*, copper pricker; *l*, porcelain burner; *m*, insulated tube; *n*, asbestos washer; *o*, brass ring, lower; *p*, brass ring; *q*, brass oil fount; *r*, wick adjuster; *s*, electric-current contact.

death. Defects in miners' safety lamps caused at least two disasters in this country in 1912. The lamps were of the modern type, burned naphtha or gasoline, and had a double gauze, a shield, and a glass globe. In each disaster a safety lamp ignited gas within a mine. In one case 12 lives were lost, and in the other case several men were severely burned. The first of the two disasters resulted from the parts of a lamp not being properly assembled. The top asbestos gasket was doubled on itself, so that a part of the glass did not touch the gasket, and an open space was left between the top of the glass and the gauze. When this lamp with the gasket doubled back was lighted and placed in an explosive mixture of gas and air, the gas within the lamp flamed and ignited the gas outside the lamp. The second disaster was caused by a safety

lamp that had not been properly assembled. In assembling this lamp, the pull bar that works the scratcher for igniting the tape had been left out. This lamp when lighted and placed in an explosive mixture of air and gas ignited the gas outside the lamp.

Assembling Safety Lamps

Any safety lamp is presumed to be in a safe condition only when all its parts are properly assembled in the manner prescribed by the manufacturer. All manufacturers of safety lamps, upon request, furnish illustrations of their lamps showing each part and the completely assembled lamp. Some of the errors common in assembling lamps are:

1. Leaving out one or both gaskets, or using broken gaskets.
2. Placing gaskets in underfed lamps so as to exclude the air from below.
3. Leaving out one of the gauzes in double-gauze lamps.
4. Placing on top of the glass an expansion ring designed to be placed under the glass.
5. Placing the expansion ring upside down, thus destroying its usefulness.
6. Failing to screw the bowl (fount) sufficiently to make a tight fit between the glass globe and the gaskets.
7. Leaving out the igniting device without plugging the stem hole.
8. Leaving off the deflection rings that prevent air from blowing directly into the lamp.
9. Leaving off the shield or bonnet when the lamp is to be used in a strong current of air.
10. Placing a defective gauze in a lamp.

Hammer Drills in the Witwatersrand

The following report of work done on the Witwatersrand G. M. Co., Ltd., shows what can be done with small hand machines when there is a scarcity of labor. Six hand rotation jackhammers ran on the Witwatersrand G. M. Co., Ltd., for five months from July to December, 1912, continuously, taking up foot-wall in hard rock. The method of handling the drills was to allow one drill, weight 54 lb., per native, on contract at 1d per foot drilled, with one jumper carrier and a white boss on each three machines. The average footage obtained per drill per eight hour shift was 28.7 feet, the average depth of hole drilled being four feet, the most suitable to the mine's working condition. These six drills have been responsible for 150 tons of foot-wall broken per day during the period. This includes block holing or re-drilling broken rock which was too big for handling. The mine authorities express themselves completely satisfied with the work done, which is peculiarly significant, in view of the present shortage of native labor.—*South African Mining Journal*.

The pottery imported into the United States in 1912 was valued at \$9,555,530, but the domestic production, according to the U. S. Geol. Survey, was valued at \$36,504,164. The exports were valued at \$1,177,784. The domestic production was 81.4% of the total consumption, against 78.9% in 1911.

*Abstract from U. S. Bureau of Mines publication.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Under-Estimating the Cost of Milling Plants

The Editor:

Sir—The editorial comment in the issue of August 23 on 'Under-Estimating the Cost of Milling Plants' inclines me to fear that my article, published in the issue of July 21, has been somewhat misunderstood. It was not my intention that a reader should infer that there existed any friction between the machinery houses and the metallurgical engineers. Such a condition would, I consider, be deplorable, and work a hardship on the operator. I certainly agree with you that the closest relationship should exist. And this means that each attend to his own particular line of work, leaving alone that which rightfully belongs to the other, thus working together for the best service to the operator. I believe that, generally, such a relationship does exist, except where interfered with by unthinking, unintelligent, or would-be economical operators.

The intelligent metallurgical engineer realizes the necessity for a close relationship with machinery manufacturers. He is not a designer of machinery; he only knows the exact work he wishes to perform; the machinery manufacturer must design such machinery and supply all data concerning its mechanical superiority and efficiency for this particular work. But the question of whether or not this particular work is going to be the proper thing for the treatment of the ore is not for his consideration, but solely concerns the metallurgical engineer. Judging from letters received from a few prominent machinery manufacturers, since publication of my first article, a universal close relationship of this sort would greatly please machinery dealers as well as engineers, and greatly benefit the operator.

I agree with you that "no two general managers or board of directors will agree as to most economical and efficient method of mill construction"—unless they have had the experience of at least one installation. After having had this experience, I believe that they will generally agree; and the fundamental principle which might well be called 'horse sense' will consist in the employment of a competent metallurgical engineer to properly devise treatment of ore, select properly designed apparatus for efficient service, lay out proper arrangement of such apparatus into an efficient and economical installation, all regardless as to whether the mill is built by a mining company, machinery house, or contracting engineer; and only when the 'horse' is a mule will they conclude with any other general program.

Referring to the example you mention "where identical equipment for a 10-stamp mill, when erected and placed in operation under the supervision of a competent engineer, was 40% in excess of a contract price offered by a machinery house," it is

unquestionably true that a piece of work may often be done more cheaply by one person than another, but into such wide variance certainly the factor of competence or the question of whether finished installation would have been identical, must surely enter.

With your permission, I will add a reply to the criticism of Chas. Hutchinson, which appeared in the issue of August 30. Mr. Hutchinson's criticism of my diagnosis of under-estimated costs of milling plants, in the issue of August 23, is most interesting in its terseness, but I fail to find much room for an argument; we seem to be, generally, of one opinion. But a bit of a reply might be of interest. He starts by saying that he cannot agree with all of my conclusions, but upon reading his remedy it is found to fit my diagnosis almost perfectly. He lays the blame for under-estimated costs on the buyer, the superintendent who desires to hold his job, and the mining engineer-superintendent untrained in such specialized work. This is largely true, and it is just such cases that I have recorded in detail in my second article. Also, just such cases are referred to in my third article when I stated that the data for the notes had been largely secured by going over plans and specifications handed me for examination; those "atrocities in the form of mill plans submitted by mine superintendents." I have certainly not advocated mill installations by mine superintendents or mining engineers, but attempted to make the same point which Mr. Hutchinson has undoubtedly made stronger.

I cannot agree, however, to Mr. Hutchinson's remedy as he has stated it, although it may be splitting hairs to take up the point. He advises: (1) a metallurgical engineer to devise treatment; (2) a mechanical engineer to design plant; (3) a contractor to make installation, as being the most satisfactory method of securing the most efficient plant at the lowest cost. The old saying "Too many cooks spoil the broth," applies here admirably. And if it is spoiled, or if any portion or all of the plant fails, who is to blame? Where does the responsibility lie?

The metallurgical engineer devises treatment, and is through; his responsibility ends when he turns over his flow-sheet to the mechanical engineer, and he cannot be held responsible for mistakes, misinterpretations, or the injection of the mechanical engineer's ideas which might affect operation as planned.

The mechanical engineer designs the plant, as per flow-sheet, as nearly as his lack of knowledge of metallurgy, and usually his lack of knowledge of conditions under which construction and operation must be carried on, will permit him, and is through. His responsibility ends when he turns his plans over to the contractor, and he cannot be held responsible for mistakes, misinterpretations, or the injection of the contractor's ideas into his own, nor for the mistakes of the metallurgical engineer, or alterations desired later.

The contractor makes the installation, as per plans, as nearly as his lack of knowledge of metallurgy or application of items of equipment will permit him, and is through, and cannot be held responsible for

efficiency of equipment nor for results of treatment.

You are dealing with three specialists in a case where neither knows enough of the others' part of the work to enable him to do his own intelligently. And if they are all three employed on the job independently, the conflicts, if not absolutely serious, at least cause much annoyance and delay; and the Lord help the man who has to operate the plant, and the owner. I was once acting as an 'under-study' for a general manager of a mining company during construction of a plant where there was just this combination, and I hope never to have the experience again.

It sounds like the logical and most efficient arrangement, and it is, in many undertakings; but in a milling plant, especially where any chemical treatment is employed, such as cyaniding, the almost impossibility of preparing plans and specifications in such absolutely finished and perfect a manner that all details may be properly completed, precludes its adoption. There are many details about a milling plant which the metallurgical engineer has clearly worked out in his own mind, but which are very difficult to put on paper in such a manner as to be sure of correct interpretation; and many points have to be taken up by him as the work progresses, and decisions made as changing conditions are met.

As Mr. Hutchinson says, "it would appear futile to call attention to an ill without proposing a remedy," I wish to offer as a remedy the following:

(1) Employ a metallurgical engineer to devise treatment (allow him to employ a chemist to assist him if necessary).

(2) Retain the same metallurgical engineer to design the plant and estimate the cost (allowing him to employ a mechanical engineer if necessary).

(3) Retain the same metallurgical engineer to make the installation (allowing him to employ a constructing engineer if necessary, or to let contracts to machinery houses or to the contracting engineer if desired).

Mr. Hutchinson says: "If you are ill, send for a doctor. If prison stares you in the face, send for a lawyer. If you wish to develop a mine, send for a mining engineer." All of which is most excellent advice. But in this instance you have three distinct matters in hand: you are ill, you fear prison, and you have a mine to develop; while in the instance under discussion you have but one matter in hand: the installation of a milling plant to treat a certain ore. Which is, from the first step to the last step, the business of a metallurgical engineer. It constitutes the definition of the name.

I quote: "Of all the engineering professions, the engineering contractor is the only one who pays for his mistakes." Not so! The metallurgical engineer who makes a failure of an installation pays much more dearly by loss of his reputation than does the engineering contractor who loses a few dollars on a job. It is true that one hears but little about such losses by metallurgical engineers, but this is due to the too frequent application of the three-cornered method of making an installation, just discussed, where responsibility cannot be

placed. All hands slip out from under, and the operator's loss is all that is heard about.

With these two points of difference out of the way, I pass on to the part in Mr. Hutchinson's criticism with which I heartily agree. He says: "As a matter of fact, the machinery houses have for years made practically all the mine superintendents' estimates for them, gratis." Correct! It is upon this fact that I based my first reason for under-estimated costs, as set forth in my first article in the issue of July 21. Mr. Hutchinson says in his first sentence: "Under-estimating the cost of milling plants is the rule rather than the exception." This with the other quotation given above, shows clearly how entirely he agrees with me in this matter.

I, too, would be glad to see all machinery dealers shut down on this sort of thing. Dealers, engineers, and operators would all be greatly benefited. Metallurgical engineers only require from dealers such information as price, specifications, and records of performance of the equipment they manufacture or offer for sale, and this must be supplied them if the dealer expects to have his equipment specified. (By the way, right here I might say that the dealer who keeps the metallurgical engineer fully supplied with such data for his 'dope' book is the one who will get the most of that engineer's business, other things being reasonably equal.) In return, the metallurgical engineer is glad to reciprocate by supplying the dealer with data and information regarding performance, cost of operating, repairs, general efficiency, etc., of various equipment he may be using, also all sorts of general engineering data from the field. Which, in turn, the dealer dispenses to other engineers, buyers, superintendents, etc., as Mr. Hutchinson states.

Just one more item. It was certainly not intended that the idea be conveyed that the cost of allowing a machinery dealer to pay for a lunch was a source of expense to the buyer. The clause referred to was intended to convey a broader significance. The visiting in town of superintendents and engineers is often the source of unnecessary expense, not only in money expended, but in time lost. I have seen a construction crew wait while the superintendent finished the round of entertainment extended to him in the city.

The further statement that "the most direct route to a buyer's affections is by way of his stomach" is doubtless quite generally true, and especially when it is realized that it may be at least the most direct route known to the dealer, who may not be the 'people' Josh Billings referred to. However, the route is an enjoyable one sometimes, especially when the dealer's expense allowance does not call for too limited a ticket; and I must admit that any expense incurred by the buyer in this connection might have been omitted as an item of under-estimated cost, as, after lunches, dinners, and other convivial entertainment, the buyer is as apt to secure concessions wanted from the dealer, in the way of a few extra 'spares' thrown in, a better delivery agreement, an additional percentage off, etc., as the dealer is to book the order. In which case, a bit

of 'carelessness' on the part of the buyer in the matter of settling the score could be overlooked.

A. SYDNEY ADDITON.

San Francisco, September 13.

[That there should be no real cause for friction between the metallurgical engineer and machinery manufacturer is unquestioned, and where such cases have existed, they have undoubtedly been the exception rather than the rule. We agree with Mr. Addition that while the respective provinces of the metallurgical engineer and machinery manufacturer are separate and distinct, a closer coöperation would redound to mutual benefit.—EDITOR.]

Mineral Flotation.

The Editor:

Sir—I have read with interest Mr. Hoover's book on flotation and also the article by Edward Walker in your January issue. Having been closely connected for a number of years with both the Minerals Separation and De Bavay processes working on the large scale in Australia, I hope that I may be allowed a little space in your journal to offer a few remarks on this subject. In comparing the De Bavay process with the Minerals Separation process in operation on Broken Hill ores, many factors have to be taken into account. In the first place, De Bavay has been one of the few companies to recognize that in the treatment of Broken Hill tailing it does not pay to treat the slime product, owing to its high percentage of lead. By rejecting this slime it has been found that not only is a higher grade and consequently more profitable zinc concentrate produced, but the slime itself is kept on hand as a valuable by-product. Mr. Walker remarks that experience gained during the past year has gone to prove the efficiency of the Minerals Separation process over the De Bavay process. This certainly does not appear to be the case, judging by the enormous profits made by the De Bavay company in spite of paying high prices for tailing. Also, an interesting point in this connection is the fact that the South company, after various trial runs, decided that, from a commercial point of view, at any rate, De Bavay was the best process. This certainly does not point to the process being inefficient as compared with the other processes on Broken Hill ores. From a profit-making point of view, the De Bavay process is ahead, at the present time, of any other process in Broken Hill on Broken Hill tailing. I do not refer to the slime treatment. At the present time there is not much profit in this treatment, but it is hoped that the experiments which are being conducted by the South mine, Amalgamated Zinc, and other companies will be crowned with success. Mr. Walker further states: "Moreover, there is little likelihood of the De Bavay process being applied anywhere else than at Broken Hill, as it is obviously of inferior efficiency to the Minerals Separation process." Why obviously? In the first place, Broken Hill is not the only lead-zinc mining centre in the world, and also, with their present knowledge, the De Bavay people could greatly simplify the design of their plant, making it cheaper to erect. Mr. Walker would be greatly surprised if he knew the actual working costs of

this process. I regret that professional etiquette prevents me from giving the information. The recoveries also are very high, higher than given in Mr. Hoover's book, where a crude value for the tailing is conveniently assumed. Both the De Bavay and Minerals Separation processes have their scope on different types of ore. The De Bavay process will treat material through 30-mesh with 5 to 10% slime, much coarser than can be treated by the Minerals Separation process without crushing. For very fine grained ores, however, which are eminently suitable for the Minerals Separation process, the De Bavay process is not so good. In experimenting with the De Bavay process, the method described by Mr. Hoover in his book is not suitable, as it will give bad results on any ore; and, although I have personally conducted numerous experiments on the De Bavay company is more up-to-date and more used anywhere, the methods referred to above. The stepped cone of rough design shown in Mr. Walker's article I have never seen on the De Bavay plant, as I am pleased to say that the engineering skill of the De Bavay company is more up to date and more original than this design would lead one to believe. The De Bavay process stands as a model of Australian management and metallurgical skill so lightly spoken of by Mr. Hoover. In reference to the Minerals Separation process, it is not generally known that it is really a development of the Cattermole process. The first plant erected at the Central mine was really a large Cattermole plant using Wilfley tables. On observing the tailing from these tables, falling into the tailing-boxes, a large froth was seen floating on the top of the boxes. Immediately the Central mine staff planned out the scheme of the flotation box, and the treatment was modified accordingly. It will be seen that this process was made commercially successful by the Central mine staff, and that Australians had no small share in its development. Thousands of pounds of profit was made by the Minerals Separation process on zinc tailing before Mr. Hoover's single level apparatus, which is undoubtedly the finest mechanical feature of the present plants, was introduced. To Mr. Lavers, chief metallurgist of the Minerals Separation Ltd. in Australia, is also due the rapid advance of this process in dealing with copper ores, owing to his brilliant research on the adaptability of eucalyptus and other oils to the treatment of these ores without the necessity of the use of acid.

WILTON SHELLSHEAR.

Mt. Morgan, Queensland, May 8.

The United States produced more white arsenic in 1912 than ever before, the output for last year being 3141 short tons, valued at \$190,757, as against 3132 short tons, valued at \$73,408, in 1911, according to a report on the subject by Frank L. Hess, just issued by the U. S. Geological Survey. The imports in 1912 were also the largest on record, amounting to more than 6156 short tons, valued at \$428,741, as against 4096 short tons, valued at \$247,323, in 1911. The only white arsenic produced in the United States was that made as a by-product of smelting operations.

Special Correspondence

LONDON

COPPER MINING IN THE RUSSIAN EMPIRE.—DREDGING TIN IN THE FEDERATED MALAY STATES.

American engineers are doing a large part in the work in connection with the development of copper deposits in the Russian Empire. A good deal has been written with regard to the Kyshtim company owning a property in the Southern Ural region. The same controllers are now bringing forward the Tanalyk property, situated a few hundred miles to the south in the direction of Orsk. The Tanalyk Corporation was formed in London, in April 1912, for the purpose of purchasing the entire share capital of the South Urals Mining & Smelting Co., the Russian organization owning the property. The capital is £300,000, of which £190,000 is represented by the shares of the Russian company; in the balance-sheet on December 31 last, £73,011 is shown to have been advanced in cash as working capital to the Russian company, and £37,999 cash remaining in hand. The latter has been spent since then, as well as other money advanced on loan. It is now proposed to issue additional shares of the Russian company and for the Tanalyk Corporation to subscribe for the whole of them. To provide the money, a debenture issue of £200,000 is to be made, and £200,000 new shares are to be created. Of the shares, 66,000 will be held against conversion of the debentures, and 50,000 placed under option to the Inter-Russian Syndicate, otherwise Messrs. Beatty and Hoover, at £3 per share until November 1916. A statement has just been issued, checked by R. Gilman Brown, of the various properties and their present state of development. The most important mine is the Mamhet, which is being developed in two parts. The workings are down to 165 ft. and the lode has been found to average 10 ft. The ore assays from 2 to 3% copper and about 8 dwt. gold and 10 oz. silver per ton. These figures are not exact, but are intended to indicate an average of those in the report, which show considerable variation. The developments at the Tanalyk mine have not given such good results; two veins 3 ft. wide have been found averaging 2 to 3% copper, 3 to 4 dwt. gold, and 2 oz. silver. Lower-grade ore is found at the Troitsk shaft, useful as a flux for mixing with the other ore. The estate belonging to the Company contains timber and coal. A seam of coal 7 ft. thick has been disclosed in a prospecting pit 22 ft. deep, and it promises to yield a fuel suitable for metallurgical operations. Early this year it was stated that the presence of zinc in the ores was causing anxiety. It is now announced that no difficulty will be caused in this direction. A smelting plant to produce 1500 tons of copper per year is now in course of erection. The first half should be in operation early in 1914. It is estimated that the copper will contain 14 oz. gold and 244 oz. silver per ton. The average content of the ore reserve, figured by Mr. Brown at 70,000 tons, is given as 2.9% copper, 7.4 dwt. gold, and 7.5 oz. silver.

The winning of alluvial tin by means of bucket-dredges is making a gradual advance. Most of the work hitherto has been done by various modes of sluicing or by pumping the gravel to a floating barge containing the tables. I recently referred to the first bucket-dredge supplied in Nigeria. In Siam, the Renong and Tongkah companies are dredging stanniferous sand on or near the seashore. More recently the Malayan Tin Dredging Co. has started operations in Perak. The most recent accessions in this class of work are the Ipoh Tin Dredging and Kampong Kamunting companies. The Kampong Kamunting Tin Dredging Co. has been formed by Messrs. Pratten and Freeman in Sydney, New South Wales, to acquire a tract of alluvial tin ground at Kamunting, three miles from Taiping, the capital of Perak. Among the engineers who have reported on the property is M. T. Nelmes Bluck, who was recently the manager of the Tongkah Harbour Tin Dredging Co., an Australian venture to the north of the Malay district. The deposit consists of sandy gravel with com-

paratively little clay. Over 300 bores have been put down, and from the information so gained, 384 acres are estimated to contain 18,000,000 cu. yd., averaging $1\frac{1}{4}$ lb. cassiterite per yard. The average depth is 30 ft., and the bottom is soft clay. The proposition is eminently suitable for bucket-dredging. Two dredges with 7-ft. buckets are to be erected, and the cost of working is estimated at 9c. per yard. The capacity of each dredge is calculated at 75,000 yd. per month, and the total output of the two dredges at 80 tons of cassiterite per month. The capital of the Company is £150,000 in £1 shares, of which 80,000 shares is the purchase price, 50,000 shares are offered for subscription, and 20,000 held in reserve. The cost of in-

MAP OF MALAY PENINSULA.

stalling the two dredges is estimated at £40,000. The Ipoh Tin Dredging Co. has been formed in London to acquire a tin-gravel property six miles south of Ipoh, in the Kinta valley. Reginald Pawle is on the board, and M. T. Nelmes Bluck is consulting engineer. H. D. Griffiths, late of the Tronoh, examined the property. The property has been selectively mined by previous Chinese owners, and the ground is now suitable for bucket-dredging. The average depth of the deposit is 42 ft.; and the total ground 11,306,240 cu. yd.; 100 acres average $1\frac{1}{2}$ lb. cassiterite per cubic yard, 40 acres $1\frac{1}{4}$ lb., and 38 acres $\frac{3}{4}$ lb. It is proposed to build a dredge with 10-ft. buckets, capable of treating 100,000 cu. yd. per month. The cost is estimated at 9c. per cubic yard. The deposit consists of a sandy gravel, and the cassiterite is very fine, so that the saving apparatus will have to be carefully regulated. The capital of the Company is £90,000, of which £43,500 in shares and £7500 in cash is purchase price. The 46,500 shares offered for subscription have been underwritten.

NEW YORK

THE CARIBOU-COBALT MINES CO. AND CONDITIONS AT COBALT.—GRANBY COMPANY'S AFFAIRS.—RAY, BRADEN, MASON VALLEY, AMALGAMATED COPPER, CALUMET & HECLA AND THE MINERS' STRIKE.

The event of greatest interest in the past week was the debut of the Caribou-Cobalt Mines Co. This Company, which is controlled by E. P. Earle, David Fasken, and others who are prominent in the Nipissing company, has a capital of \$1,000,000 in \$1 shares. The Company has taken over the old Drummond mines, which have an output record of 2,200,000 oz. silver. These are in the Kerr lake portion of the Cobalt district, the total area of the property being 71 acres. It is at present producing about 45 tons of ore per day and is equipped to yield 100 tons. Trading in the shares was brisk during the week, and they were bid up to 58c. The board of directors consists of the two men mentioned and W. B. Randall, president; S. T. Baylis, vice-president, and Richard F. Greene, secretary and treasurer. The market sponsor for the stock is Baruch & Co., the firm which was prominent in the flotation of the Goldfield Consolidated. Some dejection has

been caused in Cobalt producers by the announcement that the American Smelting and Refining Co. has set a 7% limit on the arsenic content of Cobalt ore. Shipments from the district last week amounted to 439 tons of ore, and as the smelting plants at Copper Cliff and Carnegie have been shut down for some time and the Orillia plant is in process of being rebuilt, the burden falls on the DeIoro and Thoroid plants. As both of these are taxed almost to capacity by the shipments of the companies by which they are controlled, the situation presents some inconvenience. Good progress is being made in draining Kerr Lake, and it is expected that the water will all be out before winter sets in. All the signs point, therefore, to somewhat of a revival of interest in Cobalt.

The Granby has issued its annual report, which shows a gratifying increase in the prosperity of that excellent, but in some respects unfortunate, company. It will be remembered that this Company, which has the all-embracing title of Granby Consolidated Mining, Smelting & Power Co., Ltd., built a huge smelting plant at Grand Forks and was proceeding merrily when, in 1910, it was discovered that the actual ore reserves were less than one-half the amount stated by the mine manager. Consternation and recrimination followed, and when a bond issue was floated, a while ago, the underwriters had to take almost the whole issue. Last year an excellent new mine was acquired at Hidden Creek, British Columbia, and nearly 8,000,000 tons of 2.2% copper ore has been developed. A 2000-ton smelting plant has been built near the mine, which is on Observatory inlet, British Columbia, and will be ready to begin work by the end of this year. The property at Grand Forks and Phoenix has paid \$4,750,000 in dividends since 1900, but as the investment in lands and plant is given in the balance-sheet as \$15,000,000, and as the property there only has a life of five or six years more, the greatest hope of profits is based upon the new mine. The net working profit for the year ended June 30, 1913, was \$1,214,600, the copper produced amounting to 22,688,644 lb. This was produced at an average cost of 10.64c. and sold for 16c. After paying \$450,000 in dividends, \$683,149 was transferred to the surplus. The Ray Consolidated is making a good showing, as the tonnage handled continues to increase. At the Braden 77,304 tons of ore was milled, yielding 1,332,000 lb. copper. The recovery in the old mill was 71% and in the new mill only 57%, due to a shortage of sulphuric acid. The Mason Valley has been suffering from a shortage of ore for its smelter since the Nevada-Douglas has been short of smelting ore for some time, and is now reported to be about to erect a 100-ton leaching plant. The Mason Valley smelter receives ore from a number of properties, but with the exception of the Nevada-Douglas, they are all small, and the total is not great. As a result, Mason Valley shares declined from 7 to around 3½. The directors of the Amalgamated will meet soon to declare a dividend, which will undoubtedly be at the usual rate of 1½% for the quarter.

The Osceola has reduced its quarterly dividend to \$2 and most of the other Calumet & Hecla subsidiaries may doubtless be expected to reflect the strike in decreased dividends. The president of the Calumet & Hecla, Quincy A. Shaw, has made public a statement controverting the allegations made by J. A. Walker, of the American Federation of Labor. Mr. Shaw points out that his salary is \$15,000 per year, not \$300,000. The hours for men under the contract system are nine, and arrangements are being made to reduce them to eight wherever possible. The payrolls show that the average net wage of miners is \$3.66 and trammers \$2.89 per day, after deductions have been made for hospital assessment and the aid fund. The Company now has over 3000 men at work, and over 1500 at work underground. Mr. Shaw goes on to say that "this trouble has not come from our men, but from an element outside which has attempted for its own purposes to take control of the labor field. We have with us hundreds of men who own their own houses, who are bringing up their families in a way creditable to the district and the country, and our relations with them even during this trouble have never changed. It is a business as well as a sen-

timental proposition that a contented working staff is the first requisite for real efficiency in any undertaking, and that is what we have always kept in mind in our relations with our employees."

PORCUPINE, ONTARIO

DOMES MINE AND MILL.—TOUGH-OAKES AND TECK-HUGHES MINES.

The trouble in the directorate of the Dome Lake company arising out of the lack of information regarding the physical condition of the mine and the unsatisfactory financial position of the Company, appears to have been settled. At the adjourned meeting a report on the mine was submitted, and it would appear that while the grade of the ore is satisfactory, the ore occurs in short and disconnected lenses. Other portions of the property are so far not fully developed, but seem to be of greater promise, and the possibilities of the property are by no means exhausted. At the meeting it was shown that there was a total indebtedness of \$61,000, with pressing debts of \$18,000. The General Assets, Ltd., which formed the Company, and which has charge of its affairs, are creditors to the extent of \$41,000. The shareholders authorized an increase of the capital by 250,000 shares, par value \$1, of which 100,000 shares will be sold at a discount. The General Assets has agreed to take stock at par for its claims, and the returns from the sale of the 100,000 shares will be used to make alterations to the mill and to provide complete electric equipment. It is understood, however, that there will be no money left over for working expenses, and that an additional \$25,000 will be needed for this purpose.

The results obtained at the Dome during the period from April 1 to August 31 are as follows:

	Tons milled.	Gold produced.
April	9,863	\$129,333
May	10,852	148,499
June	11,300	98,216
July	11,150	75,958
August	10,720	67,660
Total	53,885	\$519,666

Working costs for the first five months of the fiscal year show a reduction of \$1.09 per ton as compared with the figures published in the annual report, and in August the reduction was \$1.55. Operating costs at the present time, including current development, are about \$4 per ton, and when the addition to the mill is completed, they should show a further reduction. Good progress is being made with the installation of the additional 40 stamps to the mill. The concrete work has been finished and the erection of the steel has been started. The Company proposes in future to issue monthly statements covering tons of ore handled and gold recovered.

The management of the McIntyre mine states that the production for September will be in the neighborhood of 7500 tons. The new mill is in operation and satisfactory results are being obtained. In the Swastika district, both the Swastika and Lucky Cross mines have been closed. The former suffered from a shortage of both ore and money, and is not likely to be reopened, but it is stated that work will be resumed on the Lucky Cross in a short time. At Kirkland Lake, which lies only a few miles from Swastika, the Tough-Oakes property, formerly known as the Foster, has opened good ore to a depth of 200 ft. While cutting the station at the 200-ft. level, the porphyry was encountered, and, while it is not definitely known what effect this will have on the grade, it is the general opinion that the small high-grade veins, such as are found in this district, will not persist very far into that formation. Driving is being carried on at the 100-ft. level, and results to date have been satisfactory. This property has every appearance of being the most profitable one in the Kirkland Lake district, although it is probable that it will never be a large mine. Indications throughout the district point to there being only two or three compara-

tively small mines, and recent unsatisfactory developments in several properties have resulted in a decline in interest. In sinking the Burnside shaft, the porphyry was cut at a depth of about 35 ft., where the profitable ore was cut off. The shaft was continued vertically to a depth of 100 ft. and a cross-cut driven into the conglomerate to prospect a vein which showed on the surface. Where opened, there was 10 in. of high-grade ore, but sufficient work has not been done to justify any opinion as to its ultimate value. The results of future development on this vein will decide whether or not the property will be purchased by those holding the option, as the terms of the option call for a heavy payment to be made in a short time. On the Teck-Hughes property at the west end of Kirkland lake, development on the 100-ft. level of the No. 1 vein, which was found in the porphyry, proved disappointing, and it was decided to abandon this shaft and concentrate work on No. 2 and 3 veins, where ore of a satisfactory grade has been found on the surface. The ore-shoots, however, appear to be short, and it is doubtful if a sufficient quantity of ore can be developed to give a reasonable return on the capital which would have to be invested.

MELBOURNE, AUSTRALIA

MT. MORGAN.—NEW MT. LYELL ACQUISITION.—NORTHERN TERRITORY OIL.—VICTORIAN RETURNS.—NEW SOUTH WALES MINING LAW.—BROKEN HILL PROPRIETARY STEEL WORKS.

At the Mount Morgan mine, Queensland, work is being pushed for the introduction of pyrite smelting, which it has been decided to adopt, and it is anticipated that the first furnace will be blown in next March. Besides this new smelting plant, there is also being erected a concentrating plant capable of treating 500 tons of ore per day. This plant is to cost \$268,000, and in the meantime an experimental unit is at work and is said to be surpassing expectations. In other words, the process of change to which this great mine has been subjected during the last decade is still in progress. It was in 1906 that its first copper plant was erected, and since then the mine has been regarded as mainly a producer of copper, despite its wonderful gold yield. Perhaps even the latest innovation will not prove to be final.

The Mt. Lyell company continues to absorb small properties near its own, and the latest to be acquired is the West Lyell, a mine sold many years ago in London under the high-sounding title of The Copper Mines of Mount Lyell West. The property was one of which a local satirist sang in lines that were quoted far and wide, where the Company's policy of employing three highly paid officials, a manager, a metallurgist, and an accountant, and merely beating time and development work:

"There are three to work above ground, and five to work below,

At the famous copper mines of Lyell West;

There are three to do the figuring, and five to find the show,

At the famous copper mines of Lyell West;

There are four to see the other four their duties do not shirk;

There are four whose mission 'tis to do the labor of a Turk;

There's a very fair division—four to boss, and four to work,

At the famous copper mines of Lyell West."

And so the poem went on to the humorous suggestion that there was room for many another well-paid official on the surface: a cook (presumably to cook the estimate of the value of the ore that was not there), a chaplain, and so on, and finished up with the suggestion that the services of the miners might be dispensed with. Now, this ground, on which about \$96,000 was squandered, having been abandoned at last, has been acquired by the Mt. Lyell company, 'free, gratis, and for nothing.'

What looks like a shocking case of 'error' has been brought to light. Some months ago a company was formed in Melbourne to take up certain areas in the Northern Territory of Australia supposed to be petroliferous. An expert, who was sent to report on the cession, has reported

these areas to be valueless. He states that "samples of petroleum of a superior quality, known as a paraffin base, and capable of producing an illuminating oil after refining, were brought to Melbourne about seven years ago. Under sworn declaration, it was stated to have come from a gorge 10 miles from Rocky Bar, a large tributary running into Shoal reach, as shown in the British Admiralty chart of the Victoria river. There was no difficulty in locating the spot designated in the declaration, after traveling thereto by saddle and pack-horses from the Victoria River depot, situated about 90 miles from the mouth of the river. After careful and close investigation of this neighborhood, I could not discover any indication whatever either of petroleum or oil-bearing formation." This sort of thing is unfortunately all too common in Australian mining.

The mineral returns for the state of Victoria for the year 1912, are late, as usual. They show a total decline of 9.4% on the figures for the previous year, the decline in gold, which in Victoria is all important, amounting to 4.7%. Coal has decreased 10% in tonnage and nearly 14% in value. There is nothing else of importance.

The New South Wales Mining (Amendment) Bill, 1913, now before the State Parliament, provides, *inter alia*, for

MAP OF EASTERN STATES OF AUSTRALIA.

depriving lessees of mineral leases of the statutory right to exemption from the performance of the labor conditions, to the extent of one month for every six-month period during which double the required labor was employed. The maximum period of exemption under this clause of the existing act is only six months, so that it would not have been thought any objection could be made. However, if the new bill becomes law, even that trivial degree of security will be taken away from the mining leaseholder. The reason put forward for the proposal to abrogate the right is that it is unnecessary, in view of the existence of a clause providing that suspension for six months may be obtained from the warden (mining magistrate) for any reasonable cause; but there is this difference, that under this clause an exemption is a favor, whereas under the existing act a lessee is entitled first to six months' exemption as a right, after which he is at the point at which he is now desired to be, as soon as work ceases on his property. Parliament should try to liberalize the leasing conditions, instead of seeking to still further restrict leaseholders.

Operations at the Broken Hill Proprietary Co.'s iron and steel works' site, near Newcastle, are going ahead rapidly and smoothly. The New South Wales Government is carrying out its part of the undertaking, having already dredged the river along part of the waterfront to a depth of 25 ft., where the previous depth was only 10 ft. At this point the Company is building a pier where the heavy machinery, which has been ordered, will be landed. Some parts of the rolling mill will weigh 40 tons. The traveling crane to be installed on the pier will have a capacity of 60 tons. This wharf is already connected with a temporary railway for the transport of the machinery to the various sites. At all of these the necessary foundations are now being built.

KALGOORLIE, WESTERN AUSTRALIA

MINES IN THE SOUTHERN CROSS DISTRICT.—KALGOORLIE COMPANIES INVESTING IN FOREIGN COUNTRIES.—SHAFT-SINKING ON THE 'GOLDEN MILE.'—YUANMI, VICTORIOUS, AND SONS OF GWALIA MINES AND MILLS.

The additional five stamps and tube-mill have been started at the Bullfinch mill, and from August 6000 tons will be treated monthly. The grade of ore mined will be considerably reduced, as the reserves, when the plant started, were estimated at 177,300 short tons, worth \$11.08 per ton, whereas for the five months ended July 31 the grade treated has been \$14.40 per ton. On December 31, 1912, the Company was in debt to the bank for \$130,000, and to sundry creditors for \$29,900, a total of \$159,900. Since then a profit of \$225,000 has been earned, so that the Company is getting into a strong financial position. With an output of 6000 tons at the reduced grade of \$11.08 per ton, it is anticipated that the current rate of profit will be maintained, and that the Company will soon be in a position to pay dividends. The main orebody in the mine, known as No. 3 lode, is now striking northwest with the rocks of the district, and is being opened on all three levels of the mine. The original rich east and west ore-shoot, which yielded very rich ore nearly three years ago, does not appear to go down, and cannot be found below No. 2 level. Since starting the mill, late in April, the Corinthian North has treated 8889 tons, yielding \$29,100, with \$46,000 left in the residue. The mine is being equipped with an all-sliming plant of the same capacity and similar to the plant on the Bullfinch. This will be completed next month and is expected to be running regularly in October. When in full operation, a monthly profit of \$24,000 is expected. The lode on this property extends on the surface a distance of 2650 ft., and for the 900 ft. proved at 100 ft. averages 17 ft. in width and \$8.50 per ton in value. At 200-ft. the value for 250 ft. driven is \$10.50, and in a winze below that level, as high as \$18 to \$21 per ton. This mine looks as if it would before long become one of the big properties of Western Australia.

Since abandoning the option on the Great Victoria mine near Southern Cross, the Great Boulder Proprietary Co. has been looking far and wide for a new property to succeed the Great Boulder when it is exhausted. It is now announced that an option has been secured on a mine on the Cleveland peninsula, Southeast Alaska, and that the engineer, Frank Leahy, is to take charge of operations. Up to date, fully a score of Western Australian mining companies have scattered profits earned in this state all over the world, and not one of their outside ventures has proved a success. The Great Boulder company has cash resources of fully \$750,000, is still treating 18,000 tons of ore per month, yielding \$235,000 and a profit of \$125,000, and paying yearly dividends amounting to \$1,312,500. On December 31, 1912, the ore reserves amounted to 731,300 short tons, of the recoverable value of \$12.62 per ton, equal to 40 months supply for the mill. Richard Hamilton, the general manager, has apparently made up his mind that the lode has passed into the Golden Horse-Shoe for good, as shaft-sinking has been stopped for two years at 2880 ft., the lode having passed into the Horse-Shoe at a depth of 2480 ft. Another company which is widening its sphere of operations is the Associated, which has taken an in-

terest in the Keeley mine, near Cobalt, in Ontario. This mine is reported to have opened a rich 3-in. silver vein. A mine with such a small vein would not be considered by any English company if situated in Australia. The Associated mine during 1912 treated 125,169 tons of ore, yielding \$805,000, and paid a dividend of \$61,900. The ore reserves on March 31, 1913, were estimated at 500,000 tons, of a recoverable value of \$6 per ton, or about four years' supply for the mill. The liquid assets on March 31 were \$650,000. Since the year closed, the mill has been treating 10,800 tons per month, returning \$64,200 and a profit of \$6200. The deepest shaft at the Associated is only down 2285 ft., and it has been at a standstill for over two years. Since the present manager, Duncan McAulay, took control in September 1911, he has reduced the development expenditure from \$1.08 per ton, or \$11,000 per month, to 72c. per ton treated, or \$7700 per month; but the whole of this expenditure has been at or near the surface. Mr. McAulay's policy seems to be a mistaken one. When one considers that some of the richest ore-shoots opened in the Golden Horse-Shoe or any other of the mines are now being developed at 2480, 2630, and 2780 ft., the moribund condition of the Associated is still more inexplicable. Even the Lake View Consols, which suspended sinking operations in February 1905, at 1845 ft., and did not resume sinking till seven years later, in April 1912, has now found that a mistake was made, as good ore is being opened at a depth of 2100 ft., to which depth both the shaft and a winze have now been sunk. In no other country in the world have directors in recent years suspended operations, on encountering a barren or impoverished zone, as they have done in Western Australia. The Kalgurli company is another example. In June 1910 the main shaft was completed to 1900 ft., and a new Fraser & Chalmers hoist, capable of hauling 2 tons from 3000 ft., had just been installed. Because the 1750-ft. and 1850-ft. levels subsequently proved unprofitable, the shaft has not been sunk one foot since.

At the Yuanmi mine, controlled by Bewick, Moreing & Co., the sulphide mill, that is to operate with the oxide mill, has just been started. The new plant consists of an Edwards duplex roaster with 60 rabbles, a No. 8 Krupp ball-mill, rotary drier, ore-bins, elevators, and conveyors, of 100-ton daily capacity. After being crushed and roasted, the ground sulphide ore joins the oxidized for regrinding, agitating in cyanide solution, and vacuum-filtration. A 100-hp. Crossley gas-engine has been added to the one of 200 hp. to drive the additional plant, and wood gas is supplied by a down-draft wood generator, which consumes ordinary 5-ft. lengths of firewood, in addition to scrap wood, chips, sawdust, etc. This generator was built at Hoskin's foundry, in Perth, and is claimed by Bewick, Moreing & Co. to be a Commonwealth generator. However, the Cambridge company, of England, which has all along had its generators made by Hoskins, assert in writing that it is an infringement of their patent, and is really a Cambridge. A lawsuit is pending. According to calculations based on figures issued by Bewick, Moreing & Co., this gas generator, consuming wood costing \$3.84 per ton, effects a saving over a Crossley generator, consuming charcoal costing \$14.16 per ton, of 74c. per ton of ore treated, or \$74 per 100 tons treated. The proportion of wood consumed to charcoal is 171 to 100 tons. Although a fair proportion of the tonnage treated by the mill on the Associated Northern's Victorious leases, Ora Banda, during July, came from the stope above the intermediate drift between the No. 4 and 5 levels, and was worth \$60 per ton; the average of the tonnage was only \$4.52 per ton. G. M. Roberts concludes from this that the sulphide gold was lost and discarded with the residue. To make sure of this, 100 tons has been carted and railed to the Company's Kalgoorlie sulphide plant to make a thorough test. If the loss is confirmed, an Edwards roaster and Krupp ball-mill, on the lines of the new Yuanmi sulphide plant, will be installed at the Victorious. The cost of transporting the ore to Kalgoorlie is \$3.60 per ton for the ore now being experimented with. No. 6 level in the Victorious has been driven 100 ft. in ore ranging from \$16 to \$21 per ton.

General Mining News

ALASKA

CORDOVA

There is considerable excitement at Seward and the western districts over the reported discovery of another gold-placer district. Gold valued at \$1200 has been brought by Olsen and Gatchell to Knik, which was recovered under difficulties. The location of the new placer find is northeast of the Matanuska coalfields and about 110 miles distant from Knik, and possibly a little farther from Chitina, via Willow creek and Copper Centre, and then along the Tazlina river to the mouth of the Nelchina river. The formation of the country is similar to all the placer camps of the North, being a mica-schist and limestone. Low, rolling hills, indicating an erosion which has formed the placers, are characteristic of the country. There is a scarcity of timber in the immediate region of the find, but there is plenty of water. Forty claims have been recorded at the Knik office, which include the Nelchina country. Knik is the nearest settlement and the logical gateway from

MAP OF ALASKA.

this district to the new camp, which is 110 miles from Knik and about 248 miles from Cordova.

JUNEAU

August operations of the mines on Douglas Island may be summarized as follows:

	Alaska Mexican.	Alaska Treadwell.	Alaska United.
Development in ore, feet.....	79	49	449
Development in waste, feet....	6	61	257
Broken ore, decrease, tons.....	11,817	11,529	1,607
Stamps working	120	540	240
Water power, days	30.7	24.3	24.0
Steam power, days		5.6	13.1
Electric power, days		12.2
Ore crushed, tons	19,740	80,973	38,661
Concentrate treated, tons	413	1,647	890
Gold by amalgamation	\$18,103	\$102,426	\$48,867
Gold by cyanidation	20,342	100,574	42,459
Total realizable value	38,060	200,971	90,414
Net profit	9,094	95,368	29,342

FAIRBANKS

During the summer, 85 men were employed at No. 17 Goldstream, and the season's clean-up is estimated at \$136,000. Peterson, Craig, and Johnson control this property. Many men have returned to Fairbanks from the rush to the Shushana district, and declare that there was nothing to justify such a stampede. 'Pay' was found on only three claims; no townsite has been established, and all routes are difficult to travel over.

IDITAROD

Work at this centre has been retarded during the season owing to shortage of water. The Guggenheim dredge has operated steadily and its yield is said to be equal to the

average. A dredge is to be constructed next spring by Riley and Marston.

NOME

The people of this place are working hard to get things in order again, but a great deal of damage was done by the flood, especially in destroying food supplies. The *Nugget* is printing a small sheet under difficulties. That paper of September 13 and 20 contains the following items: The estimated output of gold from seven 'outfits' on Jess creek will be \$30,000 for the season. Over \$9300 is claimed as wages by men working on a dredge at Windy creek, and a suit has been filed against Hugo R. Johnstone. A. H. Moore has about 45 men working on No. 3 Iron creek at sluicing, and results are encouraging. The Pioneer Mining Co. will prospect some of its claims during the winter, and No. 4 on Holyoke creek will be operated by F. R. Cowen and J. W. Ferguson. This is said to be the richest claim in the Nome district, and has been the cause of litigation. The property of the Golden Dawn Mining Co. is also rich, and now that litigation has been settled work will be continued through the winter. There are 175 people at Candle, and rich gravel was opened by A. Oleson on C bench of Candle creek. Nome was visited by a heavy storm on September 13, 1900.

ARIZONA

COCHISE COUNTY

According to the 1913 mining edition of the *Bisbee Daily Review*, a well arranged publication of 94 pages dealing with the mining industry of Arizona, there are approximately 25,000 men employed in mines, mills, and smelters in the state; the output of copper ore in the current year will be about 5,500,000 tons yielding 400,000,000 lb. of copper; there are six large copper-ore concentrating plants and eight smelters, the latter having an annual capacity of 421,000,000 lb. of copper; and the assessed valuation of all Arizona producing mines, exclusive of equipment, is \$113,524,544. The publication deals with all phases of mining and other industries in Arizona, and should be of interest to mining men generally.

GILA COUNTY

The eighth unit of the Ray mill at Hayden is complete, and a total of 9000 tons per day can be treated. This last unit contains several new features, and the others will be remodeled on these lines. A No. 7 Cameron sinking pump is to be installed in the Reymert shaft, near Superior, where a large flow of water was recently opened.

GREENLEE COUNTY

The furnaces at the Arizona Copper Co.'s new smelter at Clifton are now running well, according to L. D. Ricketts. The furnace foundations were faulty and one of them 'froze up' recently.

MOHAVE COUNTY

At the Boundary Cone mine the west drift on the 520-ft. level shows 4 ft. of \$70 gold ore. The property was recently visited by some shareholders, and a mill may be erected. On the 200-ft. level of the Pioneer, at Oatman, 8 ft. of \$30 ore has been opened. The adit of the Hot Tamale, at Chloride, is in 400 ft. in good ore. A large shoot of \$15 ore has been opened on the 100-ft. level of the Pittsburgh. Good shoots of siliceous copper ore have been opened on No. 1 and 2 levels of the Pinkham, and shipments will be started soon.

CALIFORNIA

The oil industry of California is to be thoroughly studied and a report issued by the State Mining Bureau, under F. McN. Hamilton, state mineralogist. The work will contain full information upon every phase of the industry.

MONO COUNTY

The number of employes of the Standard Consolidated mine, at Bodie, has been considerably reduced, while it is probable that the hydro-electric power-plant will be sold to another company operating in Nevada.

NEVADA COUNTY

The Pennsylvania Gold Mining Co. is being sued for \$50,000 by the widow of Greseppe De Bernadi, who was

killed in the Herman mine, operated by the Company, near Westville, Placer county, in March last.

SHASTA COUNTY

It is reported in Redding that H. F. Wierum, consulting engineer for the Balaklala Copper Co., has secured a six months' extension of the option held on the Hall process. He will return to Coram and complete erection of the gas plant, which is being constructed in Los Angeles. The Mt. Bally Gold Mining Co. has opened 30 ft. of ore, 2 to 7 ft. wide, worth up to \$20 per ton in gold, at its mine in the Whiskeytown district.

SIERRA COUNTY

The Kate Hardy mine, about two miles from Forest City, will probably change hands shortly. At the Hardy Kate, the shaft being sunk to cut the south extension of the Kate Hardy vein, is down 265 ft., and a cross-cut will be driven about 30 ft. west from this point. A washing plant has been built at the Miners' Home gravel mine at Howland Flat, and work will be conducted with 20 men during the winter. The Wide Awake, White Bear, Red Ledge, and other claims are being actively worked.

SISKIYOU COUNTY

The Black Bear mine is being developed by the Rollin Mining Co., which has a 100-hp. hydro-electric plant and air-compressor in operation. Development from the 460-ft. level is promising, and the 16-stamp mill will probably be in operation within 60 days, crushing the ore now being developed.

TUOLUMNE COUNTY

(Special Correspondence.)—Rich ore has been opened north of the shaft on the 300-ft. level of the Dutch mine, at Quartz, this week. The vein is streaked with gold, and no estimate can be made of the richness of the ore. The same shoot yielded a large amount of gold in past years, but was lost at the 400-ft. level, and it has not been worked above the 300-ft. level. The mine has for some years been under the management of C. H. Segerstrom, of Sonora, and has been a profitable producer. A few months ago it was decided to do extensive development work in the deeper workings, and to sink the shaft below its present depth of 1800 ft. Adequate equipment was installed to carry out the plans, and simultaneously the work of dewatering these levels was begun. The 1500-ft. level is now above water, and in a few weeks more the deep-mining campaign will likely begin.

The Springfield Tunnel & Development Co. proposes to increase its capital stock from \$200,000 to \$500,000, and a meeting of directors for this purpose will be held early in November. According to the best information obtainable, the Company has outlined extensive development. Local men are reopening the old Bonanza mine, situated in the northern part of Sonora, and will operate the property on a small scale. The property has produced several hundred thousand dollars, but has not been worked to any great extent in late years. The Tuolumne Deep Channel Mining Co., with a capital stock of \$100,000, has filed articles of incorporation in this county. The directors are W. R. Groves, C. W. Heinecke, H. L. Prettyman, and W. S. Brown, all of San Francisco. Articles of incorporation of the Black Oak Mines & Mill Co. have been filed here. The capital stock is \$1,000,000, with shares at \$1 each, and the directors are G. Coonan, F. O. Harrington, B. Van Alstine, K. M. Pryor, of San Francisco, and H. C. Quackenbush, of Pierre, South Dakota.

Sonora, October 11.

COLORADO

The northern coal-mining companies of the state have increased the price of coal by \$1 per ton on October 6, on account of the miners' strike in the southern fields, where the price has not been raised.

CLEAR CREEK COUNTY

(Special Correspondence.)—A 10-in. vein has just been opened in the adit being driven in the McClellan mine on Leavenworth mountain. Assays show 375 oz. silver and 18% lead, and shipments have been started. J. Laffey is operating under lease. A. Robert, leasing on the Vir-

ginia City, on Lincoln mountain, is shipping carloads of ore which return a settlement of 145 oz. silver and 30% lead. Twelve men are employed in dismantling the old machinery at the Pelican mill preparatory to installing the Edison rolls. The new equipment has been ordered and will arrive during the next few days. J. B. Ballantine, engineer in charge, expects to be ready to start ore treatment early in January 1914. The new rails recently ordered for the Capital adit have arrived, and track laying will be started next week. The electric motor has arrived and there is considerable activity about the premises. This trolley system is being installed by the Onondago Mining Co. in lieu of being granted a right-of-way through the Capital workings. Electric drills are to be purchased for use at the Prudential property on Republican mountain. T. W. Cunningham and B. J. O'Connell will make the improvements, holding a lease on 750 ft. of ground to the west on the Magenta-Turner vein. Shipments are being made from the East Griffith mine on Griffith mountain. Operations are carried on through the adit-level, and stoping is in progress on a 6-in. streak of galena that mills \$70 per ton in silver and lead. F. A. Maxwell is manager. David Kennedy, owner of the Centennial mine, has started a test shipment of 500 tons of ore which will be treated at the Capital mill. In the event that the anticipated results are obtained, a similar plant will be constructed.

Georgetown, October 7.

GILPIN COUNTY

The Bull Moose Mining Co. is working two shifts at the Richardson mine, in Russell district, and good ore is being extracted from the Bobtail vein. Smelting ore is valued at \$30 to \$40 per ton, and the mill 'dirt' returns 1.5 oz. gold per 'cord' (8 tons). The Pine Comb group in the Wide Awake district is being developed by Missouri people. The Bates Leasing Co., in Chase gulch, shipped over 100 tons of ore to the Iron City mill for concentration, and four tons of smelting ore to the sampling works. In Silver creek, the Reform adit is to be driven to 250 ft. Ore shipments average up to \$52 per ton. Sylvanite ore has been opened in the Hot Tamale lode in Silver creek, and the Golden Rod Mining Co., of Chicago, will prospect its claims this winter. The U. P. R. mill produced 110 oz. of \$17 gold last week. Shipments of ore and concentrate from Black Hawk during September totaled 3175 tons.

GUNNISON COUNTY

Mining in the Pitkin district has not been very active during the current year. On Gold creek the Carter Tunnel is the only large adit property doing any amount of work. The adit is in 7731 ft., and from the end of this Carrol M. Carter is driving a four-compartment raise 1100 ft. to connect with the old Volunteer shaft, which is 300 ft. deep. A few small veins have been cut. Little can be said regarding the Raymond, Gold Links, Balzora-Basick, Sandy Hook, and others on the creek, as not much development has been done this summer. It is well known that these properties could be worked profitably.

On Quartz creek the Brant Independent Mining Co. has been busy all summer on the Copper Mountain adit, which is being driven to cut the Roosevelt vein. This adit is in about 1700 ft., and although a large vein was cut, it was not the Roosevelt vein, and the adit will be continued until it reaches the objective point. The Fremont is also being developed by local men.

OURAY COUNTY

The Revenue mine will be operated during the winter. C. R. Wilfley states that the Barstow mine will be shut down indefinitely, as the ore reserves are almost exhausted. Since 1909, the output has been \$300,000.

SAN JUAN COUNTY

The Silver Lake property, near Silverton, has been leased by the American Smelting & Refining Co. to Messrs. Mears, Pitcher, and Slattery. About 100 men will be employed in this well developed lead mine. Steady work is going on at the Kittimac, Queen Ann, Mayflower, and King mines, and by various syndicates.

TELLER COUNTY (CRIPPLE CREEK)

On October 20 the Portland Gold Mining Co. will distribute a dividend of 2c. per share, equal to \$60,000, making a total of \$9,397,080 to date. There are 30 sets of lessees at the Stratton Estate mining over 2000 tons of ore per month. During September the Gaylord mill treated 1200 tons of \$3.50 ore with 80% extraction.

The Carbonate Queen claim of 10 acres, on Battle mountain, has been acquired by the El Oro Mining & Milling Co. for \$75,000. A shaft is down 600 ft., and 3000 ft. of development has been done, the yield being about \$100,000. The Arkansas Valley Railway, Light & Power Co. has a coal reserve of nearly 18,000 tons to provide against a possible shortage due to the strike of coal miners. This

MAP OF CRIPPLE CREEK DISTRICT.

power company supplies 7000 hp. to the district, including pumps at the Golden Cycle mine, 10 different ore-treatment plants, 22 electric hoists ranging from 5 to 175 hp., 14 air-compressors, and many small motors. The hoist safety device invented by C. R. Welch, of the Portland mine, had a satisfactory test during the past week at No. 2 shaft of that property. The engine was run 'wild,' but was automatically checked with plenty of spare room.

IDAHO

Robert N. Bell, state mine inspector, was recently in Wallace, Shoshone county, and stated that there was considerable activity in Blaine county.

BLAINE COUNTY

The geological formations and topography of this county were recently described in a special issue of the *Wood River Times*, of Hailey, by Stewart Campbell. He says that Blaine county being situated in the south-central part of the state, comprises almost the entire southern drainage area of the Boulder mountains, a branch of the Sawtooth range which projects from the general mountain area into the wide open country of southern Idaho known as the Snake river desert. The drainage is all tributary to the Snake river, having a general southern course conforming with the trend of the range. Throughout the greater part of the county the mountains rise from 500 to 3000 ft. above the valleys on the southern border and reach an elevation of from 9000 to 12,000 ft. above sea-level, where they culminate into peaks and ridges at the watershed. The most notable is Mt. Hyndman, with an elevation of 12,048 ft., being the highest peak in Idaho. In its structure, the geology of Blaine

county is complicated. The oldest rocks are sedimentary in origin, consisting of limestones, sandstones, quartzites, shales and slates. Ore deposits occur in many parts of the county, the principal districts being Smoky, Wood River, Muidoon, Lost River, and Boulder. Each district is a comprehensive study in itself. The principal minerals are galena and zincblende, containing silver and gold. The veins occur both in the lime and granite. Since the deposition of the orebodies there has been a general upheaval and readjustment which has faulted all of the veins, thus causing extensive and skillful prospecting to be carried on continuously if the mines are to be permanent producers. Due to this faulting and unskilled operations, the majority of the mines in the county are at present lying idle, but the day is not far distant when they will again become steady producers. The Wood River mining district is that part of Blaine county drained by Big Wood river, lying south of Ketchum, east of the Smoky and Big Wood River divide, and west of the Big and Little Wood River divides. The principal towns are Hailey, with an elevation of 5333 ft.; Ketchum, which is situated 12 miles farther north, with an elevation of 5823 ft.; and Bellevue, which is five miles south of Hailey, with an elevation of 5150 ft. The principal mines are situated on the west side of the river, the silver-lead veins occurring in both limestone and granite. From 1879 to 1890 the annual production was about \$1,500,000, when, with the decline in price of silver the camp was nearly shut down. The total production from the district to date amounts to over \$60,000,000.

The area including the Wood River mining district is situated near the contact of the early Carboniferous formation, and the later granite intrusion with the former occupying the larger area. The sedimentary rocks consist of limestone, sandstone, quartzite, shale, and slate; the granite intrusion is quartz-diorite and granite. The intrusive character of the granite is apparent and shows plainly at all contacts. The veins in the Wood River district occur both in the sedimentary and granite area, the principal mines, however, being in the sedimentary formation. All of the veins have a general northwest and southeast strike, with a dip to the south of from 30 to 60°, and vary in width from a few inches to 40 ft. The walls are generally well defined and are often highly polished. In the Star mine, situated on the west side of Wood river, between Hailey and Bellevue, the vein cuts through both the sedimentary and granite area and seems to carry the same mineralization in each rock. The principal mineral in all of the veins is galena, containing also silver and zincblende. The principal gangue is siderite, calcite, and occasionally quartz and ground-up country rock. The ore forms regular lenticular bodies of solid galena to irregular masses of galena and country rock, but as a general rule the ore is clean enough to be shipped without milling, except when combined with zincblende. The veins are faulted and seldom continue for any great depth until the orebodies are intersected with a fault plane, thus compelling continuous and intelligent prospecting to be carried on ahead of the ore extraction. Due to the fact that many of the veins are faulty and practically all of the mines were poorly managed, the district is stagnant and there is not much development that shows intelligent operation. The mines that were intelligently developed have been worked to a considerable depth and have been continuous producers, which proves the fact that the orebodies are permanent in depth and that all the district needs is intelligent operators.

SHOSHONE COUNTY

The negotiations under way for a settlement of the suit pending between the Caledonia and Bunker Hill & Sullivan companies appear to have been practically completed. In the event of the final consummation of negotiations, the Caledonia is to be granted the right to run an incline raise from the Kellogg tunnel of the Bunker Hill to the Caledonia workings, thereby giving the former company an additional 300 ft. of depth to its orebodies, the Caledonia ores to be trammed out through the Kellogg tunnel on the electric line of the Bunker Hill, and the Caledonia is to

have a lease on one unit of the east mill of the Bunker Hill. In consideration for these concessions, the Bunker Hill company is to receive stock in the Caledonia company.

MONTANA

SILVERDOW COUNTY

During the last ten days of September the Butte & Superior mill treated 1130 tons of ore per day, and the total yield of zinc concentrate for the month from 30,870 tons of ore was 5777 tons, an increase of 225 tons over August. The average extraction was 90.09%, and the concentrate assayed 52.27% zinc.

NEVADA

ESMERALDA COUNTY

The enlarged and timbered shaft at the Oro mine is now below 500 ft. in silicious rock containing pyrite. On the 500-ft. level of the Blue Bull, a cross-cut has developed 6 to 14 in. of \$15 to \$45 gold ore, with some silver and copper. The 700-ft. cross-cut has also opened the Victor vein. Three to four feet of \$16 ore is being developed on the 300-ft. level of the Victor mine of the C. O. D. Consolidated. From the Jumbo Extension's property 45 tons of ore per day is shipped to the Bonnie Claire mill. Development at the Sandstorm-Kendall is showing promising results. Water has interfered with sinking the 500-ft. level winze. At 670 ft. east of the Kendall shaft, on this level, the cross-cut has passed through 20 ft. of ore, 7 ft. of which is worth \$2 to \$5 and a small streak on the foot-wall assays \$44 per ton.

MINERAL COUNTY

A large vein of high-grade cinnabar has been opened at Cinnabar by Al. Drew, and the district is much interested. The quarries of the Nevada Black & Gold Marble Co., of Denver, at Mina, have been sold, and considerable equipment will be installed.

NYE COUNTY

The No. 4 hole of the Railroad Valley Co. was drilled 763 ft. in 62 hours, and at 660 ft. passed through the formation mentioned in this journal of October 4. No. 5 hole is being drilled 1¼ miles from No. 4, and was to have been finished last week.
